Much has been written recently in our local press about the tyranny of labor and the corruption of the labor-unions, but everybody cognizant of the facts and willing to recognize them knows that the blame for the disorganized condition of industry in San Francisco belongs to both sides—to the employer as well as the employee, to capital as well as labor. A few days ago the directors of the Panama-Pacific Exposition of 1915 had to explain why they had given the printing of the official history of that exposition to a firm in New York. It appears that G. P. Putnam's Sons did it for \$30,875, whereas the local printers demanded more than \$50,000. It is also a curious fact that the four bids made in San Francisco were very close, ranging between \$52,503 and \$54,260. Was that a strange coincidence? Not at all; it is explained by the existence of a combination, the Printers Board of Trade, that kills honest competition. The first man to be asked for an estimate claims his victim and no member of the combination is allowed to submit a lower estimate. Similar conditions obtain among employers in other local industries. Chicanery undermines fair dealing. If, for example, the price of labor or of raw material is increased 10%, the manufacturer passes the burden on to the consumer; and not only does he do that but he takes the opportunity to profiteer outrageously. The increase in labor or raw material may represent only 2½% of the *total* cost of the product, so that the remaining 7½% is added arbitrarily under cover of a necessary re-adjustment. The labor-unions are ineffective because they cannot maintain their solidarity, and their failure to act as a unit is due first to their inability to persuade all the workers to join, and second to the corruption of their leaders, many of whom make terms with the combination of employers. Industrial adjustments are vitiated by 'politics', that is, deals and bargains of an underhand kind, involving disloyalty on both sides. Thus when the printer employees made their outrageous demand of a 48 hours pay for 44 hours work, the printers were unable to take a firm stand. Nearly half capitulated at once and the others held together for a few days only, having neither the courage nor the loyalty to resist an imposition of the gravest kind. Is it any wonder that Los Angeles attracts the manufacturer? It is all well enough to 'boost' San Francisco and to raise money for 'bull' campaigns, but what San Francisco needs is honesty among both its workers and its employers; it should establish and maintain a real system of collective bargaining, not a miserable vendetta varied by graft and trickery galore. The spirit of the days of Schmitz and Ruef survives; the briber is still deemed better than the bribed; a demagogue still sits in the mayor's chair and the whole system of public control is rotten from top to bottom. Instead of building bridges on paper and trying to advertise San Francisco with flapdoodle, it would be well if our people realized that local industrial and individual prosperity depends upon fair dealing and honest work, not upon double-dealing and sculduggery.

Valuation of Placers

In this issue we publish an article that is of particular interest because it discusses a subject that has not been accorded the attention it deserves, namely, the estimation of the value of alluvium containing gold and platinum. The author is Mr. Gerald H. Hutton, whose wide experience as a dredge operator gives his opinions more than ordinary weight. The estimation of the precious-metal contents of a placer involves, first, the sampling of the ground, and second, the interpretation of the results of such sampling. That erroneous conclusions have been reached frequently in this work is indicated by the number of dredges that have been abandoned long before the anticipated yardage has been mined, and by the still greater number of dredging enterprises that, after years of active operation, have barely returned the capital investment without any reasonable profit to the owners. As Mr. Hutton points out, the ingenuity and resourcefulness of dredge-engineers has been directed toward mechanical improvements and refinements with the object of reducing the cost of operation and increasing the recovery of precious metal. In this they have been remarkably successful. In the modern dredge, wood has been replaced by steel for the construction of the hull and a large part of the superstructure; the size of the buckets has been increased to such a degree that as much as 15,000 cubic yards per day can be excavated by a single machine; the design has been perfected, and superior grades of manganese-steel have been used in bucket-lines and tumblers, with the result that the dredge can eat its way through almost any material except solid rock or cemented conglomerate. In their efforts to reduce the operating cost, dredge-men have adopted heat-treated alloyed steel for bucket-pins and similar parts; they have taken advantage of the economies effected by welding with the oxy-acetylene flame and with the electric arc, and by using the oxy-acetylene torch for cutting metal; they have systematized and standardized their operations to the point where, as Mr. Hutton declares, dredge-mining can be done under favorable circumstances for as low as $5\frac{1}{2}$ cents per cubic yard. We venture to add one highly essential factor to those enumerated by Mr. Hutton as accounting for a remarkably low operating cost: competent and efficient management. The omission was probably intentional, and perhaps excusable, for the reason that Mr. Hutton is well known as the engineer who is directing the three successful dredging enterprises of the Metals Exploration Company at Gold Canyon, in Nevada, and at Marigold and Junction City, in California. The good work done in reducing the cost of operation serves to emphasize the apparent neglect of the pre-requisite to profitable exploitation, namely, the ascertainment that the deposit under consideration is sufficiently rich in gold or platinum to warrant the investment of the capital necessary to mine it. Although the general principles applicable to the appraisal of any mining property are not dissimilar, the task of sampling and valuing dredging ground accurately has inherent features that make it difficult. Mr.

Hutton points out some of these features; he gives concrete examples to show the wide variation between the anticipated and realized recovery from specific blocks of ground; and he presents in detail his method of adjusting the data derived from drilling reports, and computing the unit-value of the ground. He declares frankly that he is not yet satisfied with the procedure, and urges other engineers to contribute their ideas and the results of their experience, to the end that better methods may be developed. Such an exchange should benefit all; we welcome discussion of Mr. Hutton's paper.

The Making of a Career

The mining profession is remarkable for the variety of men it includes and the diversity of the training that they have undergone. As all roads lead to Rome, so all kinds of preparation seem to have sufficed to develop the character and stimulate the ability of the young engineer to such a point as to open the portals of a successful career. Presumably the correct inference is that force of character cannot be gainsaid if opportunity be given. The many interviews that we have published show that the leaders of our profession have been most variously, and, sometimes it may seem, unequally educated, in so far as a conventional curriculum is implied; yet the inequalities of the start—the varying handicap, as it were—have failed to hold back the genuine men, the hard workers and honest thinkers, the true votaries of science as applied to industry. We have recorded conversations with those who were graduated from famous colleges and with those who as boys thought themselves lucky if they could get hold of an occasional textbook for reading during the intervals snatched from manual labor. Not many of our subjects have been graduates from recognized mining schools; partly because the School of Mines as an institution for preparing mining engineers was only just becoming established when our veterans were boys. Nowadays every civilized country has a School of Mines, and we in the United States can boast one in each of the principal mining regions. Among these is the Colorado School of Mines, which, despite its chequered career, has produced many useful men, among whom is Mr. James L. Bruce, whom we interviewed recently in his office at Butte, Montana. From Dublin to Butte does not seem a far cry, thanks to Marcus Daly and other Hibernians, but Mr. Bruce only happened to be born in Ireland, and it seemed extremely unlikely forty years ago that he would ever develop into a leader among mining engineers in Montana. He owed his liking for mechanics to his father; and to that parent's migratory life he likewise owed his first contact with mining, in Colorado. There he became attracted to the digging of ore by meeting those who were engaged in the industry at a time when the goldfields of Colorado, particularly Cripple Creek, were in the ascendant. Like other successful and useful men, he worked his way through college, that is, he earned the money needed for the purpose, interrupting the regular scholastic course in order to engage himself as a chain-man and

draftsman with a firm of surveyors at Cripple Creek. Such breaks in a college course may be a handicap in some ways, but they do serve undoubtedly to add to the seriousness of purpose with which the student renews his studies. Like everybody else he obtained his start through the kindness of a senior; we all did that; none of us was worth his salt when he started; somebody had to be a fairy godfather to us. Not everybody, however, remembers and records his gratitude, as Mr. Bruce has done, to those who gave him his first chance.

The surveying department is a good ante-room for mining engineering, if the young man be not too content to remain there, because it brings him in contact with operations underground and gives him an opportunity to study the geologic relations of ore deposits. Mr. Bruce seems to have had a persistent desire to avoid undue absorption in the purely technical work, but to acquire knowledge of the business of mining in its broadest sense, more particularly in connection with the management of men and the administration of affairs. For his flair in this direction he may be indebted to the Scottish factors from whom he is descended; at all events, he showed early a keen appreciation of the basic idea that the chief purpose of mining is to make money, not to test interesting processes or to investigate the origin of ores, neither to develop the waste places of the earth nor to spoil the scenery of the beautiful ones. This being his notion, he was fortunate in becoming associated with Mr. J. R. Finlay, who in practice and in theory, as his book on 'The Cost of Mining' proves, is a disciple of the truly utilitarian phase to which Mr. Bruce was an early and sagacious convert. Then he met another, and even more famous, exponent of the same school, Mr. D. C. Jackling, one of the great captains of our mining industry. That was a turning point in his career, and it was only eight years ago, yet since then Mr. Bruce has achieved a notable professional success as manager of the Butte & Superior. Of course, the introduction to Mr. Jackling and the offer that followed was one of the opportunities that make a man's career. The point is that Mr. Bruce was ready for the opportunity, and was quick to recognize it at its real significance. Our readers will be pleased with his unequivocal answers to our questions, particularly in regard to apex litigation, Minerals Separation, labor troubles, and other matters of a delicate nature.

Mr. Bruce denies the pleasant story, often repeated, that the cost and annoyance of mining litigation at Butte has been much more than compensated by the large ore-bodies discovered in consequence of work done underground for the purpose of obtaining evidence for use in the courts. He gives a clear—and, we believe, fair—explanation of the cause of labor unrest at Butte, where the usual issue between capital and labor has been confused greatly by the rivalries and squabbles of opposing parties within the ranks of labor, this confusion being caused chiefly by the radical and irresponsible element typified by the I. W. W. Of the so-called welfare work he approves, and more particularly the current prac-

tice of giving employees some regular means of representation, whereby their just grievances and desires can be brought before the management; but he recognizes, as others experienced in such matters have done, that the mere bigness of the modern industrial enterprise, in mining as in other branches of organized human effort, tends to separate the employee from direct contact with his employer and thereby to spoil the human relationship on which effective leadership and successful co-operation may depend. Another change prejudicial to a mutual understanding between manager and men is the withdrawal of many of the native-born from mining, especially from work underground, and a proportionate increase in the foreign element. In some mines this involves the difficulty of speech, for many of the aliens do not speak English, and under such conditions it is doubly difficult to create anything like a good understanding with the working force. To cure this the night-school and the Y. M. C. A. must be supported and developed. Mr. Bruce speaks wisely, we think, on the subject of young college graduates undergoing the hard experience of manual labor in the mine with a view to qualifying as bosses. What he says needs no interpretation; nor does his sensible suggestion that our technicians should take a larger interest in civic and national affairs, in short, that they should realize their privileges as citizens. Undoubtedly Theodore Roosevelt ten years ago and Mr. Herbert Hoover today have quickened this impulse among the young men. Mr. Bruce himself, we happen to know, is a director of the Chamber of Commerce in his own city, so he appears to follow the advice he gives to others. That is characteristic; he is sincere. He is a man who does not waste words. Quiet and unassuming in manner, he suggests reserve power. As a young fellow he acquired unusual skill in surveying and mapping; that gave him his start; later he developed a keen sense of practical economies and thereby became a highly successful mine manager. He keeps closely in touch with everything that is going on; he is not a man of a dependent nature; he is progressive, and always on the look-out for any improvement in method or machinery; he is not prone to snap judgments, but looks before he leaps. The change from a big company like the Butte & Superior to a small affair like the Davis-Daly was a serious step for him to take, as he explains in the interview; he took it because he is enterprising and was willing to incur reasonable chances. That is the true spirit of mining adventure. He has shown his restraint in adapting the equipment of the smaller mine to the exigencies of finance; in short, he is a manager, not a mere speculator. One who knows him well says that he has a way of getting things done, and the ability to inspire co-operation. That he is loyal himself is suggested by his appreciation of loyalty in others. He realizes that to play a lone hand is a poor game; in short, he is a born leader of men. He is still much too young to be looking backward, he has a future in which at least as much can be done as in the twenty years of his past active and responsible work. We wish him continued success.

THE BUTTE & SUPERIOR MINE, AT BUTTE, MONTANA

James L. Bruce, of Butte

An Interview, by T. A. Rickard

Mr. Bruce, you are of Scottish origin?

Of Anglo-Scottish. The family home during my father's time was first at Shaw Farm in St. Quivox parish, and afterward at Rokeby House, near Prestwick, in Ayrshire, Scotland. My mother was born in Ireland, her father, William Latimer, being of purely English, and her mother of purely Scottish, origin. My two sisters, my brother, and I were born in Dublin, Ireland.

When?

I was born on March 20, 1880.

What sort of an early education did you have?

I attended kindergarten in London, England, for maybe a year or a year and a half.

How did you happen to go to London when your home was in Dublin?

My father met with reverses of fortune during the panic of 1883 in Ireland and left for Ontario, Canada, to make a new home, during which time our family, with my mother, went to live with my mother's mother in London.

What further education did you have?

As a matter of fact, I had very little. Our family settled for a time on a farm near Haliburton, in Ontario, Canada, at a place without school facilities, so that the family's early education was confined to the home. My mother and an aunt from Scotland, who came to visit us

for a time during my mother's illness, were our teachers. Later, when I was about nine years old, my mother having returned to my grandmother in London on account of very poor health, our home was made with cousins near Woodstock, in Ontario, where I went to a country school distant about a mile and a half from the farm upon which we were then living. I attended this school for about four years, after which my brother and I joined my father at Denver, in the fall of 1893.

What was your father's occupation?

My father spent many years, prior to the date of my birth, in Ireland, where he was engaged in the nursery, seed, seed-implement, and fertilizer business. He traveled through Ireland as a commission agent, handling the above and related mercantile lines, during a portion of this period. By the way, he was the inventor and patentee of special machinery used in the separation from each other of different species of grass seeds and in the elimination at the same time of weed seeds, machines of this make being supplied to several foreign countries, including France, Italy, Germany, and Austria.

So that is where you got your feeling for engineering?

I presume this is to some extent responsible. All my paternal ancestors on the Bruce side, as far back as my great-great-great-grandfather (1719), were Scottish estate-factors, and as such were necessarily engaged more

or less in land-surveying, building of farm-steadings, road-making, and such work, but not one of them was a trained engineer in the modern sense. William Murdock, the inventor of gas-lighting and of several improvements to the steam-engine, was a member of our family, although I do not know the exact relationship. He was also, I believe, the first to install steam-engines in connection with mining, at Redruth, Cornwall, and was a partner of Boulton & Watt, of which firm James Watt was the inventor of the steam-engine. My maternal grandfather, William Latimer, an Englishman, was a civil engineer and was killed by a fall from his horse while engaged in building the first line of railway from Dublin to Belfast. His father-in-law, Thomas Millie, was also a civil engineer and died at Brockville, in Canada, while assisting in the construction of the Grand Trunk railway.

What took your father to Denver?

My father, soon after my mother's departure for London, removed to Florida, engaging for a time in the brick-making and mercantile business, and later went to Denver, where he established a business, which was transferred to Cripple Creek immediately after the great fire which destroyed that place in 1896.

Well, I can see that you were getting nearer the mines.

Although originally my father's business and not the mines had brought me to Colorado. While in Denver I attended the grade schools, and owing to unfamiliarity with United States history and other courses, it was necessary for me to start in the sixth grade. My advancement, however, due to my Canadian school training, was fairly rapid, and despite irregular attendance I was able, after going to school in Denver for a little more than two years, through the assistance of my brother, who had had more schooling, to prepare for entrance to the Colorado School of Mines, examinations for which I was successful in passing in 1896.

Your brother had preceded you at the Colorado School of Mines?

Yes. He had completed most of his high-school course and had finished one year at the School of Mines at the time of my entrance.

What is your brother's name?

Stuart S. Bruce. He is now at Victoria, B. C.

So you graduated from the Colorado School of Mines, Mr. Bruce?

Yes, I graduated in 1901, after having attended for the freshman and sophomore years, and thereafter remaining out for one year, during which time I assisted my father in his grocery business at Cripple Creek, to which he had removed from Denver a year previously.

So now you were actually among the mines.

Yes.

What are your first impressions of the mines? Were these the first mines that you had seen?

I had seen some of the coal and clay mines in the

neighborhood of Golden before going to Cripple Creek, but had no familiarity or experience with metal mining, and, as a matter of fact, my intention when I first went to Golden was to take the electrical engineering course, which was also included in the curriculum at that time, but coming in contact with mining people from various parts of the State and from other places created an interest in the mining industry which lead me to take the mining course, this determination being made toward the end of my freshman year.

Why did you discontinue your work at Golden?

After having completed the sophomore year I found that my finances were insufficient to see me through the complete course and I found it necessary to go to work for a year and raise the necessary funds.

How did you do it?

I joined my father at Cripple Creek, taking up as much work as I could secure along my professional line, in assisting the mine surveyors and engineers of the district.

With whom did you work?

My first employment was with E. P. Arthur, in making the location of a mining claim called the 'Neversweat'.

That seems to be ominous of Butte.

Yes, and I might add that the Neversweat claim was located on one of the hottest days ever seen in the Cripple Creek district. I also assisted Haff & Colwell, and, if I recall correctly, probably assisted, on one or two occasions, the firm of Hills & Willis, who were among the first engineers in the Cripple Creek district. I feel grateful to the members of the profession in Cripple Creek who gave me this first opportunity to get a start.

Then you went back to Golden and completed your course in 1901. After graduation where did you go?

My brother in the meantime had been employed by the Arkansas Valley smelter at Leadville as an engineer and through his good offices my first position was secured with Charlie Taylor, who had the contract for doing the assaying for the Ibez Mining Company.

The Ibez Mining Company operated the Little Johnny mine, did it not?

Yes, and this mine was one of the important producers of the Leadville district at that time. Mr. Taylor had the contract for all their work, at a flat price of \$1000 per month, and through some development of friction in the organization, the shift-bosses and foremen were trying to overload the assay-office with samples. It is probably of interest to inform you that during one month we made more than 24,000 determinations for gold, silver, lead, zinc, manganese, copper, and silica, at an expense to the mining company of \$1000.

How many of you were there in the assay-office?

There were, altogether, including the men who prepared the samples, seven men.

How long did this contract remain in operation?

Until after my departure; but the tremendous number of determinations gradually decreased in the four

How much did it cost you to live?

Probably about \$50 per month for the necessities. I had no rent to pay.

CRIPPLE CREEK, COLORADO, IN 1900

or five months during which I was employed there, to about 15,000 determinations—not samples.

How many determinations were made per sample?

Well; sometimes one, sometimes two, sometimes five or

Why did you quit?

In the fall of 1901 I had an invitation to take a position that seemed to offer better opportunities, with the firm of Hills & Willis in Cripple Creek, as drafts-

THE AJAX MINE AT CRIPPLE CREEK

six. The average number of determinations per sample was probably about three.

What were you paid?

My average earning per month was between \$80 and \$85.

man and assistant to the surveyors and engineers, at a salary of \$100 per month.

This gave you a good opportunity of becoming acquainted with the geology of the Cripple Creek district?

Yes; while I was principally occupied in drafting and

platting of survey-maps, there were many occasions on which I was taken into the field, when I had an opportunity to gain experience in the practice of mining and in the operation of the mines and the geological side of the profession. I also had quite a little experience in the preparation of exhibits and assisting with examinations preparatory to apex litigation.

Do you not think that the surveying department is a good ante-room for a young mining engineer?

I think it is, provided the engineer doesn't develop, as frequently happens, a sense of satisfaction with this comparatively independent position, which will cause him to avoid the operating and clerical departments, thus depriving him of much of the experience that would equip him with qualifications for an executive position.

How long did you remain at Cripple Creek? Were you there during the big strike of 1903, and can you say anything about it?

I was assisting Mr. Hills in an examination of the Dead Pine mine, which connected with the Gold Coin workings, and we were engaged in that work at the time an explosive trap was discovered on one of the stations of the Gold Coin shaft. The railroad station at Independence had been dynamited, the militia had been ordered to the district, and a semblance of order had been established. The Gold Coin organization had discovered a box of explosives that had been arranged to cause a wreck of the shaft and station by a trigger so set as to be operated by the passing of the cages. The discovery of this probably brought about the more effective guarding of the properties of the various companies. Additional militia were ordered to the scene of trouble. I remember well that one or more machine-guns were trained by the militia on the approaches to the building in which our offices were located in Cripple Creek, as a protection to the Court in session in the same building, which was opposite the National Hotel.

What view do you take now in regard to that particular industrial trouble?

As I recall it, this was a strike that was called for the sole purpose of expressing sympathy with certain strikers at the mills of Colorado City, and I think that there was no grievance with the conditions at Cripple Creek itself, and as various acts of violence had taken place it seems to me that it was essential that peace be restored by armed force. One of the factors in the situation was the bellicose attitude of Sherman Bell, who commanded the militia. He seemed to be devoid of any sense of tact, and provoked unnecessary ill feeling by his truculent behavior. The ultimate outcome, however, was a co-operation of the mining companies in an employment agency, which probably brought about a more generally satisfactory contact between the employers and the employees than had previously existed.

Would that include the black-listing of the unruly or the anarchistic?

As to that I cannot say.

How long did you remain at Cripple Creek?

I left the Cripple Creek district in April 1904, in order to take a position with the Federal Lead Company in south-eastern Missouri. This enterprise was then under the general management of J. R. Finlay, with whom I had previously become acquainted when he was general manager for the Portland Gold Mining Co. at Victor, in the Cripple Creek district. I had assisted Mr. Hills in preparing his portion of the annual reports of the Portland and had also given special assistance to F. L. Ransome and Waldemar Lindgren in the report that they made on the Cripple Creek district for the U. S. Geological Survey, and no doubt was suggested for the position by Alfred Roek, with whom I had become friendly while he was employed by the Survey at Cripple Creek, and who had accepted a position with the Federal Lead Company before I went there. I also became a friend of L. C. Graton, who was assisting Ransome and Lindgren. I recall with pleasure the many good friends I made at Cripple Creek.

While at Cripple Creek did you go to any other mining centres?

I accompanied Mr. Hills as his assistant on an examination that he made of the Lustre mine at Magistral, near Inde, in Durango, Mexico. Inasmuch as this mine was about a hundred miles from the railroad terminus at Rosario and in a community of about 1200 people, with only 10 English-speaking people, it proved to be of unusual interest. The property was owned principally by Pittsburgh people and was under the management of Walter Koeh, a delightful gentleman, who made the occasion a pleasant one in spite of the discomforts of a hot climate and an existence without such commonplaces as milk, butter, or eggs. A peculiarity of the property was that the ore was self-fluxing, and of a pyritic character, so that by semi-pyritic smelting there was produced a copper matte, which was shipped to the American Smelting & Refining smelter at Aguascalientes for further treatment.

So then you went to Missouri?

Yes. I accepted a position as engineer for the Federal Lead Company, although the compensation was considerably less than I had been earning at Cripple Creek.

How much?

I was earning \$150 per month, and accepted the new position at \$100 per month, as I was especially desirous of coming into more direct contact with the actual conduct of operations than my opportunities as a surveyor afforded with the engineering firm at Cripple Creek. I was an admirer of Mr. Finlay's capability as a mining administrator and was very glad to have the opportunity of working with him.

What was the nature of the mining operations?

At that time the scale of operations of the Federal Lead Company was not a large one and the property had not been developed to the point of profitable or large production. The ore deposits consisted of galena dis-

UNDERGROUND IN THE CONTINENTAL MINE, AT JOPLIN

THE CONTINENTAL MINE, AT JOPLIN, MISSOURI

seminated through limestone at depths ranging from 200 to 500 ft. The ores were concentrated on jigs and tables, the concentrate being shipped and treated at a smelter near St. Louis.

Did you remain long at Flat River?

I remained there until March 1907, first in the capacity of engineer and after six or eight months as general mine-foreman, a position that brought me into intimate contact with the mining and milling operations. Mr. Finlay left a few months after my arrival and the management devolved upon T. F. M. Fitzgerald. During my employment as general foreman the properties of the Central Lead Company were purchased by the Federal Lead Company and a comprehensive program of new development and construction was undertaken, including the erection of a new concentrating plant. I was appointed chief engineer and co-operated in the erection of the new plant. I may mention that prior to this I was in charge, for a few months, of the diamond-drilling exploration of the company and so obtained a knowledge of that form of prospecting. It is interesting to recall that the mine shift-bosses at that time earned \$2.40 per day, miners \$1.90, pumpmen \$1.60, machinists and blacksmiths \$2 to \$2.25, jigmen \$1.75, mill-helpers \$1.50, and surface laborers \$1.30. The mill employees worked eight hours, and I believe the others worked ten hours per shift.

So your stay at Flat River was useful to you in enlarging your experience?

Yes, and also in increasing my friends among members of the profession. H. G. Washburn, who is now manager, came there at my invitation, as locating engineer for the Lead Belt Railway, which is owned by the Federal Lead Company and which at that time was being extended under my direction as Chief Engineer. This railway is one of about fifteen or twenty miles trackage; it serves to transport ore and supplies between the mines and mills and the Mississippi River & Bonne Terre Railway. L. G. Johnson, who at that time was my first Assistant, is also still in a responsible position with the Federal Lead Company. Tom Hackwood, who was Mill Superintendent at the time I went there, later became Assistant Mill-Superintendent at the Butte & Superior during my management. His son, Arthur, who as a boy helped me with the surveying at the Federal, completed the mining course at Rolla and became Chief Research Engineer at the Butte & Superior. W. S. Grether, who was also employed in the engineering department of the Federal Lead Company, after various experiences in other fields, again joined my forces at the Butte & Superior, and after taking charge of two or three outside operations for the company, now occupies the position of Assistant Mine-Superintendent. I greatly appreciate the loyal and capable support given me by all these friends.

While at the Federal it was my pleasure to establish a friendship with T. F. M. Fitzgerald, Corey C. Brayton, Frank Estes, H. A. Guess, C. V. Jenkins, Henry Krumpholtz,

E. G. Godshalk, H. A. Buehler, Allen H. Rogers, E. T. Stannard, and many others of the profession, the benefit of whose experience I have had on many occasions.

When did you leave Flat River?

In the spring of 1907. Upon Mr. Kirby's taking the management of the property I was not afforded the opportunity that I desired of again resuming a responsible place in the operating department. As I was offered a position about that time as assistant superintendent of the Grace Zinc Company, in the Joplin district, of which Mr. Finlay was President and General Manager, I decided to accept it and went to Joplin in March 1907. I remained as assistant to W. H. Gross, the superintendent of the Grace Zinc Company, for a little more than a year, and in November 1908, the property being nearly exhausted, I accepted a position as manager of the Nortonia Mining Company, also at Joplin. This connection, however, being unsatisfactory—

Why was it unsatisfactory?

On account of the failure of the officers to provide funds to pay the crew.

You are excused. I have known what that means.

As a matter of fact, the property was in debt when I took charge of it. Shortly after starting up, the bank deposits were garnished by creditors, and upon the officers of the company failing to provide funds for payment of the employees, I produced sufficient concentrate to pay the men and, after shutting-down the property, resigned.

Did you remain at Joplin?

Yes. Fortunately, within a few days thereafter I was invited to Boston for an interview with the officials of the Continental Zinc Company, who were then in need of a manager. Fred Jordan, the previous manager, having resigned to take a position in Canada. He is now with the Mesabi Iron Company and was at that time a good friend of mine, and in fact recommended me as his successor at Joplin.

Who controlled the Continental Zinc Company?

At that time it was controlled jointly by the firms of Ladenburg, Thallman & Company and Hayden, Stone & Company.

So this time you had good backers?

Yes, indeed. I think that this was the first mining venture of the Hayden-Stone organization, and for that reason they have always taken an interest in the property, which its size would not otherwise probably have justified.

What kind of ore deposits were they exploiting?

Their properties were producers of zinc and lead, occurring, in the case of the Litteral mine, as the well-known sheet-ground deposit of sphalerite and galena in chert layers within the limestone, at a depth of approximately 200 ft. By the way, we had some very low mining costs in connection with this property. In the face of difficulties encountered in pumping a strongly acid

water, and unusual milling expenses due to its destructive action on all metal work, our costs of mining and milling, including all general expenses, for a year's operations, in 1912, were a little less than 85 cents per ton.

What was the grade of the concentrates?

The lead concentrate averaged a little more than 80% lead, and the zinc concentrate about 57½% zinc.

Your production was concentrates? You did not treat either of the two concentrates yourselves?

No, this was sold to custom buyers, as is usual in the Joplin district.

Did you remain long with the Continental?

I was in charge of the Continental operations until March 1913. On February 1, I was given leave of absence to assist Mr. Finlay in a comprehensive examination that he was making of the properties of the St. Joseph Lead Company in the Flat River district, with which I had become familiar during my prior experience, and while so engaged was invited to a conference with D. C. Jackling, who was then developing the Butte & Superior property in Montana. I met Mr. Jackling and traveled with him in his private car from Kansas City to Topeka, and during the journey he suggested that I make a visit to Butte with a view to considering the management of the Butte & Superior.

What were your impressions of Mr. Jackling when you first met him?

I discovered very soon that he was thoroughly familiar with the technique of mining and in all respects a man of unusual capability. It appealed to me very much also to be afforded an opportunity to work for a man who would so thoroughly appreciate not only the accomplishments but the difficulties of the management of a mining property, and I had no hesitation, as soon as I learned that Mr. Finlay could release me without embarrassment, in coming to Butte to review the situation. This I did at the earliest opportunity, arriving in Butte some time during the latter part of February 1913, spending a few days at the mine and mill, after which I returned to make arrangements for my successor at the Continental Zinc, and to move my family to Butte.

When were you married?

I married Miss Mary Louise Temple, of Joplin, on June 16, 1909, and had the very sad experience of losing her on our fourth wedding anniversary, shortly after coming to Butte. On December 25, 1915, I married Miss Leah Sidney Hills, the daughter of my former chief, Victor G. Hills, of Cripple Creek. We have four children, two girls and two boys.

So you took charge of the Butte & Superior just about the time the flotation troubles began?

Yes. Shortly after the filing of the suit, which occurred in 1912. Mr. Hyde was still conducting experimental work at the Butte & Superior mill, but left shortly after my arrival.

Mr. Bruce, you had a great deal of experience in mining litigation of one kind or another, and the lawsuits both with the Minerals Separation company and the Clark estate must have added a great deal to your anxieties as manager of the Butte & Superior?

Yes, these controversies occupied a great deal of my time and attention and occasioned a lot of traveling and my attendance in each of the Federal courts.

Do you look upon these litigations as unnecessary evils?

That is, do you think that either the apex suits or the flotation suits could be avoided if the laws were revised?

I think that the revision of the apex laws could be beneficial only to future mining locations, inasmuch as they could not be made retroactive, but I think nearly all of our profession are agreed that some modification of the laws should be effected for the benefit of future locators and their assigns. The advantages or encouragements afforded by the law seem to be very much more than offset by the uncertainties and tribulations arising from its interpretation. With respect to the patent laws, it seems to me that while it is certainly desirable to encourage invention through patent protection, there should be some limitation not now afforded by the law from monopolies that may be created thereby.

Do you think it is possible to effect a settlement with the Minerals Separation people so as to relieve the mining industry of the incubus of their harassment?

It seems to me that the situation has become so complicated and the disposition of the Minerals Separation Company to exact punitive penalties from alleged infringers so stubborn that there is little probability of a settlement. The difficulty of securing a satisfactory co-operation of the mining operators is also a serious obstacle. It really looks very much like an almost endless campaign of litigation, unless the royalties demanded by the Minerals Separation people are reduced to such a figure as will induce the mining industry to pay them on those processes on which they claim patent protection.

You suggest that the M. S. people might become more reasonable—that is, that they might become so reasonable as to cause mine operators to accept their royalties without further antagonism? Do you think this is likely?

My view is that further litigation will establish the weakness of their position, which will ultimately provide the industry with clear-cut methods of escape by means of non-infringing processes.

I think there is a good deal in what you say. Some of their basic patents will shortly be expiring and meanwhile the continued research is leading to the discovery of methods for avoiding even the alleged infringement of their patents.

I believe that the process used today at Ray, known as the oiled-air process, is not an infringement of the

M. S. patents. I think that this, with other known processes of highly efficient character, will not be found by the Courts to infringe.

It has been stated in print that the mining litigation at Butte has led to the discovery of important ore-bodies; indeed, that the discoveries have involved so large a tonnage of ore as to pay for the cost of the many litigations, but while I have been in Butte I have been told, by Professor Clapp of the School of Mines, for example, that this is not so, and that the amount of ore discovered does not begin to compensate for the money wasted in litigations. What is your view of this?

I think it is doubtful whether the discoveries of ore as a result of development litigation have repaid the cost of such development work. There may be a near approach to it in some cases, but I think it is certainly true that the entire cost of litigation has only in rare cases been re-paid by the discovery of ore. In the case of the Butte & Superior litigation there was probably very little ore developed that would not have been opened up in the regular course of events, so that the cost of litigation, to both parties, amounting to probably not less than a million dollars, was practically uncompensated.

While you were in charge of the Butte & Superior you had labor trouble of a serious character in Butte, affecting your own management, I suppose. Would you please state the origin of these troubles, and what you consider the best means of preventing their recurrence?

The labor troubles in Butte have been occasioned, in most instances, by jurisdictional disputes between unions, or by the agitation fomented by outside organizations. They have seldom arisen from disputes between employer and employees. The first troubles with which I am familiar in the Butte district arose in 1914 from mismanagement of the local officials of the Western Federation of Miners, which brought about dissatisfaction of the union members with their own organization and resulted in its being broken up by spontaneous opposition of the rank and file. Advantage was taken of this situation by the organizers of the I. W. W. and the other extremists to secure control of the unorganized opposition to the Western Federation. The maintenance of this control during the period of the War, due to lack of labor and high wages and lack of effective law enforcement, was easy.

But why should a squabble in the ranks of the union cause the men to strike, that is, to quit work?

Most of the strikes in this district have been brought about by intimidation of employees, who have not been afforded sufficient protection, and who have a natural reluctance to continue at work in the face of threats and abuses directed not only against them personally but against their families, because they do not align themselves with the malcontents.

Your explanation applies to the strike of 1914, but how about the more ugly troubles of 1917?

The same statement applies to that. This strike was fomented by an electrician by the name of Dunn, who, it is presumed, had financial support from the headquarters of the non-partisan league or the I. W. W., and this probably instigated by pro-German propagandists. The finances supplied him were sufficient to enable him to establish a newspaper in the district, which secured the support of all the radical element. Dunn, for a time, was successful in securing a large following and in organizing a gang that was efficient in conducting sabotage, and, after the strike-call, intimidating the great majority of the miners and craftsmen, who would have been satisfied with conditions if permitted to continue their employment undisturbed.

Was the alleged cause of this strike a quarrel between unions, or did it arise from complaints as to the manner of employment?

The principal demands of the striking miners included the recognition of the Metal Mine Workers' Union, known with certainty to be under the domination of the I. W. W. organization, demand for higher wages, abolishment of rustling cards, etc.; but inasmuch as the strike was called shortly after the declaration of war by the U. S. and about the time of the draft calls, it seems clear that it was undertaken in response to systematically organized propaganda to obstruct the preparations of the War Department. A scarcity of labor and an expansion of industrial activities, of course, brought a ready response to any demand for higher wages or shorter hours. Shortly after the call of the miners' strike, sympathetic strikes were called by the electricians, machinists, boilermakers, and blacksmiths. The Metal Mine Workers' Union was not, however, recognized by the operators, and practically all employees had returned to work within a month after the date of the strike call.

What further strikes of importance have been called?

On April 18, 1920, a strike was called by the local No. 8 of the I. W. W. The demands made at that time, however, were very clear evidence of the fact that the strike was not called with the expectation of reaching any agreement that would better the conditions of employees. Demands called for a minimum wage-scale of \$7 per day for six hours work, and the release of all industrial and political prisoners, and other features which manifestly were not within the power of the mining companies to meet. No doubt the I. W. W. organization at that time considered that there was a reasonably good chance throughout the United States of creating sufficient discontent to cause the initiation of revolutionary acts.

Do you think that the relations between managers and men at mines have improved or otherwise during your personal experience in the West?

I think they have improved. Of course, the tendency

of the growth of larger corporations has been to separate the employees from as direct contact with the management as they used to have in the earlier days, but within the past few years there has been a much better consideration given to the welfare of employees, improvement of their working and living conditions, provision

for their representation, and the hearing of their grievances and suggestions. Nearly all of the larger companies, where the management does not come in direct contact with the employees, have well-recognized means of giving them representation.

Have you noticed a difference in the composition of the working forces in regard to changes of nationality or race?

Since I came here in 1913 there have been appreciable changes in the relative numbers employed of different nationalities and in the average ages of employees. Most of these changes are such as would naturally have been expected as a result of the War. In March 1913, of all employees in the Butte mines, approximately 35% were native-born and 65% foreign-born, as compared with 33% native-born and 67% foreign-born in the fall of the year 1918. In 1913 the percentage of foreign-born employees who had become naturalized was about 54%, as compared with only 37% in the fall of 1918. The proportion of employees in 1913 under 30 years of age was about 40%, as compared with a little less than 30% in 1918. In 1913, of the total number of foreign-born, about 65% came from English-speaking countries, while in 1918 there were only about 45%, the decrease being no doubt due largely to the demands of the War. Aside from the English-speaking workers, the principal foreign-born employees come from Austria-Hungary, Finland, Italy, and Sweden, with a scattering from almost every other European country.

What opinion do you hold as to the advisability of college graduates working up from the ranks, that is, engaging in manual labor underground, becoming foremen, and so advancing to positions of greater responsibility? Do you think that it is well for college graduates to go through this experience? Is it good for them, and is it good for the industry?

That depends entirely upon the individual. Some

THE DAVIS-DALY SHAFT

THE DAVIS-DALY MINE AND THE TOWN OF BUTTE

college graduates are so constituted, physically and mentally, that they pursue this course with credit to themselves and with benefit to the mining industry, arriving at positions of responsibility. Very many, however, are not so constituted as to survive the physical hardships of such a course without detriment to their mental progress, and I would not at all generally recommend this program. I think that a modest amount of underground practical experience would be of benefit to the majority of technically trained engineers, but in my experience the chief omission in their education is in business training, rather than in practical experience. I believe that contact with business men of experience and with business conditions can best be brought about in general by encouraging the graduate engineer to take a serious interest in matters of public and civic character.

Do you think that they ought to learn something of accounting, book-keeping, and economics, rather than thump a drill?

I think that this would usually benefit them more.

So you think, Mr. Bruce, that our young engineers should show a greater interest in civic and national affairs?

Yes, I certainly do. I think that they need more contact with men of experience in business methods and the advantages of the second-hand experience that would be gained by such contact. This can best be acquired by active interest and attendance at the meetings of organizations of a civic or business character, such as Chambers of Commerce, School Boards, Y. M. C. A.—in fact, any well-organized institution that performs its functions in a systematic or parliamentary manner.

Returning to your own career: How long did you remain with the Butte & Superior as General Manager?

Until January 1, 1920. In the middle of September 1919, I accepted the management of the Davis-Daly Copper Company, and acted as manager for both properties until the end of the year, at which time my resignation as manager of the Butte & Superior became effective.

Why did you resign?

There were several reasons: In the first place, I had an opportunity to take the management of the Davis-Daly at an attractive remuneration, and, in the second place, I was desirous of obtaining new experience in the copper industry, after having spent some years in the mining of lead and zinc ores. Furthermore, the amount of my attention that had been required by the comprehensive litigation of the Butte & Superior had become distasteful, and, while my associations and responsibilities as manager of the Butte & Superior had at all times been extremely pleasant, the new opportunity appeared to offer a chance for experience in a fresh direction.

I am glad to hear that you think you can escape litigation anywhere in the Butte district!

Well, I don't think that can be assured!

While you were with the Butte & Superior you examined a good many mines in various districts, did you not, for that company?

Yes, I made a number of examinations, and some of the properties were taken over and operated for a time. Among those operated were the Hudson Bay Zinc Co., near Salmo, B. C.; the Metalline Falls Zinc Co., near Metalline, Washington; and a large group of leases and options directly north-east of the Picher Lead Company's holdings in the Miami district of Oklahoma. I also examined the Interstate-Callahan, the Success, and the Black Horse properties near Wallace, Idaho; a zinc property in Inyo county, California; copper prospects on Valdez island, B. C.; and a number of properties in Montana. I also acted for a time as consulting engineer to the American Zinc, Lead & Smelting Co., and made examinations of their properties in the Joplin and Granby districts, Missouri, and at Mascot, Tennessee. At this time I became well acquainted with H. R. Kimball, J. N. Houser, H. I. Young, W. F. Rossman, and W. G. Swart, who have been my good friends and counselors since.

Do you believe it to be a wise thing to perpetuate the organization of a mining company by the acquirement of new property, and also for a company to spread its activities so as to average its risks?

Yes. Any well-organized mining company is in a position to utilize its existing organization with comparatively small additional expense as compared with a new organization, and with much better efficiency, in taking up new properties that may show promise. As to the spreading of risks, although it is worthy of consideration, it doesn't appeal to me so strongly, as I feel that the individual stockholder, unless altogether uninformed as to the character of his investments, can spread his own risks by investments in the stocks of various non-attached mining companies.

Is the Davis-Daly Copper Company an old enterprise?

As a producer of consequence it has existed only since 1915, but following its date of organization, in 1907, an active program of exploration and development work was conducted. The principal orebodies, however, were not discovered until considerable depth had been reached.

How deep?

The first really important discovery was made at about 2500 ft. This ore has been followed to higher levels and has been the chief source of production since its discovery. Little development below this depth has been done, and the deepest development of ore at this time is on the 2700-ft. level, the shaft being 2850 ft. deep. The 2700 level, however, is equivalent to a depth of nearly 3200 ft. in some of the shafts situated on higher ground.

Do you think that the difference in elevation affects the nature of the ore deposits?

I think that the ore deposition in the deeper levels of the Butte mines is not affected by the surface contour.

I come to this conclusion from the fact that the oxidized surface ores persist to less depth at the lower surface than at the higher, and observations seem to show that the rock temperatures are about the same at the same horizons irrespective of surface elevations.

You have a cheerful feeling as to the future of mining in Butte, despite the present depression?

Yes, I can see no reason why the orebodies should not be mined as deeply as is possible within the limits of economy. Of course, as the temperature increases and ventilation becomes more difficult and hoisting more expensive, richer ores will be required to meet the cost.

What is the depth of the deepest workings, and what is the temperature at that depth?

The deepest shaft is the Steward, of the Anaconda Copper Mining Co., which is now 3633 ft. below its own collar and 3838 ft. below the collar of the High Ore shaft, with which it is connected. The deepest ore developed is about 75 ft. above the bottom of the Steward shaft and at an elevation of 2354 ft. above sea-level. In the deeper levels of the Butte mines when they are first opened the rock temperature is about 103° to 104°, and in some cases up to 110°F. Some rock temperatures in the district are considerably higher than this, but only in the vicinity of underground fires.

The persistence of ore in the Butte district has been remarkable. You consider the prospects are still good for further persistence? Of course, by ore I do not mean vein-matter, but mineral that can be exploited at a profit.

Yes; I know of no district in which there is greater probability of continuance downward of the orebodies. Of course, not all ore-shoots have continued to go downward, but the number and importance of ore-shoots at the greater depth does not seem to diminish.

You have done some interesting work at the Davis-Daly, as I happen to know. Would you say something about your octagonal shaft?

We have just completed a unique shaft, exclusively for ventilation. This was raised from existing underground levels of the Colorado mine from a depth of 1800 ft., and the work, including about 600 ft. of cross-cutting, was completed in a little more than five months, at a cost of about \$71,000.

Is this shaft brick-lined?

When considering the ventilation, the proposal was made to construct a circular concrete-lined shaft, so as to give the least area of resistance to the air, relative to the area of the cross-section. This, however, was considered impracticable, from the standpoint of time and expense. A substitute was devised, however, and an octagonal cross-section was adopted, with timber brick-ing constituting the sides of the octagon.

What do you mean by "timber bricking"?

The lining was constructed of blocks of wood approximately 8 in. wide by 10 in. deep by 3 ft. long, with a

specially devised framing to fit the ends together in a proper manner to support the pressure, giving a smooth-lined, timber-cribbed, or bricked shaft, free from posts or lagging.

What is the diameter of the shaft?

The minimum inside diameter of the octagon is 6½ ft. This has an area of 34½ sq. ft., and gives approximately the same air-capacity as a smooth-lined two-compartment shaft with an area of 45 sq. ft. in the clear. The amount of timber, however, that would have been required for the two-compartment rectangular shaft would have been 72% greater, and the amount of excavation 50% greater than with the octagonal shaft. The cost of timber used in the main section of the shaft, at a price of \$37 per M, including all temporary timber and the cost of framing, amounted to only \$11 per foot, which is less than the cost of timber for the regular 5-ft. sets in a standard two-compartment shaft, using 12 by 12-in. wall-plates and end-plates.

How much less?

About 80 cents per foot of shaft.

Would you tell me something about your sorting-plant?

There is nothing very unusual about that. The skips of ore are hoisted and dumped into a small hopper, feeding directly into a mechanical grizzly of the Sheridan type, which is constructed of bars, the alternate members of which are operated by two sets of eccentrics, one set of bars raising the coarse ore, carrying it forward and depositing it on the other set of bars, which in turn repeats the performance, the fine passing through and the oversize being fed at a fairly uniform rate to a slow-moving belt-conveyor, with a speed of 30 ft. per minute, which acts in the double capacity of a distributing conveyor to the bins and a sorting-belt, from which the waste is removed by hand and the remainder of the ore separated into 'high-grade' and 'low-grade'. The ore as it is hoisted is classed as first-class or second-class and the fine of the one separated from that of the other by a swinging door placed beneath the grizzly. It has been found that the ore can be sorted at the rate of two skips, each containing 3½ tons, every five minutes, at a low cost and with good efficiency.

What is the low cost? That is, from mine to shipping-bin?

The cost per ton of ore hoisted is a little less than 8 cents, there being about 10% of waste removed, the remainder usually being divided into nearly equal quantities of first-class and second-class.

You have seen a good deal of improvement in safety precautions in the mines of Butte, and I presume that you have been glad to further this improvement?

Yes. At the Butte & Superior property our organization developed some protective features that were unique. One of these was the system of signaling to employees underground in the event of fires or dangerous gases.

by means of the introduction to the compressed-air lines of volatile substances such as valerianic acid, which would permeate the air in the underground workings with significant odors. I believe this was the first development of this practice. The idea originally suggested itself to me that the arteries of air-lines throughout the mines should be an almost ideal means of distributing signals, and we endeavored at first to develop some electrical warning, without, however, arriving at any satisfactory solution. I think it was my suggestion thereafter that an odor in the form of gas be introduced into the air, and the research department, under the direction of Arthur Hackwood, working on this idea, suggested the better plan of using essential oils or liquids, and discovered the good qualifications of valerianic acid. This is fed into the air-receiver on the surface with a gravity-feed lubricator.

Has the U. S. Bureau of Mines availed itself of this interesting information?

I understand that they have made some experiments and developed other suitable reagents. Another interesting development in connection with safety measures was the introduction of stations or chambers underground. At a small expense, short lengths of old cross-cuts or drifts were partitioned off, with a door in the partition, and compressed-air lines carried into such stations, and, when available, water-lines, so that men finding themselves about to be cut off by dangerous gases may take refuge in the stations and prevent the entry of such gases by closing the door, this being made airtight by calking with oakum, which is kept in the station. The exclusion of gases is further ensured by opening a valve in the compressed-air line, which furnishes the miners with fresh air and forces air from the station into the adjoining workings. When water-lines are not available, barrels of water are usually kept on a truck at the entrance to the stations. Such stations are marked with a sign or red light and are well known to all the employees.

Those are both interesting safety measures. Have you any others?

There were many others adopted. It was a rule of the organization that all shift-bosses must have taken training in the use of air-helmets and in first-aid. Water-pressure lines were installed down the shaft and in stations, and many other provisions made for the safety of men underground. The two first mentioned, however, are the only ones that are worthy of mention.

Do you consider mining today still affords a good career for young men?

Yes, I think that as the mining industry finds more difficult conditions to cope with, as it necessarily must, the demand for engineering ability will become greater and the status of the mining engineer will continue to improve.

During your management of the Butte & Superior you must have had an opportunity, partly owing to the

two big litigations, of becoming acquainted with a large number of professional men of high standing?

It was my pleasure to become acquainted with, as witnesses and counsel during these two lawsuits, many of the prominent and capable professional men of the day. Among the mining engineers there were J. W. Finch, D. W. Branton, Albert Burch, Walter H. Wiley, W. L. Creden, D. C. Bard, Sam Barker, Carl Hand, W. H. Emmons, R. D. Salisbury, witnesses for the Butte & Superior, and H. V. Winchell, Professor Kemp, Fred Searls, Professor Irving, Rush White, the late Fred Green, Professor Leith, witnesses for the Clark interests. It has always been a source of gratification to me to feel that my organizations both at the Butte & Superior and the Davis-Daly were constituted of as capable, as loyal, and as energetic a personnel as can be desired. I am under obligation to almost every one of them for the support and assistance given me. Especially do I appreciate the helpful assistance and friendship of Charles Bocking as assistant manager, who succeeded me as manager; Angus B. McLeod, the mine superintendent (both of whom occupied these positions during my entire term); and of F. T. Wicks, J. T. Shimmie, and E. V. Daveler, successive mill superintendents, as well as many others that I would like to mention by name were the list not so long. Among those now in the Davis-Daly organization are several who served with credit at the Butte & Superior, including J. W. Dudgeon, chief engineer and geologist; B. F. Evans, efficiency engineer; L. S. Farnham, mechanical engineer; and S. A. Worcester, mechanical foreman. These men, together with Dan McGrath, mine superintendent; Clint Hansen, geologist; R. H. Barelay, construction foreman; J. E. Murphy, auditor; and B. A. Tower, mine engineer, have earned much credit in the conduct of Davis-Daly affairs.

Have you any ideas in regard to the education of young men for a mining career?

I think the tendency of mining school of the day is to emphasize too greatly the value of experience gained in practical ways, in mining and metallurgy, during school years, and that more attention should be given to a thorough understanding of basic principles. A fair amount of contact with actual operations is desirable, chiefly for the reason that it stimulates keener interest, but the amount of experience that can be obtained during these years is so small, compared with what must be later undergone, that it is of little consequence if it means a sacrifice, as it frequently does, of a proper training in the fundamental subjects.

Zinc dust has been marketed by domestic smelters since 1910, states a U. S. Geological Survey bulletin. The United States Zinc Co., at Pueblo, Colorado, was the first to prepare it for the market; the Grasselli Chemical Co. followed later; and one by one other companies began to save zinc dust, until in 1918 eleven companies reported production, a part of which was made by subjecting a stream of molten zinc to a blast of air.

Valuation of Placer Deposits

By Gerald H. Hutton

The exploitation of placer ground by means of dredging has become an important industry. Rapid progress has been made in the development of a highly efficient machine for excavating the ground and recovering the precious metals; so remarkable has been the progress in mechanical improvements that it is possible, under favorable conditions, to dredge placer ground for 5½¢. per cubic yard in spite of high prices for supplies, power, and labor.

Improvements in methods of sampling and valuing dredging ground, however, have not kept pace with me-

chanical developments, and which perhaps will encourage general interest and action, will be described briefly; and in addition, there will be submitted, among other data, a method for placing drill-holes and computing cubic-yard value by graphic formulae. These systems were evolved from a study of comparisons between the results of drilling and actual dredging of ground under the control of the Metals Exploration Co. While they may not be accepted as conclusive or of general application, they may be of service in directing effort toward the improvement of present methods of sampling and perhaps may be tenta-

THE GOLD CANYON DREDGE NEAR VIRGINIA CITY, NEVADA

chanical developments. Standard methods of testing today produce only rough approximations of the value of the ground, although they obtain information concerning the character of the deposit and the bedrock. It is interesting to note that few important changes in the methods of ten years ago are to be recorded; on the contrary, the latest comparisons between sampling estimates and actual recoveries have varied so widely as to confuse the operator, and, in a degree, to shake the confidence of the capitalist. On this account, and because the growing scarcity of dredging ground demands closer and more accurate calculation, I desire to urge mining engineers and dredge operators to assist in formulating systems and methods that will tend to produce reliable results in testing placer deposits. Where an area has already been mined after having been sampled, a comparison of the results is invaluable for this purpose.

Some of the features which appear to warrant investi-

tively considered as a basis for the establishment of general principles for drilling.

DISCREPANCIES BETWEEN SAMPLING ESTIMATES AND ACTUAL RECOVERIES. As an example of these discrepancies: 15 cu. yd. has been mined to yield 4¢. per cubic yard from the range or scope of a drill-hole showing 45¢. per yard. In another instance, 100,000 cu. yd. dredged showed a recovery of 5½¢. per cubic yard, from the scope of one 12¢. and one 21¢. drill-hole. Again, 5,600,000 cu. yd. dredged 10.4¢. per cubic yard, whereas 16.5¢. was indicated by the drill-holes. On the other hand there are instances where the unit recovery has exceeded the estimated content by similar margins. In all these examples, there has been no reason to suspect 'outside salting' of samples or unusual inaccuracies of weighing or measurement, for standard drilling practice was followed.

DERIVING THE 'PROSPECT-FACTOR'. It is unnecessary

to describe present-day methods of sampling or apparatus for drilling. Suffice it to state that work performed by the Keystone drill with a 6-in. drive-pipe is here accepted as standard. Shaft-sinking cannot be efficiently conducted in wet ground. The purpose of drilling placer ground is to obtain systematically an accurate representative sample, which is utilized to derive a general average. It is important, therefore, that the sample be of sufficient volume to be representative and at the same time that it be taken with sufficient care to be accurate. Unfortunately, each deposit has its own characteristics, which means that more or fewer samples will be required to obtain a true representation. It will be evident then, that each deposit has its individual 'prospect-factor',

obviously is to increase, by systematic work, the probability of realizing the pre-determined recovery. Factors that will influence the continuation of this system of work will be, of course, the amount of money available for development, and the margin between determined recoverable gold content and the estimated cost of operation, since the desideratum of systematic sampling is primarily to justify investment. Modifications to the system should be made as required by special conditions; in this connection the geological history and conditions of the deposit will have important bearing.

METHODS OF MEASUREMENT USED. As stated above, in addition to the necessity for drilling ground sufficiently, it is equally important that the drilling be performed

which, in general terms, is the ratio of the volume of the drill-cores, or number of drill-openings that will afford a consistent representation to the number of cubic yards sampled. To derive the 'prospect-factor' of a piece of ground it is suggested as a general plan that drill-holes widely spaced be systematically spread over the area and the average value per cubic yard derived therefrom. These wide intervals may then be bisected with additional holes and the average value per cubic yard determined from the total number of tests. At the same time, the result of each separate group of holes may be carefully checked and compared. This method may progress until the determinations in the latest stages approximately agree; or, until it has been proved that the addition of drill-openings, systematically spaced, causes no important variation in the determinations. The intention

carefully and thoroughly so that data obtained may form a reliable basis for calculation. The personal element is of prime importance in drilling, particularly the experience and judgment of the engineer, driller, and panner; the work should proceed as far as possible with technical exactness. Measurements should be taken at every stage of the work and the logs designed in such a manner as to convey the most detailed information for the guidance of the engineer.

A method in common use is to measure the height of the core in the pipe before and after driving and pumping, and to measure the tailing from the rocker*; from these figures the engineer makes his adjustments and corrections. By one formula, 100 ft. of 6-in. drive-pipe is considered to represent one cubic yard of virgin

*An improved design of the old placer miner's device.

ground, and the value per cubic yard is thus simply obtained. Other methods involve the use of various arbitrary constants, based on the relation of pipe-content or core to 'bank-measure', a term applying to the volume of unmined ground.

An elaboration on these methods is suggested. The coarser material from each foot of 'drop' [or hole] may be measured in a box or calibrated bucket, and a record made of the ratio between the actual core extracted and the theoretical volume of core from this foot of drop. The slime or material in suspension in the water may be allowed to settle in a special box or pit for measurement. If the precious metals are obtained from a stratum whose 'core-ratio' varies from the average of those of the total number of holes drilled, then the results are subject to

GRAPHIC CHART OF 23 DRILL-HOLES SHOWING METHOD OF ELIMINATION

correction in proportion to that variation. Before using the core-ratio in the final computations, however, it is essential that the core-ratios be increased by allowance for the slime, by an amount depending on the ratio of slime to measured tailing. This follows for the reason that the slime has not been included in the material that has established the core-ratio. The core-ratios of each foot of drop of each hole also should be added; and if the determination of total volume is less than the amount of the measured tailing, the core-ratio may be increased in proportion to the deficiency, since the bulk measurement of the tailings clearly will be more reliable than the repeated gradual measurements of the core.

It may be of interest to present a specimen report of a drill-hole showing a correction of the estimates in the manner described. (See opposite page.)

Method of Correcting Determinations	
Tailing, cu. ft.....	4.06
Slime, cu. ft.....	1.125
Total, cu. ft.....	5.185
Slime = 28% of tailing	
Add core-ratios, 12.08	
They should be 23.50 which is 51%	
Theoretical volume of sample = $\frac{23.50}{100} \times \frac{27}{1} = 6.345$	
51% of 6.345 = 3.235	

This indicates that the tailing measured in the boxes (4.06) is 0.825 cu. ft. in excess of the measurement by each foot of drive. It is impossible to account for this discrepancy except by inaccurate measurements: both measurements are of

the same material, and there is no reason why the material should be greater in volume after it leaves the rocker than before. It should be reasonable therefore to add the amount of this discrepancy to each core-ratio.

Volume by tailing = 4.06	
Volume by core ratios = 3.235	
Difference = 0.825 = 25%	
Add for inaccuracy

13.474	4.01
Value of sample = 482 mg @ \$0.06 = \$28.92	
Corrected value = $\$28.92 \times \frac{37.2}{401} = \26.80	
Corrected value per cubic yard $\frac{\$26.80}{23.50} = \1.14	

By using this system of measurement, such conditions as compression or displacement of cores and the liability of automatic 'salting' by the intrusion of precious metals may be generally detected; but it is recommended that the engineer be conservative in increasing his stratum-recovery for low core-ratios, because: (a) The recovery may be obtained from only a portion of the amount of drop, which portion may have a standard core-ratio. Theoretically, then, it would be more reliable if core-ratios were established at every inch of drop. (b) The general tendency in drilling would seem to be for the gold to intrude into the pipe rather than to be excluded, on account of such factors as the pressure of the ground on the pipe, the inflow of seepage water, or the pumping action of the bit in churning.

In general, the engineer should endeavor to remove as many variables as possible: he should familiarize himself with such influences as the swell of the ground, the presence of clay, the effect of tight or loose strata, the distortion of the drill-shoe by driving, and natural irregularities such as boulders and excessive amounts of sand.

VARIATION IN GOLD. Variation in the size of the particles and the character of the gold or platinum should be carefully noted in the logs. Distinctive, coated, float, and flour gold, which are difficult to save in actual operation, should be weighed separately and so recorded, in order to guide the engineer in his final recovery-factor. Fineness of the gold should be carefully checked. It will be of advantage to weigh samples at every 5 ft. of depth below an established depth, to guide the operator as to his most profitable digging-depth. At the same time, the estimates per cubic yard should be discounted because of the necessity in operation of cleaning bed-

rock; ample provision for this increased depth should be made in the calculations. The physical condition of the deposit should be given careful consideration, and expected recoveries should be reduced to provide for any impoverishment of the bank by reason of tailings, voids, unprofitable blocks, or other exigencies. In shallow deposits, allowance for digging into bedrock to obtain the necessary depth for safely floating the dredge reacts to cause a serious reduction in the estimates per cubic yard. Furthermore, there is the personal element of the operating crew to be taken into consideration; and allowance should be made for the efficiency of their work.

DRILL-HOLES OF EXTREMELY HIGH OR LOW GRADE. It is generally expected in dredging that the grade in the immediate scope or range of drill-tests that are extremely high in value will give lower recovery; and inversely that the scope of drill-tests that are extremely low will give higher recovery than that indicated by sampling. The rule of averages, however, does not attach major importance to the localization of the precious metals, because each accepted drill-determination is utilized as a unit in the group from which is derived the average. From this reasoning, it would appear that holes of extremely high grade have relatively small scope. Some interesting calculations may be made from the figures of old records, if the drilling has been accurately done, to prove the number of cubic yards affected by any drill-hole of extremely high or low value. Two rules of finding averages are commonly utilized in drilling calculations: one is to divide the sum of all the particular quantities of the same sort by the number of them; or, in this case, to divide the sum of the products of the depths multiplied by the corresponding value per cubic yard, by the sum of the depths of all the holes. The alternative is to accept the mean between extremes by the process known as cancellation. No practical advantage has yet been discovered for calculating the number of cubic yards affected by holes of extremely high or low value, although there are possibilities in this direction. A combination of the two rules of average as described appears to be logical, inasmuch as the extreme values are assumed to have been actually found and therefore should have an influence on the general result, although their scope may be relatively small. Therefore it is suggested that, in any future comparisons of predictions and results, extremely high drill-holes be cancelled with the same number that are extremely low and the content of the ground be derived from the number of tests of average or mean value remaining. The extremes may be tentatively determined by means of a curve plotted in graphic form in order of value of the various holes.

To illustrate the method of computing the unit value by graphic formula, it is assumed that 23 holes spaced at regular intervals have been drilled to give accurate representative samples of a given piece of ground. The chart of these holes, shown herewith, warrants the cancellation of the \$1.14 with the 2c. hole, and the 45c. with the 2.3c. hole, leaving the value per cubic yard to be determined from the average of the 19 remaining holes, by

simply multiplying the depth by the value. Assuming the depths of all the holes to be equal, the value per cubic yard is 8.46c. If the average scope of each hole is 20,000 cu. yd., then, to be consistent with the average determination of 8.46c. per cubic yard, there would be theoretically 18,846 cu. yd. @ 2c. per cubic yard and 1154 cu. yd. @ \$1.14 per cubic yard within the scope of the \$1.14 hole. It is apparent, therefore, that if the gold sustaining the estimate of \$1.14 per cubic yard has actually been found, it represents only a small quantity of ground; the grade being extremely high, the volume of ground affected is extremely small. The calculation to determine the influence of extremes in value in a given area is as follows:

Effect of Cancelling Hole of Extremely High Value with Hole of Extremely Low Value

Let a = number of cubic yards affected by hole of extremely high value,
\$1.14 per cubic yard.

b = number of cubic yards affected by hole of extremely low value,
2c. per cubic yard.

20,000 = number of cubic yards affected by each of the 23 holes as shown
on the diagram.

8.46c. = value per cubic yard as determined by the diagram.

Then each hole will theoretically represent 20,000 cu. yd. with a precious-metal content of \$1692.

$$\begin{aligned} a + b &= 20,000 \text{ cu. yd.} \\ (a \times 114) + (b \times 2) &= 169,200 \\ a &= 20,000 - b \\ b &= 20,000 - a \\ (20,000 - b) \times 114 + 2b &= 169,200 \\ 2,280,000 - 114b + 2b &= 169,200 \\ 112b &= 2,110,800 \\ b &= 18,846.4 \text{ yd.} \\ a &= 1,153.6 \text{ yd.} \end{aligned}$$

Therefore, theoretically, in the scope of the \$1.14 drill-hole, 20,000 cu. yd., there are 18,846 cu. yd. of 2c. per cubic yard material and only 1154 cu. yd. of \$1.14 material.

This article aims, in a general way, to form a basis for systematic investigation and technical discussion of a problem of vital importance to the mining industry. Objections may be raised that the ground is too greatly disturbed by pipe-driving and drill-churning; that the distribution of the precious metal prevents representative sampling; that tight ground drills differently from loose; that natural conditions are against scientific or technical methods, and so forth. Perhaps investigation will demonstrate the advantage of an 8-in. or 10-in. drive-pipe instead of 6-in.; it may prove that drilling is not the correct method of sampling and valuing placer ground, or that it is economically impossible to evaluate accurately. On the other hand, intelligent working principles of general application may be evolved that will be of lasting value to the mining industry.

The amount of manganese ore containing 35% or more of manganese in sight in the deposits of the United States has been estimated by the U. S. Geological Survey at about 700,000, with 1,130,000 tons more in prospect. In addition, more than 17,000,000 tons of low-grade ore, containing from 5 to 35% of manganese, is estimated to be in sight in the known deposits.

Book Reviews

The People of Mexico. By Wallace Thompson, 427 pp. Published by Harper & Brothers, New York. For sale by the 'Mining and Scientific Press'. Price, \$2.50 net.

The sub-title says, 'Who They Are and How They Live', and that is what the author tells his readers. It is information that will be welcomed by many, including those who have been to Mexico; for a single journey to a country so diversified as Mexico will not suffice to give the traveler an intimate knowledge of the ways of its people; and even those who have resided there for a few years, at the mines, for example, may have found neither the time nor the opportunity to learn much about other parts of a country so large as Mexico. In his preface Mr. Thompson says that his book "offers itself as an anatomy of Mexico". It deals with a sick nation and it undertakes to diagnose her disease. The cause, he says, is racial; and this is the conclusion that he elaborates on the basis of the statistical, ethnological, and political data with which the book is enriched. Much of the information comes from the files of the Doheny Research Foundation, to which other recent writings on Mexico are traceable.

The first question he asks is, "What is a Mexican?" The answer is told statistically thus: "The 15,000,000 Mexicans include 6,000,000 pure-blooded Indians of fifty tribal strains, and until the exile of the upper classes under Carranza approximately 1,000,000 pure whites of Spanish lineage also called themselves Mexicans; between the two extremes are 8,000,000 mestizos (literally 'mixed bloods') to whose creation the two primary races have for four centuries contributed contrasting elements. It is the resultant hybrid whose numbers make him the typical Mexican of today." The author describes the physical qualities of these constituent races and asserts that "intellectually and psychologically the Mexican mestizo is more of a hybrid than he is physically. His body type has varied characteristics, although perhaps tending disproportionately to the Indian, but in his brain there seethes the continual conflict of intellectual and psychological predispositions which go back to cultures which in the history of humanity are thousands of years apart". Later he adds: "The Mexican is the victim of his mixed racial and cultural heritage, the plaything of primal forces which tend ever to neutralize one another in a personality often unworthy alike of his rich Spanish intensity and of his Indian simplicity". Under Spanish rule Mexico flourished, says the author, as it did under Diaz, who recalled the white aristocrats from exile and used them in the national service. With Diaz went the Spanish tradition. "What we have seen for the past ten years may be called the disintegration of the mestizo idea of nationalism into its component parts. What the Mexican calls 'personalism' in politics is but the remnant in the mixed stock of the self-assured superiority of the whites, and the anti-foreign laws and the bloody outrages upon the whites are but the Indian fear and hatred of white domination." That is the text of the book; this is the interpretation of Mexico that Mr. Thompson offers. The events that have brought Mexico into unpleasant prominence during recent years are attributable, he says, to "the uprising of the dark races against the white, a movement too mighty in its scope and too patent a peril to be glossed over by anyone who would speak truthfully of conditions in Mexico today". He quotes Esquivel Obregon, a publicist who ought to understand his own people, to the same effect: "At the bottom of all the troubles of Mexico is the prehistoric Indian civilization trying to destroy the European civilization".

The early Spaniards (1520) aimed at racial amalgamation, at inter-breeding, the result being a mixed race that in the end (1810) threw off the Spanish yoke. After 1823

the new race of mestizos set itself up as the inheritor of Spanish superiority. But the Indian blood asserted itself above the white, so that today the predominating factor is Indian. "A hundred years ago his [the Mexican's] Indian blood raised him against white rule; and today his Indian blood has almost conquered his white virtues." In short, "unless the white world again take up the burden, Mexico must inevitably slip back to the plane of pre-Spanish barbarism". Mr. Thompson has in mind something like Santo Domingo, it may be presumed, and he seems to suggest that the United States should interfere in Mexico as in Santo Domingo. If he does, he preaches a crusade for which I have no liking or sympathy, because I believe it would be a colossal blunder and deeply injurious to the welfare of the American people, whatever its consequences to Mexico. This is a feature of the book that I find repugnant, for the reason that it suggests the sinister propaganda of the oil-operators. On the other hand, Mr. Thompson gives much interesting and generally reliable information, for which alone the book is valuable, especially to the mining profession.

The vicissitudes of the white population are told by statistics. In 1810, at the time of the first revolution, there were 60,000 foreign-born in Mexico; in 1825, after the expulsion of the Spaniards, the number was not over 1000; in 1895 there were 3713; in 1900, 57,508; in 1910, 115,869. This growth coincided with the regime of Diaz, who welcomed foreign participation in exploiting the natural resources of the country. In 1920, after successive revolutions, only 5000 foreigners were residing in Mexico. Fully 87% of the population claim Spanish as their native tongue, but, as Madison Grant has said, "the language that a man speaks may be nothing more than evidence that at some time in the past his race has been in contact, whether as conqueror or as conquered, with the original possessors of such language".

"The white race", says the author, "has given to Mexico its language and its predominant culture. Racially, its chief contribution has been its part in the formation of the half-caste mestizo, and in the maintenance of that remnant of white aristocracy which, from time to time, has saved Mexico from utter self-destruction." According to this interpretation, the Indian blood of Diaz and of Huerta, for example, was in conflict with their white strain, and such cruelties as they perpetrated would be imputed, by Mr. Thompson, to the indigenous taint. One would presume from this that the Indian is incapable of being civilized or of assimilating the culture of the white people, including their humane qualities, as if the whites had never produced pirates and had never indulged in blood-thirsty atrocities. The memories of the Great War are too recent to permit any such self-complacent generalization. Mr. Thompson hammers his thesis again: "At times throughout Mexican history, hatred of the white man for his self-assumed superiority as much as for his oppression, has sprung into flame. Such a period is that in which Mexico is living today. The anti-foreignism expressed in the harangues of the leaders and in the Constitution of 1917 is basically Indian and basically anti-white. The Zapata phase of the revolutions of the last ten years was frankly and completely Indian, Zapata's object being, as he stated, to drive out the whites and mestizos and possess the rich state of Morelos for the Indians who were its indigenous inhabitants". Mr. Thompson uses the simile of the melting-pot, and insists that the fusion of races is incomplete, "each element tending rather to agglomerate with its own kind than to the creation of a fused alloy". Well, we are hardly in a position to brag concerning our own melting-pot, in which unfused lumps are only too discernible. We would like to see one of our learned Mexican friends reply to Mr. Thompson, for example, Señor Ezekiel Ordoñez. We can imagine the task would be easy and agreeable.

Reverting to the statistics. Here are more:

Year	Percentages			Approximate numbers		
	White	Mestizo	Indian	White	Mestizo	Indian
1519			100			6,000,000
1810	18	22	60	1,080,000	1,320,000	3,600,000
1905	15	50	35	2,100,000	7,000,000	4,900,000
1910	8	52	40	1,150,000	8,000,000	6,000,000

The climate is a decisive factor in racial development. "Not only is the pure white unfit for manual labor, but the mixed blood, almost in direct ratio to the predominance of the white strain, is physically weaker and physically less resistant to climatic conditions than his more Indian brother." That is why the Indian is first in "selective animal force". As the author says, "With his short generations and his adaptability to the Mexican climate, the Indian contribution to the mestizo is overwhelmingly one of vital force". He demurs to putting the mestizo first in "sociological importance", as is done in an official paper. "The culture and institutions of Mexico", he says, "are white—or they are Indian; the mestizo has nothing of his own to contribute, and either emphasizes the white as he did under Porfirio Diaz or rides in a wild orgy of Indianism as he is doing today." The preface is dated November 1, 1920. For the mestizo the author has contempt only; for the Indian he has a bitter dislike. This will not be shared by most mining engineers familiar with Mexico; they have found the Indian more trustworthy than the mestizo, although less smart. However, he recognizes that the breaking down of the color line is complete in Mexico and it has given the Mexicans a homogeneity unlike those of the peoples south of them, or, he might have added, north of them. What Mexico needs at this juncture is a leader and a master, we are told: "An aristocracy of those who understand and live and serve as well; an aristocracy fed deep with ideas, giving them out, growing with them and with its people; an aristocracy with institutions, a great, free institution of honest, devoted government, institutions of learning where true leaders, ever renewing themselves, may be brought up, schools where hand and heart shall be trained together, where peon and aristocrat may meet, and understand each other, always". That is excellent, but Mexico is not the only country that needs such an aristocracy; the Rio Grande does not separate us from a similar ideal. Mr. Thompson finds such an aristocracy in "the Great Mexicans who alone must take up their country's regeneration" and are waiting "silent and uncomplaining . . . for the support which can come only from those in whose hands rests the scepter of the white man's world". In short, the exiled Spaniards and mestizos await American support for re-establishing their domination in Mexico. That is the message of this book. For those who advocate intervention, it will provide arguments; to all interested in Mexico it will give timely information, and warning.—T. A. R.

Elements of Fuel Oil and Steam Engineering. By Robert Sibley and C. H. Delaney. Second edition, revised, enlarged, and re-set. 466 pp., 6 by 9, ill. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

This is the second edition of the well-known treatise that met with such a favorable reception when published first in 1918. The leading author is the talented editor of the 'Journal of Electricity and Western Industry' and was formerly professor of mechanical engineering at the University of California. The book has as its underlying theme a study of fuel-oil power-plant operation, and the efficiency of oil-fired plants. The subject matter has been treated in three main subdivisions: on exposition of the elementary laws of steam engineering; the process involved in the utilization of fuel-oil in the modern power-plant; and the testing of oil-fired boilers. The elementary laws of steam engineering are set forth in a new manner, in that the viewpoint is taken of the oil- and not the coal-fired plant. The results

are given of a considerable amount of labor and analysis in connection with burner, furnace, and fuel-oil tests. Definite suggestions are made for carrying out fuel-oil tests. Many illustrative problems on steam-engine and boiler economy are given. The new edition is entirely re-written, and much new material has been added; many of the newer portions of the work have appeared in either the columns of the 'Electrical World' or in the 'Journal of Electricity'. The treatise has taken its place as a standard text-book on the subject.

Highway Engineering. By George R. Chatburn. John Wiley & Sons, Inc., New York. 379 pp., illus. For sale by 'Mining and Scientific Press'. Price, \$3.

In this treatise the author, who is a lecturer on highway engineering at the University of Nebraska, has endeavored to bring into a brief space the most recent and best practice as determined by experience and research. The text is more commonly concerned with rural roads; these have been covered in greatest detail. Pavements have been considered with a view to their use for country roads, although the treatment may be regarded as sufficiently comprehensive to form a beginning or short course for those who are desirous of taking up city paving work. The book is intended primarily to form one of a series in agricultural education; it should, therefore, be read with interest by the layman, and will serve as a useful reference book for professional engineers, road builders, and road officers. The principal subjects dealt with include: I. The Economics of Road Building. II. Road Location. III. Types and Adaptations of Roads. IV. Drainage. V. Culverts and Bridges. VI. Earth Roads. VII. Sand-Clay Roads. VIII. Gravel Roads. IX. Broken-Stone Roads. X. Pavement Foundations. XI. Brick, Stone, Wood, and other Block Roads. XII. Concrete Roads. XIII. Bituminous Roads. XIV. Surface Treatment to Mitigate and Prevent Dust. XV. Revenue Administration and Organization. XVI. Miscellaneous.

Oil Land Development and Valuation. By R. P. McLaughlin. McGraw-Hill Book Co., Inc., New York. 200 pp., illus. For sale by 'Mining and Scientific Press'. Price, \$3.

The author of this treatise, who was formerly the State Oil and Gas Supervisor of California, has produced an excellent volume in which an outline is given of the steps that are necessary for the full and proper development of lands that have been shown to be oil-bearing. A detailed study is made of the precautions that must be observed with regard to construction and maintenance of wells that tap the original source of supply, the information having been based on the author's long experience in making engineering and geological investigations of oilfields. The contents of the book are as follows: I. Development Program. II. Drilling of Wells. III. Assembling Information Relative to Underground Conditions. IV. Production of Oil. V. Repairing, Deepening, and Abandoning Wells. VI. The Value of Oil Land.

Dictionary of Chemical Terms. By James F. Couch. 204 pp. D. Van Nostrand Co., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

This is an excellent little book that has been compiled to cover a new field, and will be found to be of value and convenience to the chemical specialist as well as to the engineer or layman. It bears the impress of careful preparation and editing. The author, showing commendable breadth of view, invites the fullest constructive criticism from readers with reference to any errors that may be noticed. Such an attitude should ensure accuracy in subsequent editions, if a critical examination by specialists discloses any fault in the present one.

REVIEW OF MINING

MINERALS SEPARATION V. BUTTE & SUPERIOR; HEARINGS ON ACCOUNTING

The instructions of Judge Bourquin to the master before whom the account for damage due Minerals Separation from the Butte & Superior Mining Co. for infringement of froth-floatation patents is peculiar in its wording, and, in the opinion of attorneys, is slightly doubtful in its interpretation. In his instructions Judge Bourquin says that the master, keeping in mind the distinction between processes and standards, shall be governed by the rule that the standard in this accounting shall be "any standard that may be duly made to appear in respect to subsequent infringement".

Earlier in his decision the Judge said that, while the points involved are rather new, the principle to be followed was the decision of the Supreme Court in several somewhat similar cases that "the fruits of the advantage which he (the infringer) derived from the use of the invention were those over what he would have had in using other means then open to the public and adequate to enable him to obtain an equally beneficial result". This Judge Bourquin said clearly meant that "what the infringer thus gains is also what the patentee is presumed to lose, so far as accounting for profits is concerned and equity is done when all such gains are taken from the infringer and given to the patentee", adding, "it seems fairly clear that this is the import of the quoted language of the Supreme Court". Already the recorded testimony, briefs, arguments, and decisions in the several froth-floatation patent suits in the various courts of the United States exceed 15,000,000 words, and as yet no clear definition of the scope of these patents has been arrived at.

ANACONDA COPPER SPENDS \$500,000 MONTHLY TO PRESERVE ITS MINES

It is costing the Anaconda Copper Mining Co. \$500,000 per month to stay closed down. Production of ore was stopped in April, but it was not until toward the latter part of that month that all departments ceased functioning. Ore and concentrate on hand were cleaned up and it is probable the actual expenses of Anaconda in the first months of its shut-down were considerably in excess of this sum. This is an example of why mining men preferred to keep their properties open until the absolute stagnation in the industry demanded that production of copper cease. Anaconda today is employing approximately 2600 men. These are mostly care-takers, watchmen, and mechanics to supervise the machinery and keep it from deteriorating through idleness. While wages have been cut, they are still higher than prior to the war.

In addition to its shut-down expenses, Anaconda's bond interest is, of course, continuing. The company has outstanding \$25,000,000 in 6% bonds and \$25,000,000 in 7% bonds, both issues maturing in 1929. Here is an interest charge of \$3,250,000 per year, which, with current expenses of \$500,000 per month, means that it is costing the world's largest copper producer \$10,000,000 per year to 'stay on earth'. Anaconda, however, has a wealth of fixed and liquid assets and can stand the strain. At the close of last year net current assets exceeded \$67,860,000, of which cash and accounts receivable amounted to nearly \$25,000,000 and metals amounted to \$32,500,000. This latter account has

undoubtedly been very much reduced by now. After providing for the bonds at par, Anaconda still has over \$7 per share in 'net quick' for its 2,331,000 shares of stock.

PHELPS DODGE-ARIZONA COPPER DEAL LIKELY TO BE CONSUMMATED

It is believed certain that the Phelps Dodge Corporation will take over the property of the Arizona Copper Co., a British corporation. The deal is considered closed except for the compilation of the final audit and minor details of supplies on hand. Auditors from the New York office of Phelps Dodge are busy with the auditing of accounts. Current negotiations are on a basis of exchanging about \$5,000,000 par of Phelps Dodge stock for Arizona Copper common stock. Although it has \$50,000,000 authorized capital the Phelps Dodge Corporation never issued more than \$45,000,000. Arizona Copper also has a preferred issue, to acquire which Phelps Dodge will make additional payments possibly in cash. In the event of the transfer, the Arizona & New Mexico railroad, which is over 100 miles long, from Clifton to Hachita, by way of Lordsburg, would become part of the El Paso & Southwestern system. The lighting and power service of the entire district has been transferred from the Arizona power-house, at the smelter below Clifton, to the Phelps Dodge power-house at Morenci, where the Diesel engines are more economical. It is reported that J. P. Hodgson, formerly manager for the Detroit Copper Co., at Morenci, is to take Norman Carmichael's place as general manager of the Arizona Copper plant.

PRESENT OPERATIONS OF GARFIELD SMELTER

A. H. Richards, general superintendent of the Garfield smelter, recently discussed the operations at that plant. He predicted that Utah will lead all other States in the output of silver this year. The Garfield smelter, by slight changes in its smelting processes, is now treating a large tonnage of silver silicious ores from the Park City and Tintic districts. As a result of improvements at the Garfield smelter, Mr. Richards stated that the plant is now the largest of its kind in the world. In 1918, the smelter produced an average of 643,643 lb. of copper per day, with a payroll of \$209,890 per month; in 1920, it produced 340,422 lb. of copper per day, with a payroll of \$99,152 per month, whereas during the first six months of 1921 it produced 221,212 lb. of copper per day, and the payroll was about \$60,000 per month. At present, about 500 men are employed. Mr. Richards stated that the maximum capacity of the plant is 5000 tons per day, whereas at present an average of 1200 tons of ore is being treated per day. The present output of gold is 100 oz. daily and of silver about 10,000 oz. daily. The plant consumes 117 bbl. of fuel-oil and 223 tons of coal per day. Mr. Richards expressed the opinion that the Utah Copper Co., the largest shipper on the smelting company's list, would resume operations early in 1922. The smelting company recently shipped the last of the 17,000 tons of Utah Copper blister that has been stored in the smelter yards. This bullion was shipped by way of San Francisco and the Panama Canal to the Atlantic seaboard, which resulted in a saving of about \$4.50 per ton, as compared with the all-rail route.

PURCHASING POWER OF GOLD

Recently Mr. Samuel Evans, the chairman of the Crown Mines, Ltd., referred, at the annual meeting of shareholders, to the variations that have taken place in the wholesale prices of commodities in England since 1782, as reproduced in the chart on the opposite page. The data were obtained from the index figures prepared by Jevons for the years 1782 to 1860, and by Sauerbeck and 'The Statist' for the years 1860 to date. From this it will be seen that the purchasing power of gold fell between 1786 and 1809, it rose between 1809 and 1849, it fell between 1849 and 1873, it rose between 1873 and 1896, and it fell between 1896 and 1920. During the 139 years the value of gold was seriously depreciated on two occasions; and this was due, in both instances, to the excessive use of inconvertible paper money. The first period, during the operation of the Bank Restriction Act, which provided for the suspension of specie payments by the Bank of England, lasted from 1797 to 1821; it has been described as the dark age of currency in England. The second period commenced with the issue, under the Currency and Banking Notes Act of 1914, of £1 and 10-shilling legal-tender notes, commonly known as Bradburys; it will last, in the opinion of Mr. Evans, until Great Britain reverts to sound money, with a free market for gold. The free market exists nowhere today except in the United States.

ARIZONA

Kingman.—Plans are being made to develop at a depth of 700 ft. the orebody already opened to a depth of 400 ft. in the Katherine mine. The ore blocked on the first three levels totals 120,000 tons of an aggregate value of \$1,563,472, according to one report. This ore is sufficient to warrant the erection of a 300-ton mill.

An east-west vein 26 ft. wide was recently opened in the Gold Chain mine. A drift is now being extended to the east in the original foot-wall vein at a depth of 100 ft. in the direction of the Comstock Consolidated, or Curtin-Mahoney property. Cross-cuts are to be driven through the vein at 100-ft. intervals. This work is to be followed by the sinking of the shaft to a depth of 200 ft., where a level will be established and cross-cutting done.

Tombstone.—The Old Guard mill is running regularly and is reported to be getting good extractions. The Mellgren mill is at present running the tailing dump at the old Fisher mill. The Bert Holland mill is temporarily closed but will be going shortly. Another tank and vacuum-pump will be installed to increase the water flow, and when the mill starts it is planned to maintain regular operations, as no doubt the water flow will be made satisfactory by the installation of the pump.

ARKANSAS

Zinc.—The Odum zinc mine, the last to cease operations in the north Arkansas field, has just closed down. There is not a mine in operation in the field; this is the first time that such a condition has existed in 20 years. The last concentrate sold by the Odum company brought \$14 per ton, which was below the cost of production.

CALIFORNIA

Amador City.—The following gentlemen attended the monthly meeting of the Mother Lode mine superintendents, held at the Fremont mine on August 27: W. J. Loring, of San Francisco; G. A. Rose, of San Francisco; George Vrang, of San Francisco; S. E. Robbins, engineer at the Fremont mine; E. Higgins, consulting engineer; C. F. Burt, mining engineer at the Bunker Hill mine; A. D. Stevenot, superintendent of the Carson Hill mine at Melones; Stanley Arnot, superintendent of the Plymouth Consolidated mine at Plymouth; I. B. Hoxsie, superintendent of the Fremont mine; O. D. Rohlf, superintendent for the Amador Gold

Mining Co.; R. E. Christensen, superintendent of the Bunker Hill mine, and N. W. Hyler, president of the Bunker Hill mine.

Bishop.—The 75-ton mill of the Wilshire gold mine has been in operation since July 27. A concentrate averaging \$200 per ton is made from ore averaging \$7.50 per ton. It is expected to increase the grade of the mill-heads to \$11 per ton and to increase the capacity of the plant to 90 tons per day. Mining is done by the shrinkage-stope system. The concentrate is shipped to the plant of the U. S. Mining & Smelting Co., at Midvale Utah.

Grass Valley.—The 80-stamp mill of the Empire company is again operating at full capacity, the output approximating \$90,000 per month. Work in the Pennsylvania mine, which is operated in connection with the Empire mine, is to be resumed. The mules and sundry mine equipment have been replaced in the workings and the stopes and shafts are being repaired. The milling will all be at the Empire plant, an electric railway having been built to transport the ore.

Marysville.—Preparations are under way at the local plant of the Yuba Manufacturing Co. for the building of three large gold-dredges for the construction of which the company has contracts. These dredges will be built at a cost of \$3,000,000. Material has already commenced to arrive, and actual building operations will be in progress here by October 1. Several hundred men will be employed in the shops.

Placerville.—Work has started at the Grover mine on Slate mountain near Georgetown. Trucks are being used to haul machinery and supplies to the mine. The Grover has produced some rich ore, but has never been worked to depth. —Discovery of a deposit of rich gold ore near Kelsey is reported; several nuggets have been found, including two weighing 7 and 5 oz., respectively. The discoverers state that an important deposit has apparently been found.

Randsburg.—The California Rand Silver, Inc., has declared regular dividend No. 20, calling for a distribution of \$25,600. This makes a grand total to date of \$992,000. The recent monthly report states that the drift on the ninth level has been "in shipping ore for almost the entire distance of 342 ft. with good ore still showing in the face, thus opening the largest body of ore in the history of the mine". During August, 3648 tons of milling and shipping ore was mined, 1465 tons of which went to the smelter. The surplus on September 1 was \$314,000. The annual meeting will be held at Bakersfield on September 10.

Redding.—The Valdor Dredging Co. has completed a thorough prospecting of placers along the Trinity river at Poker Bar, below Lewiston, and the officials are considering the advisability of dredging the deposit. The ground is reported to carry a fair quantity of gold. The company is working a dredge near Junction City. A small dredge was operated several years ago at Poker Bar, but was not sufficiently powerful to work the placers to advantage. —Mining of gravels carrying gold and platinum is proceeding along Beegum creek, with many operators said to be realizing profits. High water has hampered activities all summer, but the miners expect to work the lower deposits during the fall months unless early rains set in. The placers have been located for miles along the creek and for a considerable distance on each side.

COLORADO

Alma.—Local operators have secured a lease and bond on the old Russian mine and active operations are planned. —Supplies have been delivered at the lower adit of the London mine, and the adit, 2200 ft. long, will be extended to the London vein, 2000 ft. distant. The property closed during the war period because of shortage of labor and high cost of mining supplies.

Breckenridge.—The Pennsylvania mine and mill are again operating and silver-lead concentrates are being saved for shipment to the A. V. smelter at Leadville.—The King Solomon Syndicate has uncovered a 4-ft. vein of silver-lead ore on the Wheel of Fortune, and a body of manganese ore, 18 ft. wide, has been exposed on another of the King Solomon group at Frisco. The silver-lead ore assays 300 oz. in silver for closely sorted material.

Cripple Creek.—Three properties on Ironclad hill, the Jerry Johnson, Forest Queen, and Hardwood, the last named owned and operated by the United Gold Mines Co., are producing and shipping.

Idaho Springs.—Operations have been resumed by the Gem Mining Co. Contractors are starting on the connection with the old workings of the Gem and Franklin mine of the Silver Age group. A strong orebody has already been opened and ore-reserves are being increased. The Newton mill has been overhauled and is in shape to receive and treat ores.

Kokomo.—The Kokomo-Reeen company is mining ore from a 2-ft. vein recently opened. Assays show as high as 3 oz. gold, 6 oz. silver, and 12% lead. The property has been idle for some years.

IDAHO

Coeur d'Alene.—The Federal Mining & Smelting Co. has declared a dividend of 1% on its preferred stock. This is equivalent to approximately \$120,000. Payment will be made on September 15.—Preparations are being made to drive a new 3000-ft. tunnel on the Ajax Mining Co.'s property.—The Big Creek Mining Co. has added a 60-hp. electric motor and other equipment, and expects to increase the production that has been maintained continuously for several months. G. Scott Anderson is manager.—George MacDonald, contractor for the Caribou Mining Co., has finished his first contract on the tunnel at the mine, and has taken a second contract calling for an additional 100 ft. He is following a well defined vein that may enter the main orebody at any time.

Six feet of galena milling ore has been found on the Hilarity mine of the Pine Creek Mining Co. The body is in quartzite, which is unusual, as many orebodies of the Pine Creek district have been in slate. The strike was made at a depth of 200 ft. H. W. Ingalls is in charge.—The U. S. Silver-Lead Mines Co., operating in the Eagle district, has disclosed ore in both drifts from the lower tunnel level. This is at a depth of 350 ft. on the dip of the vein.—The Columbus Mining Co., operating a mine south of the U. S. Silver-Lead, is developing a body of lead ore 1½ ft. wide in a vein 4 ft. wide. The vein contains a little gold and silver. An engine, boiler, and compressor have been ordered and are expected to reach the property soon.

Talache.—The Armstead Mines Co. is now employing 60 men. The company has purchased machinery for a flotation plant, the construction of which will be hastened. Other new equipment includes an air-operated hoist and cage for the main raise, and electric signalling system, an underground electric-lighting system, a new air-compressor, six new stopping drills, and a storage-battery locomotive. According to H. H. Armstead, a hotel building containing 44 rooms, and a number of artistically designed bungalows, are being constructed. Ore from the Little Joe mine averages 20 oz. silver, 0.1 oz. gold, 1% zinc, 1% lead, and 0.7% copper.

MICHIGAN

Houghton.—Commercial and other interests of the various copper districts are taking up the matter of stimulating the demand for copper-made articles, and the slogan, 'Buy something made of copper', is being extensively adopted. Numerous new uses for copper are being sug-

gested and it is likely that some of them will be found practicable. It is believed copper will again come into general use in the household in the form of utensils of various sorts, such as copper pans and kettles, and that more of it, too, will be used for roofing and gutter purposes, water and gas pipes, fencing and screens. Copper signs for highways and copper license plates for autos also have been suggested. Arizona, it is said, will seriously consider the adoption of the auto copper plate for its 1922 or 1923 licenses, and the plan also will be proposed to the officials of Michigan. Out of all the discussion centering about new uses for copper, it is believed much good will come and that new markets will be opened that will ultimately tax the production of the mines. In this campaign it is agreed that the newly organized Copper & Brass Research Association will be a potent factor.

Estimated production of the four companies in the Lake district in August was 4,750,000 lb., divided as follows: Copper Range, 2,300,000; Quincy, 1,000,000; Mohawk, 1,130,000; and Wolverine, 320,000. The output for the summer months has remained at about these figures and probably will continue at this rate until the metal market warrants a decided increase. Present production is less than a quarter of that of 'normal' years, the Lake district turning out better than 20,000,000 lb. per month under favorable metal-market conditions. The figures for the four producing companies are representative of the extent of actual mining operations only. In addition, Calumet & Hecla, which is not mining a pound of metal, continues to operate three furnaces in a cleaning-up process. When mining was suspended, C. & H. had a considerable accumulation of mineral and this, with cupola blocks, is being converted into anodes for treatment in the electrolytic plant, the cathodes being returned for re-smelting into special shapes as may be required in metal orders from abroad.

Copper Range is making no effort to increase its working forces. It is not going 'outside' for men, as has been reported, although it has taken on experienced workers who have come here from the iron districts looking for employment. Places are being found for underground men of experience, whether from this district or others, but no attempt is being made to build up the organization, which is only about half of normal. There has been a considerable labor turnover at all three mines of the company throughout the summer, a condition not unusual during this period of the year. The gain in the payroll at Champion, Baltic, and Trimountain in August was only 20.

MISSOURI

Joplin.—The American Zinc, Lead & Smelting Co. has purchased the High Five mining property near Waco from Temple Chapman and associates of Joplin. The consideration was about \$250,000, but under the terms of the contract-sale a long period of years is given for the payment. It is expected that the purchasing company will co-operate with the other producers of the Waco district to drain the ground to a 320-ft. level, 10 ft. deeper than operations have yet been carried on in that district.

MONTANA

Butte.—The Davis-Daly company reports for the quarter ended June 30, total receipts of \$257,199, and total disbursements of \$171,602, including Federal taxes, leaving a net profit of \$85,597. In the first three months Davis-Daly earned a net profit of \$39,206. The report says: Practically all work at the property not immediately essential has been discontinued and the organization reduced to what seems to be the minimum practicable for single-shift operation. Sunday operation has been discontinued and hoisting of ore is confined to six days per week. The number of tons hoisted per shift operated was probably the highest in the

history of the property, with operating costs low. The grade of ore was a little below the average.

Production at the Hibernia has been quite active and early in June the sinking of the shaft to the 750-ft. level was started, which will determine the grade of the ore. Total development for the quarter, including Hibernia, was 3055 ft., comprising 1122 ft. of cross-cuts, 1051 ft. of drifts, and 882 ft. of raises. The average assay of ore shipped from the Colorado mine was 5.44% copper and 5.31 oz. of silver per ton, and from the Hibernia 26.41 oz. of silver per ton.

The International Minerals & Metal Corporation, that was formerly known as Beer, Sondheimer & Co., has transferred to the Anselmo Mining Co. the following lode claims: Anselmo, Anselmo No. 2, Trifle, Gnat, Hope, and Marquis. The deeds carry revenue stamps, indicating that approximately \$900,000 is involved in the transaction. E. L. Ralston is manager of the Anselmo properties, and J. C. Pyle is consulting engineer.

NEVADA

Argentite.—The Natural Soda Products Co. of Inyo county, California, has let a contract for extending a tunnel 100 ft. and for 200 ft. of drifting from the 100-ft. shaft. This work will be done on the Sanger-Taylor, which the company holds under an option. There is a 350-ft. hill on the claims. The vein strikes north through this hill and outcrops on the flat at the northern side. A drift adit has been driven 70 ft. into the northern side of the hill. The shaft is sunk on the flat. A 12-in. width of 1500 to 2000-oz. silver ore has been found on the surface 200 ft. south of the shaft and in what is thought to be the extension of the vein in which the shaft is sunk. A six-mile road connecting Argentite with the main highway has been completed and a 6-hp. hoist, now at Goldfield, will be hauled to the Sanger-Taylor in a few days. E. J. Curless, of Goldfield, has the contract for the 300 ft. of work. W. W. Watterson, of Bishop, president of the Natural Soda Products Co., visited Argentite recently.

Cortez.—A raise is being driven at 60° from the lower or Arctic tunnel of the Consolidated Cortez Silver Mines Co. to connect for ventilation with the Garrison tunnel workings, 360 ft. above. This raise is in the rather soft porphyry composing the big dike that cuts nearly vertically through the mountain. The lower adit exposed high-grade ore in fissures in the limestone, near the main dike. Large blocks on the upper tunnel-level remain unexplored and applicants for leases have offered a 40% royalty to work this territory.

Divide.—The Belcher is to resume work on the 85-ft. level and later it is planned to resume on the 550, where ore has been found in small quantity.

Goldfield.—One hundred tons of \$60 ore was produced by the Silver Pick from the winze below the third level and stoping from the bottom has given a production of 150 tons of \$40 to \$50 ore. Face samples from the stope assay \$70 to \$80. The ore was 7 to 8 ft. wide in the winze. There is exposed in a 15-ft. raise from the drift in ore on the third level a 2½-ft. width of \$100 to \$650 ore. A sub-lessee has saved 10 tons of \$100 ore from a seam found on the surface and in the hanging wall of the vein.

Hamilton.—The Eureka-Hamilton property on Treasure hill has developed ore on its Pocatello and Argyll claims estimated at nearly \$300,000. W. H. Blackburn, engineer for the Tonopah Mining Co., spent a week in sampling the property and is negotiating for the purchase of control. The property is developed by a 550-ft. tunnel and several shafts. A raise and winze from the tunnel are both in good ore. The claims, 17 in number, adjoin the once famous Eberhardt-Aurora mine.

Jarbridge.—The Elkor Mines Co. is producing at the rate of 100 to 125 tons daily, this being the capacity of the com-

pany's cyanide plant.——At the property of the Legitimate Mining Co. gold ore of good grade is being blocked out. Experimental work is in hand, with a view to determining the best process for milling the ore.

Luning.—Prospecting work is being done at a number of points along the porphyry belt at Lucknow, nine miles north of here, and several claim-owners have found good ore. Watson and O'Hoye, discoverers of the ore on the Faith group, have sunk 30 ft., and are sacking \$45 ore. The district has a plentiful supply of water from springs, and ore can be delivered to the custom mills at Millers for about \$4 per ton.

Mina.—Work on the Mineral county electric-transmission line, extending from Hawthorne to the Simon and Candelaria districts, is making good progress. The hole-digging crew is

Western Part of South Dakota, Showing Hill City

nearing Simon and the poles and wire have been delivered. The poles were bought in Idaho and were treated with creosote en route in Utah. The county has bought the remainder of the line extending from Hawthorne to Lundy, California, where the power is generated. Branch lines will be required in the near future for operations at Marietta, Garfield, and other districts tributary to Mina.

Round Mountain.—Lightning destroyed the transformers at the Sunnyside mill of the Round Mountain Mining Co. Three new transformers were obtained within 48 hours at Tonopah and Goldfield and milling was resumed with only brief delay. The mill is operated by lessees on the quartz mine, the company confining its activities to the placer gold deposits. L. D. Gordon, president and manager, went to the property from San Francisco.

Tonopah.—The Tonopah Extension Mining Co. has unwatered the Victor shaft down to the 1880-ft. level and is now making preparations to resume exploration and development work to open up the orebodies that have been developed on every level above the 1760. Several days will be spent in cleaning up the floors of the cross-cuts and drifts and clearing the tracks. It should not take long to prove whether the Murray, the Merger, and the Victor veins extend at least to this depth in the Extension mine.

Peter Oslund, with more than \$25,000 to his credit in a Tonopah bank, left here a few days ago for a visit to his old home in Sweden. Oslund made the money leasing on the Halifax. With less than two months remaining before his lease would expire, Oslund's partner quit him. Oslund then decided to invest another and last \$50 in the lease and within ten days he opened ore. From then until the lease expired, six weeks later, he shipped ore of a net value to him of \$25,000. Oslund is traveling to New York in a Ford automobile which he will take with him to the old country.

—The tailing-treatment plant at Millers of the Belmont is to resume in a few days. The plant, which has a capacity of 150 tons daily, will be in charge of M. A. Tanner.

The Golden State Divide Mining Co. has purchased the surface equipment owned by the defunct Mutual Divide Co. This plant was one of the best erected during the big boom in the Divide district. The purchase includes one mile of power-line, which will be used for connecting the Klondyke shaft with the trunk-line of the power company. When the strike was called the Golden State was shipping 100 tons per week to the Desert mill at Millers. During the four months of the strike the management never lost a shift in the mine, and it is estimated now that the Golden State has 2000 tons of good milling ore a the surface and broken in the stopes.

Tuscarora.—The re-opening of the old mines of this district is again being discussed, Salt Lake men having become interested in the project. These men are considering a plan to develop electric power. The surrounding region has many good sites for hydro-electric plants, with an abundance of water. Rich gold ore has been found in the western part of the district, on claims adjoining the Rose property.

SOUTH DAKOTA

Lead.—The Free Gold Milling Co. has been organized by Denver and Eastern men, headed by D. L. Killen as president and trustee, to take over and operate a property consisting of 16 lode claims, four miles from Hill City, in the Black Hills district. Machinery and equipment is on the ground, together with a stamp-mill of 50 tons daily capacity.

UTAH

American Fork.—Shipments from this district have been delayed, owing to heavy rainstorms, which washed out the road. The American Leasing Co. has been making shipments which average 70 oz. in silver with some gold and lead.—The Mercer-Wild lease at the Dutchman mine has a shipment of 50 tons of ore ready for the market.—At the Pittsburg mine some high-grade ore is being mined and sacked.—At the Comstock property, adjoining the Pittsburg, a winze has been started on a small streak of unusually high-grade lead carbonate ore.—The Miller mine is being operated by New York people under a lease and bond, and a small force is engaged on development work.

Eureka.—Development work has been started at the Tintic-Silver Mining Co.'s property, which adjoins the Lehi-Tintic holdings in the northern part of the district. A fleet of trucks is being used to transport supplies up Broad canyon to the property. It is understood an adit will be driven into the mountain, preparatory to sinking on the vein.

A car of silver bullion recently was shipped by the Tintic Milling Co., which contained between 30,000 and 40,000 oz. The company is securing most of its ore from the old Swansea property. At the present time, the 500-ft. level of the Swansea mine is in good shape for production. Most of the ore so far sent to the mill is material which was caved down during the last 12 years while the property has remained idle. A car of copper bullion was also forwarded by the milling company recently to Eastern purchasers.

Ore shipments for the week ending August 27 totaled 161 cars, of which the Tintic Standard shipped 46; Chief Consolidated, 37; Victoria, 18; Eagle & Blue Bell, 14; Dragon,

12; Iron King, 9; Iron Blossom, 7; Bullion Beck, 5; Swansea, 3; Mammoth, 3; Bowers, 1; Eureka Mines, 1; Gemini, 1; Centennial-Eureka, 1; Uncle Sam, 1; Sunbeam, 1.

At the Victoria property, the orebody previously developed on the 1350-ft., 1450-ft., and 1550-ft. levels, has been entered on the 1700-ft. level, according to William Owens, superintendent. This is by far the largest ore deposit in the mine. A new heading is now being driven on the 1875-ft. level.—About ten lessees are now working the old Grand Central property and shipping 10 carloads per month, according to W. D. Loose, manager.

Frisco.—During the past month four cars of medium-grade ore have been shipped from the Quad Metals mine, according to Grant Snyder, manager. Fifteen men are now employed at the property, and the main development work consists of sinking a winze from the 700-ft. level. Ore running as high as 100 oz. in silver and 50% lead has been shipped. From two of the orebodies—the Carbonate and the Rattler—about \$900,000 of metal has been extracted.

Park City.—Concrete foundations for the new concentrating plant at the Silver King Coalition property are in place, and steel construction has been started. Recent developments in the mine, particularly in the O'Brien fissure zone, have been encouraging. In the Silver Hill claim an orebody was recently opened that contains gray copper ore assaying \$20 in gold, 150 oz. in silver, and 34% copper.—Ore shipments for the week ending August 27 totaled 1378 tons, as compared with 1212 tons for the preceding week. The Silver King Coalition shipped 593 tons; the Judge companies, 316; and the Ontario, 469.

Sunnyside.—Announcement is made by the Utah Fuel Co. that the fire which has been burning in Sunnyside mine No. 2 since August 17, 1920, has finally been extinguished. The fire was one of the most disastrous, as well as stubborn, in the history of coal-mining in the United States. Fire-fighters worked more than 10,000 shifts before the fire was subdued. The mine had a capacity of 1500 tons of coal per day, and is one of the largest owned by the company.

WASHINGTON

Republic.—The Knob Hill mine is working 10 men and making regular shipments to the Trail smelter, stoping from its new 600-ft. level. The ore on this level is the best ever found in the main vein. Samples taken from the faces of the stopes run high in gold and carload lots average from \$25 to \$35 per ton at foreign prices for silver.

Colville.—Lessees of the Old Dominion mine in the course of development have shipped to the Trail smelter 133 tons of ore of good grade.

BRITISH COLUMBIA

Alice Arm.—J. and G. Strombeck and A. Miner have found some exceedingly rich ore on the Toric group, on the Kitsault river. The lode, known as No. 2, averages 4 ft. wide and has been traced for 300 ft., but the high-grade ore is 22 in. wide, on the foot-wall side. This ore contains native silver and samples have run up as high as 9600 oz. per ton. An average of three samples from which all visible native silver was removed gave 107 oz. per ton. The No. 1 lode, which runs parallel to the No. 2, is 5 ft. wide and assays 24 oz. in silver per ton. The owners have started a tunnel to cut the new discovery at a depth of 40 feet.

Greenwood.—A local syndicate has been formed for the purpose of building a 100-ton custom concentrator, provided the neighboring mines will guarantee to supply 100 tons of ore daily. Another local syndicate has commenced to develop the Riverside mine, at Rock Creek.

Stewart.—J. J. Coughlan and associates, of Vancouver, have bonded the Silverado group from John Haake, of Stewart, and Stewart Brothers, of Victoria. A substantial

payment has been made. The bond calls for certain improvements in the way of equipment and development. The vein is from 4 to 14 in. wide and contains freibergite. A sample taken by the resident engineer of the Provincial Department of Mines last year gave \$10 in gold and 360 oz. in silver per ton and 5% of copper. There are 12 tons of this class of ore sacked ready for shipping. The new owners will establish a permanent camp at the mine and build a light tramway to tide-water, a distance of only 8000 ft. R. L. Clothier has been placed in charge of the development of the property, which is to be commenced at once and continued through the winter.

George Mehfeld has run into a rich ore-shoot in the tunnel at the Idaho group, on the Marmot river. The tunnel was started on a stringer that has opened out to a good shoot. Assays have run up to 900 oz. in silver.

Trail.—Ore receipts at the smelter for the week ended August 21 totaled 8244 tons, 7940 tons coming from the company's mines. The custom shippers were: Chambers, Sandon, 7 tons; Last Chance, Sandon, 26; Providence, Greenwood, 41; Republic, Republic, 36; Surprise, Republic, 155; Rosebery-Surprise, Rosebery, 38; and Nugget, Sheep Creek, $\frac{1}{2}$ ton.

KOREA

Unsan.—The report of the Oriental Consolidated Mining Co., for the month of June, shows that 160 stamps ran 25.02 days, crushing 18,820 tons of ore. The gross receipts for the month were \$95,191; operating costs, \$82,963; operating profit for the month, \$12,228. There was put back into development work \$1803, leaving a net profit over all expenditures amounting to \$10,424.

MEXICO

Chihuahua.—The Guadalupe group of eight claims, situated in the San Juan mountains of the district of Allende, has been filed on by Julian Sanchez and Juan Aceves, of Chihuahua City. The properties are traversed by some well-defined veins which give good assays in silver, gold, lead, and copper on the surface.

E. A. Reilly and associates of Chihuahua have applied for titles to a group of 20 claims situated in the Lobos mountains near the station of Jiminez. The new location is surrounded by a number of old producing mines, among which are the Romeo, Maria, Centenario, and La Soledad. The ores of this district are principally gold.

M. G. Garner is surveying some recent locations recorded by Jose D. Cruz in the district of Andes del Rio. The survey will embrace the old Santa Maria mines which formerly belonged to Guadalupe Loyo and abandoned during the revolution.

Durango.—Fernando M. Ortiz, of Parral, has applied for new titles to the Sierpe, La Noche, La Aurora, and Elenita mines in the Inde district of this State. These properties were recently declared open for re-location, having been forfeited by neglect of the former owners to pay the taxes. There are a number of old workings which have filled with water. Some of the mines formerly produced good ore and as soon as the old shafts are cleaned out it is expected that shipments will be resumed by the new owner.

The Gran Bonanza mine, in the Ocampo district of the State of Durango, has been forfeited and is to be re-located by H. C. Nieli, well known mining man of this district and Parral.

Herbert E. Hambleton, an English mining man in the Guanacevi camp, has added seven new claims to the Culebra

and La Verde groups, to be patented under the name of Ampliacion de la Culebra. The survey is being made by Kenneth A. G. Shearer and embraces an extension of some of the principal veins which travers the old claims and which produce a good grade of silver-lead ore.

G. S. Betancourt has discovered a silver-bearing vein in the Animas mountains of the Tamazula district. He is having a survey made of four claims which have been recorded under the name of La Valenciana.

Guanajuato.—A number of the silver mines of Guanajuato and Aguascalientes have suspended operations due to the low price of silver. Among the principal producers which are closed down are the Anguanguero and Zitacuaro. El Favor mine, one of the big silver producers of the State of Jalisco, has suspended operations, discharging a large number of miners and outside workmen.

ONTARIO

Cobalt.—With a force of 105 men, the Conlagas mills are

Keno Hill, Mayo District, Yukon Territory

handling 700 tons of ore daily. This is made up of 370 tons from underground, the remainder being old tailing. Production from 2000 tons treated during July reached nearly 200,000 oz. of silver.—The price of Cassel cyanide has been reduced to 19c. per pound from the high point of 21c. during the past two years.

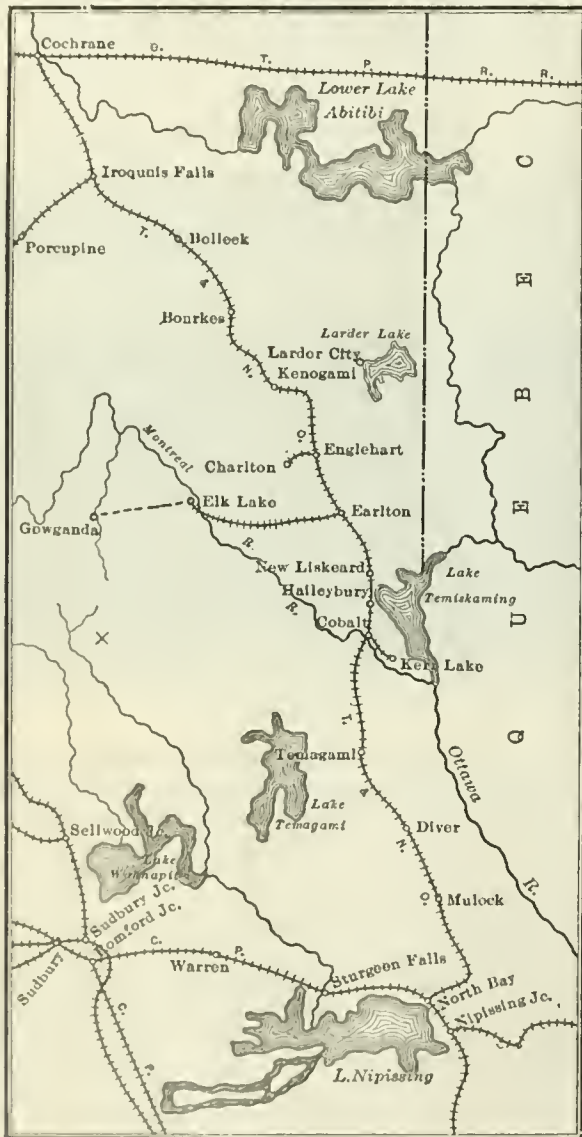

Sandy McIntyre, who discovered the Temiskaming mine fifteen years ago, as well as staking the McIntyre-Porcupine in 1909 and making the first discovery of ore on the Teck-Hughes mine in 1910, has just made another promising gold discovery in the township of Gauthier, in the eastern part of the Kirkland Lake field. The Temiskaming has produced an aggregate of 12,000,000 oz. of silver to date while the McIntyre is producing over \$2,000,000 per year and with \$400,000 per year from the Teck-Hughes. In each case McIntyre sold out at a comparatively small price.

Kirkland Lake.—Another new vein has been opened up on the King-Kirkland which carries ore at the surface over a length of 200 ft., the paystreak being from one to two feet wide.—Structural work on the new mill of the Ontario Kirkland will be completed in about a month. The machinery is arriving and it is hoped to have the mill in operation by the end of the year. A quantity of ore averaging about \$15 gold per ton is in readiness for milling.

Larder Lake.—The Canadian Associated Goldfields has decided to cease operations at Block B (formerly the Harris-Maxwell), where nearly 100 men are employed, in order to concentrate their efforts on Block C and D. Cross-cutting is

under way at the 175- and 300-ft. levels and the shaft is being deepened.

Porcupine.—Shareholders of the Davidson Consolidated, at a meeting held in Toronto on August 24, ratified the sale of the assets of the company to a British syndicate, which will organize a new company to be known as the Porcupine Davidson Gold Mines, capitalized at £1,000,000. Shareholders of the old company retain their securities, and the price paid for the assets is £175,000 preferred stock and £450,000 common stock in the new company and £50,000 cash. A sum of £200,000 is to be set apart for working capital. Unwatering of the mine has already been commenced preparatory to the resumption of operations.

Northern Ontario

Sudbury.—The nickel-mining industry continues inactive and owing to the dullness of the market appears likely to remain so for some time. The International Nickel Co. is operating on a limited scale and is not expected to increase its output before the completion of a new steel plant, which is being erected in the United States.—The Mond plant is merely marking time and it is understood that active operations will not be resumed until exchange conditions are more favorable.—Although an official visit was made to the plant of the British America Nickel Corporation about six weeks ago, no announcement as to the intentions of the company has been made.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

L. W. Storm, of Seattle, is at Great Falls, Montana.

F. Dean Bradley has moved from Goldfield to Tonopah.

K. F. Klein has returned to New York from Alma, Colorado.

Joseph Irving has returned from Jerome to Bisbee, Arizona.

R. V. Thurston, of Payette, Idaho, is at Knoxville, Tennessee.

J. A. McRae is visiting the mining districts of northern Manitoba.

J. F. Callbreath was at Denver last week, on his way to Washington.

Roscoe Edyvean has moved from Bishop, California, to Tonopah, Nevada.

F. E. Calkins has been examining mining properties near Crown King, Arizona.

Walter H. Aldridge has moved his office to 41 East Forty-Second St., New York.

Fred T. Newport has moved from Searchlight, Nevada, to Laguna Beach, California.

S. Paul Lindau is examining mines in the Katherine and Walker districts of Arizona.

A. E. Roberts, recently in Venezuela, is now in San Francisco on his way to New York.

Arthur W. Jenks is in New York. He is expected to return to Berkeley early in October.

W. S. Boyd, manager for the Ray Consolidated Copper Co., at Hayden, Arizona, is at Salt Lake City.

Eugene C. Koenig, superintendent for the Silver Gulch M. & M. Co., at Dunton, Colorado, is at Milwaukee.

Edward N. Greenleaf has been appointed manager for the Allis-Chalmers Manufacturing Co. at Salt Lake City.

Roy Hatch, superintendent of the Arthur plant for the Utah Copper Co., has been in the Yellowstone Park.

J. G. Reilly, superintendent for the Peregrina M. & M. Co., at Guanajuato, Mexico, is at St. Louis, Missouri.

Horace V. Winchell has moved his headquarters from Minneapolis to 1116 Pacific Mutual Bldg., Los Angeles.

F. J. Nagel, mining engineer for the Cia. Minerales y Metales, at Monterrey, Nuevo Leon, Mexico, is at Denver.

W. W. Wishon has just completed an examination of the Henry Ford group of claims in the Oatman district of Arizona.

F. W. Gray has resigned the editorship of the 'Canadian Mining Journal' to join the staff of the British Empire Steel Corporation at Montreal.

H. E. Nyberg, formerly assistant general manager for the Cia. Minera Las Dos Estrellas, of El Oro, Mexico, has been appointed general manager.

William T. MacDonald has returned to Salt Lake City from a trip to south-eastern Utah, where he made an examination of the oilfields in San Juan county.

George T. Hansen, for ten years manager for the Allis-Chalmers Manufacturing Co. at Salt Lake City, has resigned. He will return to his practice as a mining engineer.

R. G. Hall is retiring as general manager for the Burma Corporation, and is to be succeeded by P. E. Marmion, lately manager for the Swansea Vale Spelter Company, in South Wales.

G. W. Crane, for several years geologist to the Chief Consolidated Mining Co., has opened an office as consulting geologist at Salt Lake City. He will continue to be associated with the Chief Consolidated company.

EASTERN METAL MARKET

(By wire from New York)

September 5.—Copper is quiet and firmer. Lead is quiet and higher. Zinc is more active and steadier.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

FUTURE OF THE AUTOMOBILE

A thorough painstaking investigation into the present and future status of the automobile industry has just been made by Leonard P. Ayres, vice-president of the Cleveland Trust Co. Many of Ayres' conclusions are rather startling. For example, he found that the capacity of the automobile factories in this country was more than 1,000,000 cars per year in excess of the present demand. If these factories were run at their full capacity for a few years they would soon supply every potential buyer in the United States. There would be so many automobiles in use that the gasoline supply would be inadequate, and some other kind of motive power would have to be developed.

Although the population of the country is about 105,000,000, the greatest number of possible automobile buyers, even by a liberal estimate, is less than 20,000,000. The figure of 20,000,000 is about the number of white American families. It is also the number of persons whose occupations and earning power are such that they might buy automobiles. Not every man who has the price of an automobile will buy one. It seems altogether doubtful if the sale of the higher-priced cars will ever be much more than it is now. Since 1916, the increases in the annual output of automobiles have been largely accounted for by the mounting number of Fords and other less expensive makes. Ayres believes that for several years new users of cars will be confined largely to people of limited means who will buy these less costly machines.

Computations have been made to discover the number of cars in use each year in each division of the country for every 100 native white men above the age of 21, for it is believed that this is a safer basis for estimating possible future domestic markets than most of the others that have been used. The results are presented in the following table:

Division	1912	1916	1920
New England	7	20	42
North Atlantic	5	15	34
East North Central	5	19	45
West North Central	5	25	57
South Atlantic	3	10	35
East South Central	1	7	22
West South Central	3	15	39
Mountain	3	16	45
Pacific	7	24	60
United States	5	17	42

The important fact revealed by these figures is that the number of potential purchasers in this country who are still unsupplied with cars is much smaller than has generally been supposed. Another significant fact is that the use of this criterion for computing the probable limits of the domestic market gives results that vary much less between the different sections of the country than do the figures based merely on the relationship between the number of people and the cars in use. The outcome appears to be, then, that competition between manufacturing establishments will be sharper than ever, and prices of automobiles will eventually be much lower.

MONEY AND EXCHANGE

Foreign quotations on September 6 are as follows:

Sterling, dollars:	Cable	3.71
	Demand	3.72
Franc, cents:	Cable	7.07
	Demand	7.69
Lira, cents:	Demand	4.36
Marks, cents:		1.12

Eastern Metal Market

New York, August 31.

Developments are meagre and demand for most of the metals is light.

Copper has sold at lower levels, but is a little stronger again.

Sales of tin have been good in the aggregate; prices are firm.

The lead market is quiet and steady.

Demand for zinc is very light and prices are lower.

Antimony is quiet and unchanged.

IRON AND STEEL

In the varying reports from different branches of the steel industry the balance is still on the side of betterment in demand, but with no clear indication of progressive improvement ahead, says 'The Iron Age'. Exhaustion of inventories is more marked; this is the occasion of buying. Steel Corporation activities still average a fraction under 30%.

The competitive aspect of the market has not changed, despite widespread reports attributing a more aggressive policy to the leading producer. Actual transactions show that both the Steel Corporation and the leading independent producers are following their practice of many weeks, making such concessions as are required by new developments. The one formal price change of the week was the general dropping to 2.75c. from 4c. on galvanized sheets.

The volume of fabricated steel, which has been a continuing feature in demand, has been large enough to afford tests of price-strength. Tonnage contracts have been written at less than the quoted market. Besides additional orders for car-repair, orders for about 7500 tons of structural material has been closed and 11,000 tons added to what is pending.

Export trade has been better in some directions. Japan is still a steady buyer of black sheets, which are galvanized there. Japan also has bought considerable amounts of sulphate of ammonia from coke by-product plants.

The extent of the decline in steel prices is indicated by 'The Iron Age' composite, which at 2.293c. per pound for finished steel products is now 36% above the ten-year pre-war average, though it was nearly 55% above this pre-war average only two months ago.

COPPER

If sellers were willing to meet the ideas as to prices of prospective buyers as indicated by the number of inquiries, a fairly active buying movement would probably result. Bids by such inquirers are, however, below the quotations of most sellers and nearly all the large producers are out of the market at present levels. Electrolytic copper has sold as low as 11.37½c., but all metal as cheap as this has been sold. The prevailing quotation now is 11.62½c., New York, or 11.87½c., delivered, though perhaps in one or two quarters 11.75c., delivered, could be done. Prospective demand is regarded as good as soon as a definite basis is settled or the bottom of the market for all sellers is reached. Demand which resulted in actual buying is light and foreign sales are not heavy. The Lake copper market is nominal at about 12 to 12.25c., delivered.

TIN

The market is moderately active and firm to higher. For some weeks the price of spot Straits, New York, has held close to 26c., at which level buying has been good in the aggregate. This is true of last week, though yesterday and Monday buying was very light. On each day last week moderate sales were reported, so that the total for the week

was of fair proportions. There were certain days when some sellers appeared eager to dispose of their tin. In the business done last week two importers were the principal sellers, with dealers and consumers the buyers. It is stated that one consumer bought 1000 tons direct from the Far East. Prices yesterday were 26.75c., New York, for spot Straits, with London quotations at £156 10s. for spot standard, £158 15s. for future standard, and £157 5s. for spot Straits. Arrivals thus far this month have been 2500 tons, with 3340 tons afloat.

LEAD

Both the leading producers and independent sellers report a good business of moderate proportions at the prevailing prices. The leading interest continues to quote 4.40c., New York, and St. Louis, while the outside market is quoted at 4.40c., New York, or 4.20c., St. Louis, at which levels business is being done. There are no developments of interest, lead being regarded as the strongest of the non-ferrous markets.

ZINC

No improvement is apparent and prices for prime Western continue to drop. Sales have been made as low as 4.12½c., St. Louis, or 4.62½c., New York, which we quote as the market. There are one or two interests which seem to offer the 'market' and there is not enough supporting demand to offset this weakness.

ANTIMONY

In a very quiet but dull market wholesale lots for early delivery are unchanged at 4.50c., New York, duty paid.

ALUMINUM

The leading maker continues to quote 24.50c. per pound, f.o.b. plant, for wholesale lots for early delivery, while importers ask 19 to 20c., New York, for the same grade.

ORES

Tungsten: The situation is unchanged, with quotations ranging from \$3 up per unit, depending on the grade and the delivery.

Ferro-tungsten is quoted at 48 to 58c. per pound of contained tungsten in lump form, guaranteed as to quality.

Molybdenum: Quotations are unchanged at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: High-grade manganese ore can be bought as low as 20c. per unit, seaboard, but there is no demand. Stocks in the country are heavy.

Manganese-Iron Alloys: An inquiry for 100 tons of ferro-manganese is the feature of a market in which demand is light and quotations firm at \$65, seaboard, for the British alloy and \$70, delivered, for the domestic. An inquiry for 350 tons of spiegeleisen is the only one of consequence in a dull market where quotations range from \$25 to \$27, furnace.

Price deflation has been as drastic in petroleum as in any other large industry, but in recent weeks steadiness has been marked in the general price structure. Prices for crude have declined from 30% in California to 71% in Mid-Continent field, the latter representing 60% of domestic production. Gasoline prices are down 30% from the high of 1920. Kerosene, lubricant, and fuel-oil prices show extreme declines. Demand for fuel-oil for shipping has increased this year over last. Industrial use of oil products, especially lubricants and fuel-oil, has remained low; the market for the latter still remains weak.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

AN IMPROVED PORTABLE COMPRESSOR

The accompanying illustration shows a gasoline-driven portable air-compressor, Class P2-DGL, manufactured by the Chicago Pneumatic Tool Co.

Recognizing the demand for a particularly light machine of this kind, the company has developed a compressor ideally meeting these requirements. A study of the construction of this new compressor will indicate that everything possible has been done to create a unit combining large capacity with light weight, plus a simplicity which removes the need for a specially-trained operator. Although compact and very light in weight, this new unit is built of highest quality materials. It is presented with the assurance that it will give the same full measure of satisfaction that has charac-

Chicago Pneumatic Tool Co.'s Improved Portable Compressor

terized the company's older types of portable air-power plants. The compressor is of the two-cylinder single-acting vertical type. The cylinders are cast en-bloc and are entirely water-jacketed. They are fitted with 'simplate' flat-disc inlet and discharge valves which, together with the low clearance, account for the high efficiency obtained. The crank-case is completely enclosed and is provided with large openings for inspection, cleaning, or adjustment. The bearings, which are cast integral with the crank-case, are accessible and can be easily adjusted by means of liners. Baffles are provided to prevent an excess of oil from working above the pistons into the cylinders.

The crank-shaft is of the best grade of open-hearth steel, forged by hand. The connecting-rod is a drop-forging, also of open-hearth steel. It has a solid eye, brass-bushed at the piston-end, and an adjustable babbitt-bushed eye at the crank-end. The differential unloader is positive and dependable in its operation. When it operates it admits air from the receiver to a small plunger in each inlet-valve, holding the valves open and allowing the air in the cylinder to return to the atmosphere.

The air-compressor is direct connected to a tractor-marine gasoline engine of the four-stroke-cycle, four-cylinder type, equipped with a high-tension magneto, a water-circulating

pump, a force-feed lubricator, a specially-designed governor, and a muffler. No battery is required—the engine starts on the magneto. A ratchet hand-lever is furnished for starting.

The fuel-tank, which is of galvanized iron, has a capacity of 20 gal., and is suspended from the canopy top, permitting positive gravity-feed of the gasoline at all times.

The speed of the engine is controlled by the auto-pneumatic throttle, an exclusive feature, which, working in conjunction with the engine-governor and the differential unloader of the compressor, throttles down the speed of the engine when the compressor is unloaded and thus saves fuel and lubricant, and also allows the circulating water to increase its cooling effect. When the pressure of air in the receiver drops and the compressor resumes its work, the auto-pneumatic throttle instantly speeds up the engine to normal speed, much after the manner of the accelerator of an automobile.

The compressor and the engine-shaft are connected by means of a high-grade flexible coupling, which compensates for any irregularity in the alignment of the two shafts and for unequal wear of the compressor and engine bearings, and also serves as a fly-wheel. The fly-wheel is designed to produce the proper inertia effect without adding unnecessary weight. Its rim is marked to aid the operator in re-timing the gasoline-engine valves if they should ever require adjustment.

Thorough cooling of the compressor and engine is effected by a positive and reliable system. Two centrifugal circulating-water pumps, one driven from the magneto shaft and the other belted to the compressor crank-shaft, force water through jackets of liberal size and through a large radiator, which is cooled by a powerful fan belted directly to the engine-shaft.

A receiver of large capacity is mounted directly on the truck and is equipped with safety-valve, drain-valve, discharge-valve, and pressure-gauge.

The entire equipment is firmly mounted upon an all-steel truck, having a steel-plate canopy top and sheet-steel sides which completely enclose the outfit. The sides can be locked in place. The frame of the truck is made of heavy 8-in. steel channels. The front wheels are 28 in. and the rear wheels 30 in. diameter; all wheels are 6 in. wide. The tread is 4 ft. 8 in. Two clamps are provided for clamping the channels to the front axle so as to reduce vibration. The outfit is furnished complete with tongue, single- and double-trees, and a reliable hand brake.

BUY SOMETHING MADE OF COPPER

A letter signed by J. L. Harmon, manager for the Mine & Smelter Supply Co. at El Paso, says in part:

"To the Boosters of the South-West:

"Here is a big idea we all should put over:

" 'Buy Something Made of COPPER'.

"Every one of us in the great South-West either directly or indirectly owe a great amount of our bread and butter to the copper industry.

"Now that the copper market is dull it is just the time

for all of us to pitch in and enliven the trade. We can make a demand for this product if you will lend a hand.

"Here are a few ideas:

"Stamp your outgoing letters 'Buy Something Made of COPPER'. A rubber stamp will do.

"In your advertisements insert 'Buy Something Made of Copper'.

"Put cards in your windows, 'Buy Something Made of Copper'.

"Display copper wares in your windows. Make attractive and original counters in your store. Electrical dealers have a great opportunity to boost the game. Here's where the ball starts rolling. Make everybody read, say, or think 'Buy Something Made of Copper'."

COMMERCIAL PARAGRAPHS

The American Steel & Wire Co. has appointed H. S. Durant as sales agent, and M. W. Floto as assistant sales agent, at its Detroit office, to succeed M. Whaling and T. J. Usher Jr.

Edgar L. Keithley has established an office at 1323 Alaska Bdg., Seattle, Washington, as a representative of the Central Foundry Co., makers of Universal cast-iron pipe, soil-pipe, and general castings.

The Pittsburgh Instrument & Machine Co. has issued an attractive illustrated catalogue entitled 'Engineers' and Surveyors' Instruments and Accessories'. A complete line of such equipment is manufactured by the firm at its factory and laboratories at 40 Water St., in Pittsburgh, Pennsylvania.

George T. Hansen has terminated his connection as district manager for the Allis-Chalmers Manufacturing Co. at Salt Lake City, effective September 15. He will engage in his personal mining and oil enterprises and will handle rubber-lined sand-pumps which have been patented by him and licensed to the Allis-Chalmers company and to the Byron Jackson Iron Works.

'Short Cuts to Power Transmission' is a neat little publication prepared by the Flexible Steel Lacing Co. No one who reads it can fail to pick up many valuable points regarding belting and belt-lacing. The publishers seem willing to let good-will accrue toward their product from the reader's appreciation of their efforts to help him, rather than devoting an unusual amount of space to their Alligator steel belt lacing. Copies may be had by addressing the Flexible Steel Lacing Co., 4653 Lexington St., Chicago.

The Dodge Sales & Engineering Co., of Mishawaka, Indiana, announces that the excavation for its new \$1,000,000 building in New York City, at 49 Park Place, is practically completed. The new building will occupy 165 ft. on West Broadway, 50 ft. on Murray street, and 75 ft. on Park Place. Present plans call for twelve stories, but foundation and construction will permit of an additional four stories if needed. The basement of the building and part of the first three floors will be used by the Dodge Sales & Engineering Co. as a warehouse, and for the sales and distribution of Dodge, Onelda, and Keystone products for the mechanical transmission of power, covering both domestic and export needs. The products of the Dodge Sales & Engineering Co. include pulleys, rope-drives, hangers, shafting, bearing, couplings, and heavy oil-engines, and are all distributed, in the main, through six hundred dealers who draw from the various branches of the organization situated in nearly every large city in the United States.

E. I. du Pont de Nemours & Co. has just issued a folder describing in detail the qualities of 'Minefab', its new covering for concentrating tables. The du Pont company is, of course, well known as having manufactured for more than a hundred years explosives for mining purposes, but it is also an important maker of coated fabrics. This work

has involved the development of a large number of special fabrics for varied industrial uses and has led to the production of 'Minefab'. 'Minefab' is described as a specially treated fabric of great tensile strength, made permanently impervious and flexible by the thorough impregnation of both its surfaces with a non-deteriorating waterproof compound, highly resistant to chemical action and to abrasion. It is stated to be the only material ever made for the specific purpose of covering concentrator tables. A long period of service tests which gave the most satisfactory results have led the company to recommend it as thoroughly satisfactory for the treatment of all ores.

'Duroloid' grinding-balls are a superior type of grinding-ball, cast from an alloy of steel with a base of white iron which contains a high percentage of combined carbon. The high-carbon content of the iron used in manufacturing 'Duroloids' produces such an extreme degree of hardness that it is almost impossible to scratch one of them with a steel tool. This quality of extreme hardness makes 'Duroloids' the ideal medium for reducing ore to any degree of fineness. 'Duroloids' are cast in such a way that the iron crystals radiate from the cores of the balls; thus, only the ends of the crystals are exposed, wear is reduced to a minimum, and chipping becomes impossible. Each ball is tested by hand for hardness and defects before it leaves the manufacturer, thus assuring the purchaser perfect balls in every case. A daily analysis of 'Duroloid' metal keeps the quality of the balls absolutely uniform. 'Duroloids' are made in sizes ranging from $\frac{1}{2}$ in. to 3 in. diameter. They are made by the Los Angeles Foundry Co., at Los Angeles, California.

The Allis-Chalmers Manufacturing Co. has issued a new bulletin, 1106A, entitled 'Type 'E' Direct-Current Motors'. This new line of motors has been designed for belted as well as direct-connected applications and is particularly suited to exacting requirements. It is a complete new line throughout, no attempt having been made to re-design old apparatus or to employ parts from any previous machines. The new Type 'E' motors incorporate the latest and best features of direct-current engineering practice and are backed by nearly thirty years experience in the design, construction, and commercial application of motors for practically every industry. Among the important features are the following: Ratings and speeds corresponding to standard 60-cycle induction motors; a complete line of constant and adjustable speed-ratings; rugged cast-steel yokes; commutating poles, ensuring sparkless commutation; dust-proof bearings; windings treated to resist oil and moisture; thorough ventilation; conduit boxes on all motors; improved box-type brush-holders; standard enclosing covers; interchangeable parts; and all parts easily accessible.

An all-steel chassis, low over-all height of the body (60 in.), and heavy duty Hyatt high-speed roller-bearings are distinguishing features of the new Miami slow-speed tractor-drawn trailer manufactured by the Miami Trailer Co., of Troy, Ohio. The tractor-drawn reversible hauling-trailer has demonstrated that under many conditions it will deliver material at a lower cost per ton-mile than any other equipment. In this new trailer the Miami company claims to come nearer to realizing full efficiency from this type of hauling-equipment than any other manufacturer has yet attained. The chassis frame is made of 6-in. channel-steel, securely riveted at corners and cross-members, using heavy corner irons and angle reinforcements. Hyatt bearings are protected on the inside and outside by dust-collars, and are adjusted for end-thrust. The Alemite system of lubrication is employed. Every bearing is equipped with Alemite grease nipples and each train of wagons is provided with an Alemite grease-gun. A train of six wagons can be lubricated by one person in from 10 to 15 minutes, ensuring perfect lubrication to every part.

T. A. RICKARD, . . . Editor

DISPATCHES from Australia announce two gold rushes, one to the Hampton Plains district of Western Australia and the other to Glen Innes in New South Wales. Details are lacking. We hope the discovery may prove important, for nothing would give a better fillip to mining than the development of one or two new districts.

WE were asked the other day how much copper is being produced by the mines in Central Africa controlled by Belgian and British capital, the fear being intimated that the production from that source might prove a menace to the American market. In June the Union Minière du Haut Katanga, owning the Tanganyika copper deposits, made its record output, namely, 3189 tons of metal.

THIRTY-THREE foreign countries imported machinery from the United States during the month of July; the purchases of 13 of these exceeded \$5000 each, according to a statement recently issued by the Department of Commerce. Each of 11 others spent more than \$5000 for oil-well machinery, which, according to the arbitrary classification of the Department, is summarized separately. This makes 24 different countries, scattered in every continent, that did more than a nominal business with manufacturers of this kind of machinery in the United States during that particular month. July was in no way exceptional, and doubtless the records for a year would show highly profitable dealings with 50 foreign countries. These data indicate the widespread appreciation and use of American-made machinery in every part of the world.

GENERAL PERSHING'S rebuke to Mr. Samuel Gompers will have been read approvingly by many thoughtful citizens. It was poor taste on the part of the president of the American Federation of Labor to use the Lafayette-Marne celebration as an occasion for glorifying his monster union and claiming that it played a decisive part in winning the War. The men who won the War are lying in their graves scattered over more than half of Europe, not to mention Asia Minor and the seven seas. We agree with the General that it is about time to say "that America shall be governed and ruled by American citizens, and not by this organization or that organization, which may have selfish purposes to serve".

That includes not only the American Federation of Labor but the anthracite trust, the beef trust, and the powder trust. For our own part we consider that the good work done by organized labor during the War is overshadowed by the unholy profiteering in which it indulged at the expense of the country during a great crisis.

IN regard to the required payment of \$50 per acre in lieu of assessment work, as specified in the Bill to amend and codify the United States mining laws, we are informed that this provision was made for the following reasons: Under the present law a discovery of valuable mineral is an essential prerequisite to the validity of a mining location. Under the proposed new law, however, claims may be located without discovery and held for five years by the performance of labor annually to the amount of \$5 per acre or the annual payment in cash of \$5 per acre. In drafting the proposed law it was thought that locators ordinarily should not be permitted to hold claims without a discovery for a period longer than five years. With the idea, however, that there might be cases, for instance, of valuable improvements having been placed upon the locations, which claimants therefore might desire to hold beyond the period of five years, it was provided that they might do so upon the payment of \$50 per acre annually. This heavy annual assessment was fixed with the idea of discouraging the holding of mining claims without a discovery beyond the period of five years; at the same time it was designed to avoid the incidence of possible hardship under special circumstances, at the termination of the five-year period.

MANY of our readers have doubtless received 'literature' from a genial gentleman who points the way to a substantial fortune by the investment of a few dollars in companies that control sundry portions of the expansive surface of western Texas, beneath which there is a "chance" of finding valuable deposits of potash. The inference of the promoters is that the chance is excellent; we venture to surmise that, in any specific area, it ranges from highly improbable to remotely possible. Perhaps we are pessimistic. The U. S. Geological Survey, in co-operation with the Bureau of Geology at the University of Texas, has been investigating for several years the possibility of developing valuable deposits in the 'Red bed' region of western Texas and parts of adjoining States. The principal source of information

has been the work of oil-well drillers, some of whom, in a rather haphazard manner, have preserved samples of the sludge from their drill-holes. Several of these were found to contain potash in proportion as high as 9%. At the time these samples were taken, the holes were from 1600 to 2425 feet deep and the most widely separated of the three principal wells were 125 miles apart. The Government geologists warn the public that the conditions of drilling and sampling at all three points are unsatisfactory, and that it remains to be seen whether the beds that are rich in potash are thick enough to justify mining with any hope of profit. They declare, however, that the indications are sufficiently encouraging to warrant thorough testing with core-drills, principally because of the tremendous importance to the whole United States of proving the existence of workable deposits of potash.

INTROSPECTION is good for any of us. The article by Mr. Edwin Higgins that appears in this issue should prompt at least one man in every mine organization to analyze himself and his job. It contains germs of thought that may be cultivated profitably by the technical men who specify the materials and supplies that are required for the operation of mines and reduction plants, but it is the purchasing agent, in particular, who should be stimulated to make a searching examination of his own temperament, his own methods, and his own attitude toward his work. As Mr. Higgins says, the "successful purchasing agent must have most of the virtues known to man and none of his defects". We venture to suggest a few principles that Mr. Higgins does not emphasize, but that may well guide the man whose business is to buy. He should obtain exactly what is specified by the superintendent or foreman who is to use the material; something else may be just as good or even better, but the wise purchasing agent will buy according to the requisition; his duty is to obtain the best possible price, not to select the kind of machine or material to use. This does not mean that he should not give the superintendent the benefit of any information that he may obtain regarding other products; but rather that he should leave the question of preference to the man who must get results from using the things purchased. A successful purchasing agent will make business friends of the salesmen with whom he deals. They usually know more about their particular 'line' than he does, and their goodwill is a great asset, just as their dislike may easily prove to be disastrous. An illustration is seen in the following experience of a purchasing agent who was overbearing and arrogant in his dealings with the salesmen who sought his business. He was generally hated by all of them for this attitude and for his belief that he knew the technical details of their business as well as they. He received a requisition for several miles of copper wire "or its equivalent in electrical-carrying capacity of aluminum wire". His duty to his employer, obviously, was to purchase whichever material was cheaper, provided it would do the required work. After obtaining

quotations on both materials from a number of firms, he purchased the copper wire as being, so he thought, the more economical. It happened that, with the price of copper prevailing at the time, aluminum would have been much cheaper for the particular purpose for which this wire was to be used. He had taken into consideration the difference in conductive capacity of the two metals but had neglected to allow for the difference in specific gravity, which was an essential point because the quotations were given in cents per pound. Four different salesmen deliberately had let him fall into the error because of the resentment they cherished against him. The company wasted several thousand dollars; the upshot was that a little later the purchasing agent lost his job. A wide detailed knowledge of commodities and machines and supplies is desirable, but, as in most spheres of life, a sympathetic understanding of human nature and a decent treatment of the men with whom one comes in contact will go a long way toward compensating for a lack of technical information; they are *the* essential assets of a good purchasing agent.

STATISTICS published by the newly-formed Division of Electrical Machinery of the Department of Commerce indicate the growing importance of one of the principal branches of our export trade. For the fiscal year 1914-1915 the exports of electrical machinery and appliances amounted to \$19,722,000. For the fiscal year 1917-1918 they had advanced to \$54,547,000; for 1918-1919, to \$80,000,000; for 1919-1920, to \$87,000,000; for 1920-1921, to \$119,221,000. This increase is all the more significant because it is much greater than that which occurred in any other division of machinery exports. Further, the actual amount exported during the last period cannot be gauged by the value; for prices in many instances were less than they were during the previous period. Electric lamps were exported to all parts of the world; telephones valued at over \$6,000,000 went to over 60 different countries; 88,000 electric-fans were distributed among more than 70 countries; electric heating and cooking apparatus went to over 50 countries and colonies. The electric-motors exported were valued at over \$18,000,000; the dynamos and generators, at about \$17,000,000; and the insulating wires and cables, at over \$11,000,000. The United States is electrifying the world; the demand for electric equipment is an evidence of advancing civilization in other countries. Colossal plants for the utilization of the water-power that is now being wasted in South Africa will soon be considered as essential to the proper progress of that part of the world and for the conservation of the industries that are now on the wane. Other countries will follow suit. Every piece of American electrical machinery that is sent abroad will do missionary work and will help to hasten the coming of the age when the economization of man-power, by the substitution of hydro-electric or steam-electric energy, will be recognized as the height of efficiency. The demand for copper when the electrical age is reached throughout the world will be enormous.

Cost of Mine Supplies

A mining engineer, connected with several small but promising enterprises in California, writes a friendly letter to question the accuracy of a statement made recently in an editorial paragraph in which we expressed the opinion that many idle mines in California soon would resume operations for the reason that "the decline in the cost of supplies and in the rate of wages has improved conditions considerably". The assertion with which he takes issue is that relating to the reduction in the cost of supplies, although he confesses that he is not so sure of his ground as to wish his letter published. For that reason, also, we refrain from mentioning his name. He says: "I believe if you will take the following articles as representative of mine material you will be unable to figure an average reduction of 5% during the year: machine-drills and parts, carbide, blacksmith's coal, drill-steel, oil, packing, mine-cars, rail, pipe, powder, fuse, and caps. On the first seven articles mentioned I do not believe there has been any reduction in price". He then suggests that we print "a short list of materials showing the percentage of increase or decrease in the price of each". Although the statement to which our correspondent refers was general, it was based on definite information, as will appear from an inspection of the following specific comparisons, in which are included not only the items that he has listed but some others that indicate the downward trend. Nearly all these figures were obtained from the purchasing agent for an important group of mines that has its main office in San Francisco; they represent actual purchases made during August 1920 and August 1921 and are accurate.

	August 1920	August 1921	Decrease, %
Rock-drills, a standard sinker.....	\$170.00	\$170.00	0.0
Carbide, per ton	155.00	155.00	0.0
Blacksmith coal, per ton.....	34.00	31.00	8.8
Drill-steel, hollow round, per lb.....	0.19	0.16 1/2	13.2
Fuel-oil, in tank-cars, per bbl.....	2.20	1.60	27.3
Packing, a standard kind, per lb.....	1.05	0.92	12.4
Mine-cars, a standard car.....	189.00	134.50	28.8
Rail, in ton lots, per 100 lb.....	5.00	3.25	35.0
Pipe, black, standard 2 1/2-in.....	41.15	28.20	31.5
Powder, 40% gelatin, ton lots.....	21.25	19.00	10.0
Fuse, standard brand, per M ft.....	18.78	16.60	11.3
Caps, No. 6, per M.....	10.20	8.50	16.6
Mine timbers, Douglas fir.....	30.00	23.00	30.1
Copper wire, weather-proof, per lb.....	0.42 1/2	0.20 1/2	51.8
Wire-rope, plow-steel, 6-19, per ft.....	0.29	0.25	13.7
Rubber belting, a standard brand, per ft....	0.95	0.71	25.2
Average decrease, %			20.11

With respect to rock-drills it may be said that the peak was reached in 1919, when prices averaged about 70% higher than in 1913. As compared with most equipment of similar character the increase was moderate; this fact is advanced by manufacturers as justifying the retention of prices today that are identical with those of 1919 and of 1920; nevertheless we feel safe in predicting that the diminished cost of the alloyed steels and other semi-finished materials and of skilled labor required in the manufacture of rock-drills will result in a lower schedule of prices early in the coming year. Carbide is the only other item that has remained stationary, and blacksmith coal is the only other one in which the drop during the past year has not exceeded 10%. Carbide comes from Sault Ste. Marie, and good blacksmith

coal comes from collieries east of the Mississippi. Obviously, high freight rates are an important factor in determining the prices on the Pacific Coast of these commodities, as well as of other bulky supplies that must be shipped a long distance. We do not mention this as being particularly pertinent to the present discussion; it makes little difference to the mine operator on the Mother Lode, for example, whether the manufacturer or the railroad gets his money; what concerns him is the cost of things delivered at the mine. Some of our friends, however, may not know that carbide is shipped 3000 miles to California. Glancing down the list it will be noted that rail and pipe have been reduced one-third, and that mine-timbers of Douglas fir cost only 64% of what they did. The influence of freight-rates is shown here also; at the mills in Oregon the price for fir, of No. 1 mining grade, is now \$10 as compared with \$23, or considerably less than half that prevailing a year ago. It is a fair assumption that during the next year there will be a general readjustment of railroad rates, which necessarily will be reflected in a reduction in the cost of many commodities. Other economic forces are working toward the same end. We feel justified, not only in reiterating the statement to which our friend took exception, that "the decline in the cost of supplies has improved conditions", but in venturing the prediction that there will be a further decline, with a continued improvement of conditions from the miner's standpoint; and, moreover, that this decline can proceed for some time before there will be any but a wholesome effect on the industrial prosperity of the country at large.

The Disarmament Conference

No more important subject has been presented for the earnest consideration of the present generation, not even during the recent tragic years of the Great War, than the international conference that is to assemble at Washington on the anniversary of the Armistice. The date itself brings suggestions that provoke thoughtful men to sombre retrospect, for the jubilation that marked November 11, 1918, proved premature. The War did not end wars and the Armistice did not bring peace. Instead, several new wars were started and several new controversies were developed. Among these are the "Pacific and Far Eastern problems", to which special reference is made in the note that the President sent to the governments of Britain, France, Italy, Japan, and China, when inviting them to take part in a conference on "the question of limitation of armament".

It is said, by Mr. Mark Sullivan, that "Washington understands the importance of the coming disarmament conference, although it seems the country does not". We are loath to believe this. On the contrary, the signs multiply that the peoples of the earth, not the American people alone, are keenly aware of the tremendous issue that is to be settled next November. Even the Peace Conference at Paris was not more momentous, and if importance is to be measured by definite results we hope fervently that the Washington Conference will prove much

the greater event. One reason why the representatives of the various nations at Paris failed so miserably in effecting a real peace was that they tried to do too much; another was that bitter feelings and jealousies were permitted to come between both the late enemies and the recent allies. Since then the world has suffered a sad disillusionment; the confident hopes of 1919 have burned to ashes; the miscarriage of noble ideals and pious aspirations has taught us a lesson. We realize that the recent horrible war has not put an end to the chances of a further conflagration; on the contrary, it has become clear that in the future it will be impossible for two powers to engage in conflict without dragging the whole of the civilized world into another Armageddon. In the future, war will not be restricted like a fire in a paddock, it will be like a prairie aflame in late summer or a pine forest burning in the path of a hurricane. Another fact is manifest: the cost of preparedness for war, on a scale heretofore thought necessary, cannot be borne by the nations of Europe; the cost is breaking Japan; even a country so rich as the United States feels the burden of it. Our people are irritated by the taxation rendered necessary by the last war, and are beginning to realize what it means to maintain a policy of preparedness for the next. Of the revenue of this country 91% goes to pay for past or future wars; the cost of one battleship represents more money than the entire sum set aside by the Federal government for education. Indeed, the waste of capital is one of the features of warfare on a big scale that we are beginning to appreciate. In future, unless reason prevails, wars will not be contests between professional armies, they will be fights to the death between organized peoples, they will be backed by the entire industrial resources of the countries involved. The loss of life on the battlefield is realized, although not deeply enough; on the other hand, most of us are hardly awake to the industrial loss arising from the withdrawal of young manhood from productive labor, not only during war but during the long period of preparation that precedes actual fighting. Still less is it realized how enormous is the wastage of capital, the destruction of things that have cost years of labor, and that cannot be replaced except by the spending of an equivalent human effort. The devastation done by the German armies in northern France is but a sample of what may be expected, for it is certain that in any future struggle all the checks of civilized convention and all the restraints imposed by decency will be ignored, as they were in the last war, and we may expect that effectiveness will be the sole purpose of the methods and materials employed. Among the probable horrors is the wireless control of aeroplanes loaded with explosives in such quantity and of such violence as to beggar even an imagination fed with the memories of Messines and Vimy or reminiscent of the attacks upon Paris and London—as if duelling were still in fashion and gentlemen were to decide a point of honor by the aid of machine-guns. Indeed the searing thought of the destruction likely to result from another Armageddon is intolerable to any sane mind. The possibility of it

must be removed. We owe it to our children. This is the land of our fathers and of the gallant forefathers who founded it, but it is well to recall the even more pertinent fact that it is the country of our children. We owe it to them that their lives shall not be sacrificed to Moloch. We have another debt also. Did we not tell our young men that the late struggle was to be a war to end wars, and did we not send them forth with that slogan to cheer them in the trenches? They were told they were crusaders fighting to rescue the cross from the heathen; they were the defenders of civilization and the heroes of a new dispensation. Have we fulfilled our part of the agreement? No, not at all. The war that they helped to end has been followed by no sure settlement; by no disarmament; on the contrary, it has been followed by many new clashes, by piratic invasions, by disagreements and bickerings that will prove the precursors of more wars unless the whole matter is taken seriously in hand. The living have broken faith with the dead; it is for the peoples of the earth—for our own in its proud leadership—to remember those who lie in Flanders field and to erect to our own unreturning dead a memorial more glorious than brass and more enduring than granite. The only memorial worthy of them is the fulfilment of the purpose for which they died.

Dwellings in Mining Settlements

The fact that beauty need not always be divorced from utility is evidenced in the plans that were made and carried out for an attractive settlement at Rosita, in the State of Coahuila, Mexico, where the American Smelting & Refining Company operates coal mines and by-product plants. The architectural work was undertaken by Mr. H. E. Skougor, of New York, and an account of the new township is given in a recent issue of 'Coal Age'. Suitable housing was provided for the entire staff, from the general manager to the humblest *peon*. The following houses serve to accommodate a force of 31 Americans and 1173 Mexicans: One manager's residence; eight houses for department heads, accommodating the operating engineer, the chief surgeon, the mine superintendent, the chief accountant, the superintendent of the by-product plant, and the welfare superintendent; 14 houses for division heads, accommodating the master mechanics, the chief draughtsman, the chief electricians, the coal-washery superintendent, and assistant superintendent of the by-product plant, the mine foreman, and the powerhouse engineer; two hotels, one to accommodate 18 single American men, and another for 12 single Mexican men; 10 residences for American married clerks and foremen; 45 houses for Mexican mechanics (married), two families in each; 208 houses for married Mexican miners and laborers, four families in each; and 21 *excusados*. Public buildings included a community centre, theatre, public market, school, hospital, and church. The buildings were constructed of adobe brick, plastered, with wood-shingle roofing.

The community building accommodates the railroad

station, telegraph and post offices, the company's commissary, and a public restaurant and sleeping-rooms. The theatre has a seating capacity for 500; the club for the Mexicans contains a bowling-alley, pool-room, barber-shop, assembly-rooms, and public baths. A Roman Catholic church and a residence for the priest are provided. Schools, hospitals, fire-stations, and offices for a camp manager and a *presidente* complete the township. A feature of the design has been an adherence to the Colonial-Mexican style of architecture. Monotony in appearance has been avoided in those cases in which many houses of the same size were needed by designing them of several different types. The dwellings for miners and laborers, for instance, have the same floor area and general arrangement, but seven distinct types have been adopted. The appearance of the town, to judge from the architect's drawings that accompany the description, is such that the article in question should be consulted by all who are interested in the planning of attractive homes for mine employees.

The subject of suitable dwellings for workers in isolated districts, at home or abroad, is one of general interest, although usually given but scant attention. Few corporations are in the position to engage the services of an engineer and architect for such work; it is seldom that a complete town can be planned at one time. The result is that many mining camps suffer because of the crudity of design of the buildings. There are exceptions, but these are found usually on the properties of the larger and more influential corporations. It is not by any means a question of cost only. Convenient and comfortable dwellings can be constructed from cheap materials; in many places an adobe is made of the residue from the mill, with or without the addition of cement. Attention was drawn, a few years ago, to the feasibility of using rammed earth in the construction of walls for dwellings in mining camps, especially those in isolated districts and in foreign countries. This *pisé de terre*, as it is called, has been found entirely satisfactory, but it has been adopted only to a limited extent in place of the more expensive materials. In Rhodesia, one-third each of ant-heap, soil, and sand are used; the mixture is incorporated with water to form a moldable mass. A set of wooden forms, which can be used to make an almost indefinite number of houses, is erected on the site chosen, and the mixture is thrown in and rammed. Clay, ashes, and clinker have also been used as one or more alternative components of the mixture. Ceilings can be made of the same material, with the aid of small-mesh wire-net. Such construction has been proved to be unusually permanent, even in countries where heavy rainfall is common. The thickness of the walls is usually about 14 inches for a height of about 12 feet, the result being that the buildings are warm in winter and cool in summer. If an engineer with Mr. Skougor's artistic perception could give us some simple designs for standard types of dwellings that could be built by the *pisé de terre* method it is certain that mine managers in isolated localities would welcome an opportunity to combine at-

tractiveness with utility, without sacrificing the economy that must ever be an essential of such outlays.

The Kata-Thermometer

The progress of science indicates a growing appreciation of exactness, a distrust of vague generalities, and a desire to be able to speak accurately on each and every subject. To do this it is realized that quantitative estimations as well as qualitative tests are necessary; and such are usually obtainable only after the scientist has developed the apparatus that is required. The microscope was used, soon after its invention, in support of the fallacy called 'spontaneous generation', but that was due to unscientific interpretation. The ultra-microscope has been of immense value to investigators of colloids and their characteristics. The thermometer and the pyrometer made possible the exact measurement of temperatures. The kata-thermometer permits a scientific estimate to be made of the cooling-power of winds and air currents. It was used first in connection with investigations in factories, and was later adopted for use in the deep mines of the Witwatersrand. Occasional mention of it will be found in technical literature, and it was described at a recent meeting of the Institution of Mining & Metallurgy in connection with the discussion of a paper on deep mining; but many mining engineers know little about the design or construction of the instrument, or appreciate the principles on which it was evolved.

One of the earliest experiments on the effect of cooling, made by Dr. Leonard E. Hill, the physiologist, led to a reversal of many time-honored opinions on ventilation. Eight students were placed in an air-tight chamber of about three cubic metres capacity, in which the movement of air, the degree of humidity, and the temperature could be regulated. Here they were kept until the amount of carbon dioxide present had reached about 4%; at this stage the oxygen in the atmosphere was less than 17%, and the air was of such a composition that it failed to support the combustion of a lighted match. The wet-bulb thermometer showed 83°F., and the dry-bulb thermometer a little more. The men inside the chamber exhibited much distress; their faces were flushed, and their skin and clothes were moist with perspiration. The air within the chamber was then set in motion, and immediate relief was experienced; the pulse dropped from an average of 97 beats to an average of 79, and without any alteration or improvement in the percentage composition of the atmosphere inside the chamber. From a study of the results of such experiments, Mr. H. I. Ireland, in the transactions of the Chemical, Metallurgical and Mining Society of South Africa, summarizes the factors relating to atmospheric conditions, exercise, and rest as follows: (1) Stiffness is due primarily to stagnation—to warmth, humidity, and stillness. For the purpose of utilizing fully the value of air as a restorative it should be provided with considerable cooling-power; the temperature should be reason-

ably low; the air should be dry and in motion. (2) A carbon dioxide content as high as 1% has no appreciably detrimental effect on a person who is resting; it only causes deeper breathing on the part of those who are engaged in muscular effort. (3) There is no evidence to show that exhaled air contains organic toxins. (4) The metabolism of living is facilitated, waste products are removed more easily, general health is improved, and disease is lessened by living and working in cool dry air that is in motion. With an appreciation of the importance of atmospheric cooling-power as a factor of efficiency, health, and comfort, Dr. Hill invented and developed the kata-thermometer. Apparently it was used first in Belfast, during an investigation of the conditions under which the operators worked in weaving-sheds and spinning-mills, where the atmosphere was hot and humid. It was then suggested that the instrument should be made to show relative cooling-power, in units of heat per unit of surface per second. This was done.

The kata-thermometer is a spirit-thermometer with a large bulb at the bottom and a small bulb at the top. The glass tube connecting these bulbs is graduated between 100°F. and 95°F., the mean of which is 36.5°C., which may be taken as the average skin-temperature of the human body. Before a reading is possible the instrument is placed in hot water and the spirit is made to rise into the top bulb; it is then dried and placed in the atmosphere of which a measure of the cooling-power is desired; and the time taken for the spirit to drop from the 100°F. mark to the 95°F. mark is noted. The instrument can be used either wet or dry. In the former case the lower bulb is covered with a fine lace glove, in the same manner as a wet-bulb thermometer, and wetted. When dry, it is cooled by convection and radiation; when wet, by convection, radiation, and evaporation. The difference between the two readings gives the measure of cooling by evaporation. The instrument is now constructed of a standard size, and is tested before and after experimental changes of temperature. A factor number is then determined by taking readings in a chamber that is surrounded by a water-jacket. The temperature of the chamber is read, and the cooling-power is noted; then, by means of a formula, a factor is given to the instrument. For example, in the case of a kata-thermometer with a factor of 488, that takes 100 seconds to cool from 100°F. to 95°F., the cooling-power of the surrounding atmosphere is 100 divided into 488, or 4.8 milliealories per square centimetre per second. The area of glass surface of each instrument differs slightly, hence the need for the factor. Therefore, by means of the kata-thermometer, the measurement of the cooling-power of the atmosphere or of air currents can be recorded in precise terms. The value of this device in the investigation of conditions underground is evident. The inventor has pointed out that the human body is a dynamic organ that consumes food, makes physical effort, and produces heat, the excess of which must be dispersed into the atmosphere. The ordinary thermometer is of little value in indicating what the body requires, because the reading

gives the temperature of the surrounding atmosphere only, and takes no account of air currents. The dry kata-thermometer shows the influence of air currents; the wet kata-thermometer, that of humidity as well. Absolute humidity is of much greater importance, physiologically, than relative humidity, because the air is warmed to the temperature of the skin and lungs by contact, and is saturated with water-vapor at that temperature. Air that is saturated at 0°C. can hold about 5 grammes of water per cubic metre; if saturated at the temperature of the skin it holds about 45 grammes; so that, physiologically speaking, air is dry even if there be a mist, and under such conditions it has great powers of drying and cooling the skin and of evaporating water from the lungs. If the air is saturated at the temperature of the body it has no power to cool by radiation or by convection; neither can it cool by evaporation, by reason of its condition of water-saturation at that temperature. Under such circumstances there is a danger of heat-stroke. When British soldiers were in Mesopotamia they lived in tents in which the temperature rose as high as 130°F. Many died of heat-stroke because their health was undermined by malaria, or by other complaints, and the sweat-glands refused to function. Death was seen to be inevitable from the moment that sweating ceased. Normal perspiration may be likened to the operation of a wet kata-thermometer: the temperature is reduced by the evaporation of water. The condition of the invalid who cannot perspire may be likened to the operation of the dry kata-thermometer: a hot wind warms it still more.

The importance of such an instrument in estimating the cooling-power of the atmosphere in mines has been shown by investigations in South Africa. There seems little doubt that in the near future the study of hygiene on a scientific basis will have progressed so that the maintenance of a 'kata' cooling-power in the atmosphere, by the regulation of temperature, humidity, and velocity of air, will be recognized as a step toward the attainment of a high efficiency among employees. Dr. Hill is wise in his conclusions. He argues that atmospheric conditions should be such that manual laborers would be glad to work in order to keep themselves warm. A gradation in the cooling-power of the atmosphere, according to occupation, has been mentioned. Dr. Hill suggests the following 'kata' indexes as suitable for different classes of work: Sedentary occupation: dry 'kata', 5 to 7; wet 'kata', 16 to 20. Light manual work: dry 'kata', about 8; wet 'kata', about 25. Heavy manual labor: dry 'kata', about 10; wet 'kata', 30 to 35. Such a scheme would be impracticable in many cases, for workers have to perform varying kinds of manual labor in the same atmosphere. Nevertheless, the statement of an ideal condition is useful, even if the ideal be not attainable; in the present instance, it is obvious that the recognition of the value of a mathematical basis of estimation has drawn attention to fundamental factors of health and contentment that otherwise might have been ignored. Thus we are made to recognize our debt to the scientist, to whose investigations and inventions we owe so much.

DISCUSSION

Blue Sky Regulations

The Editor:

Sir—I have read with considerable interest your editorial comment in response to a request for a statement in reply to the telegram from the Utah Securities Commissioner who had appealed to the U. S. Attorney General asking that he take action against the California Commissioner of Corporations for his violation of the Sherman Anti-Trust Act for endeavoring to prevent the sale of Bingham-Galena mining stock in California. I note you say "he has full power to refuse the sale of stock in California and that to hold that every Blue Sky Law is null and void with respect to supervising the sale of issues is a position too puerile and foolish for consideration".

As a constant reader of your paper, I am surprised to see such a statement coming from the Editor. I wonder if he ever thought that the various States of the Union get their powers from the Constitution of the United States, and if he ever took time to read it he would find that no State in the Union, California included, has a right to abrogate the right of contract or grant any privileges or immunities to citizens in the several States (such as brokers or licensees under the Blue Sky law). For your information I will quote Art. 1, Sec. 10, of the Constitution of the United States: "No State shall pass any bill of attainder; *ex post facto* law; or law impairing the obligation of contract"; Art. 4, Sec. 2: "The citizens of each State shall be entitled to all the privileges and immunities of the citizens in the several States"; Art. 6, Sec. 2: "The Constitution and the laws of the United States which shall be made in pursuance thereof,—shall be the supreme law of the land and the judges in every State shall be bound thereby, anything in the constitution or laws of any State to the contrary notwithstanding."

Again in Art. 4, Sec. 3: "The Senators and Representatives—the members of the several State legislatures, and all executive and judicial officers of both the United States and of the several States shall be bound by oath or affirmation to support the Constitution". It is evident the founders of our Government, with commendable foresight, were able to apprehend and forestall the imminent dangers from the possible abuse of legislative powers, erecting impregnable barriers by putting into the Constitution certain basic laws, with provision that neither the Congress nor State legislatures shall have the power to contravene, repeal, or abridge them. The Constitution thus established a boundary line between the un-

stable legislative privileges possible to a corporation, and the inalienable rights of individuals under the law. Just the thing the Utah Commissioner is trying to defend for which he is to be highly commended.

Therefore, it is self-evident that the Utah State Commissioner was absolutely right in stating that the State of California had no right to deny a right granted by the State of Utah; and if it were carried before the U. S. Supreme Court it would be proven that every Blue Sky law is unconstitutional and therefore null and void because it does impair the obligations of contract. Then why try to defend this Blue Sky law bunk, which is so damaging to the mining industry?

ROY M. HARROP.

Omaha, August 19.

[Our correspondent is in error; the statement he quotes was not made by us but by Mr. E. C. Bellows, the Californian Commissioner of Corporations. We feel sure that Mr. Harrop's criticism will be seen by Mr. Bellows in due course. As to the constitutionality of the law, we note that an opinion was handed down by the State Supreme Court on August 25, upholding the Corporate Securities Act, through which the Commissioner derives his authority.—EDITOR.]

Russian Placer Mining

The Editor:

Sir—In the issues of your paper for March 19 and 26, and April 2 of the present year, Mr. Leon Perret attacks well-established methods of winning alluvial gold. While he quite pointedly refers to the lamentable failures of foreign engineers (myself included) in the domain formerly comprised in the Russian empire, his strictures appear to include a general criticism of gravel-mining methods in all countries outside Russia.

The laudation of Russian mining methods by Mr. Perret covers a lateral range of territory hardly to be equalled in any other country, from 60° to 140° east longitude, and a scope of operations ranging from prospecting to gold-dredging and drift-mining. Incidentally he makes arrow-like thrusts at his foreign contemporaries, who are, it is to be presumed, expected to answer his sallies in detail or otherwise to take defeat by default.

Perhaps the best comment one can make regarding the former operations of the Lenskoe Gold Mining Co. in the Vitim district of Siberia is to quote (substituting figures in U. S. currency) the costs of drifting operations from the ninth annual report of the Lena Goldfields, Ltd.,

which formerly held a large block of shares in the Russian concern. In this table the cost of drift-mining in 1913-14 is compared with the same in the two following years, when the modifications of practice introduced by the "American engineers" had begun to affect the results.

Dealing with	1913-14	1914-15	1915-16
	787,150 cu. yd. Per cu. yd.	913,795 cu. yd. Per cu. yd.	753,240 cu. yd. Per cu. yd.
Mining	\$2.70	\$1.98	\$1.52
Tramming	0.43	0.26	0.16
Washing	0.30	0.24	0.26
Development	3.26	0.82	0.33
Construction	0.10
Mine administration	1.06	0.70	0.94
Prospecting	0.06	0.27	0.02
Bulion realization	0.12	0.12	0.02
Total working cost	\$4.93	\$4.39	\$3.35

This shows a saving on the items mentioned of well over \$1,000,000, comparing the first and last seasons quoted on the average quantity of gravel dealt with. The above items relate to ordinary mining operations which came to a certain extent under the control of Messrs. Purington and Smith. They do not include head-office charges, agencies, depreciation, losses on store-keeping and steamboat operation, war levies, excess-profit taxes, and general amortization.

For the four years during which I was concerned with the technical operations of the Lenskoie company, the cost of mining, tramming, and washing showed the following changes:

	1912-13	1913-14	1914-15	1915-16
Mining	\$2.42	\$2.70	\$1.98	\$1.52
Tramming	0.50	0.43	0.27	0.16
Washing	0.39	0.30	0.24	0.26
Total	\$3.31	\$3.43	\$2.49	\$1.94

Contributing factors to the diminution of cost were the reduction of man and horse labor, especially in tramming gravel; the successful application of winter-washing methods, by which all gravel was washed as mined throughout the year; a more systematic and economical laying out of the drifting-blocks in development; and a considerable amount of recovery of the heavy timbers employed, so that they could be used again.

Many of the desirable features above outlined were suggested by Mr. Perret in 1913, and discussed between him and me. The departure of Mr. Perret from the property in 1914 deprived those left in charge of the benefit of his supervision, and the suggestions made by him as well as the plans he initiated naturally underwent considerable modification later.

In regard to the long sluices which were erected in 1914 and following years, and which Mr. Perret so severely criticizes, it is worth while quoting the following unsolicited testimonial from the annual report (in Russian) of the Lenskoie Gold Mining Co., submitted to the annual meeting of shareholders at Petrograd on September 30, 1915:

"The improvement of washing appliances, that is, the gradual transition from trommel machines and *kulibinas* to long American sluices of Alaskan type has given an important reduction in the loss of gold in washing processes, and at the same time has contributed to the lowering of the washing cost. Thus (converting Russian into

U. S. figures) in 1912-13, 830,000 cubic yards cost 56 cents per cubic yard to wash, say \$465,000, while in 1913-14, 873,000 cubic yards cost only 35 cents per cubic yard, or \$306,000, a saving of over 36%."

The Lenskoie accountant in the above figures has added certain items to washing cost which I have always considered as belonging to tramming, but this fact does not affect the value of the comparison.

The result of winter washing during four years is summarized below:

	1913-14	1914-15	1915-16	1916-17
Year's output of gravel washed, cu. yd.	873,635	974,234	788,942	569,679
Winter washed, cu. yd. ... Experimental	242,420	287,280	299,570	
Percentage washed in winter	25	36½	52½

For the winter of 1916-17 nearly 80% of the gravel actually mined was washed at once; and, as shown above, taking the entire season's output, more gravel was washed in the winter than in the open season.

Trommel washing-plants such as Mr. Perret enlogizes are used at drift mines in Australia, California, and Alaska, where conditions warrant the use of same. Such a plant is in fact depicted and described by me in Bulletin No. 263 of the U. S. Geological Survey, pages 78-81, as having been inspected by me at the mouth of Bear creek in 1904. It was said to have a capacity of 800 cu. yd. in 24 hours, was not particularly economical, and was soon afterward discarded.

The main reason for superseding trommel machines at Lenskoie by sluices was one that Mr. Perret appears to have entirely overlooked, namely, the desire to take advantage wherever possible of the transporting power of water, of which there was abundant supply, in the distribution of the tailing. A second objection to the trommel was its inadaptability to winter washing, at temperatures of from 40° to 60°F. below zero.

The marked increase in yardage treated from drifting operations, as well as in the gold recovered, comparing the seasons of 1913-14 and 1914-15, is of interest, and, to say the least, it is a curious coincidence that these increases should have occurred simultaneously with the development of the methods introduced by the foreign engineers.

	1913-14	1914-15
Yardage treated	873,635	914,029 (drifting only)
Total drifting output	\$6,150,000	\$8,600,000
Recovery per cu. yd.	\$7.92	\$9.40

One thing should be remarked in this connection: it is certain that much of the gold stealing, which when I first went to the property was estimated to amount to over \$1,500,000 annually, was done away with by the elimination of the winter dumps, and of the old methods by which the miners and surface-men were enabled to handle the rich gravel many times in its progress from the face to the tailing-piles.

As regards the Russian miner, for whom Mr. Perret is so enthusiastic an apologist, the following comparison shows as nearly as possible the work performed in the Lenskoie district in 1915. The Californian example cited is the old Red Point drift mine, the data being supplied to me by Ross B. Hoffman who collected them in 1892.

The two Lenskoie examples, are first, that of the Lenskoie company's work, in which the laborers appear to have had a low efficiency partly owing to that exaggerated paternalism of the Russian mining law, so fully described by Mr. Perret. The second example is taken from data collected by me in my inspection of a tributers' drift mine on the Nigri river, where the Russian laborer had, so to speak, to look out for himself. In this second case the duty of the man at the face was equivalent to that of the American drift miner in California.

Duty in cu yd per shift:	Lenskoie	Tributers	Red Point
Per man employed at the face.....	1.4	2.3	2.3
Per man employed in all departments.....	0.45	0.85	1.5

I have had little experience with Russian laborers, but in general find them better suited to agricultural than to mining pursuits. At the mines of the Orsk Goldfields on the Pacific coast of Siberia, Chinese and Koreans were used almost exclusively and were very satisfactory.

It would seem that cost data and figures of output such as those above given, and mainly quoted from published reports, are the best answer to the numerous criticisms of Mr. Perret. To describe again the technical methods installed at Lenskoie or other places in Siberia would be but repetition, as I have already been at some pains to describe these together with the results attained, and reference may be made to the technical press in which the articles were printed.

As regards further points in Mr. Perret's articles, it seems that he has been quite effectively answered by your other correspondents, and it would not appear that any useful purpose can be served by further prolonging an academic discussion which relates to past and forgotten incidents.

C. W. PURINGTON.

London, June 27.

Indexing Current Technical Literature

The Editor:

Sir—From your thorough analysis of this subject in your issue of August 6 it would appear that there is no regular or complete publication which is devoted entirely to the indexing of current literature on mining, metallurgy, and allied topics, and I believe that your diagnosis is correct. The weakness of 'The Engineering Index' and 'Chemical Abstracts', in respect of their value to the mining profession, is that they cover every branch of engineering. Moreover, the present arrangement of this index, started in 1919, scatters mining topics throughout a volume of nearly 600 pages, and even then it is not complete. Formerly this matter was concentrated under 'Mining and Metallurgy'. While 'Chemical Abstracts' is excellently done, and is issued twice a month, it does not record all of the published matter relating to mining. Its 800-page annual, which is simply an author, subject, and formula index, is somewhat awkward, as each item has a number, and one must have the whole year's abstracts (24 of them) beside one to find any particular reference, although the annual index

does give a line or two on the matter.* Having disposed of these three excellent yet unsatisfactory indexes, what has the mining man got for ready reference devoted exclusively to his profession? Apparently very little. The indexes of recent papers prepared by the I. M. & M. and A. I. M. & M. E. are also deficient—one in scope, the other in form. Without doubt, the best international bibliography—for such any new index must be—of mining and metallurgy was the 'Mining World' index, published twice a year from 1912 to 1916, inclusive. When it was absorbed by the 'Engineering and Mining Journal' its usefulness came to an end. Abstracts were made from 400 publications, 190 of which were foreign. (The 'Engineering Index' covers 325 domestic and 325 foreign papers; 'Industrial Arts', 150 in all; and the A. I. M. & M. E. a total of 1300 journals, this last figure being your own.) The 'Mining World' system was that of alphabetical listing, with a brief synopsis of the article, under 19 different heads and 'Miscellaneous', the latter coming at the end of each main head. Then there was an author's index and a subject index. The U. S. Geological Survey list of publications, of 187 pages, has a similar arrangement. The whole was extremely simple, complete, and reliable, and cost \$1.50 per half-yearly volume.

Several questions now arise: how many mining and metallurgical engineers want such a reference? What would be the cost of a regular monthly and half-yearly index? Where is a library in which this work could be done? Who would do the abstracting? How would the abstractors be recompensed and what would be the subscription?

It would seem that private enterprise could not make such a bibliography thorough and yet profitable, therefore some technical journal or society must do it, and as the two leading mining journals are not inclined in that direction, it looks as if the national mining-engineering society—the A. I. M. & M. E.—was the logical one to undertake the work, already having the foundation laid for such a publication. It has access to the great technical library in the Engineering Societies building in New York, and is in a position to ascertain the demand, cost, and price. In addition to a half-yearly index, monthly supplementary lists could be distributed, as is done by the Geological Survey. Such matter could be mimeographed, and mailed promptly. A 6 by 9-inch page is most suitable for the bound volume. This matter of prompt publication is of great importance, because, if an engineer learns of an article, and yet cannot get a copy of the particular technical journal, he now can write to that publication, or the United Engineering Societies library, and procure a photostat of the complete article at a cost of only 25 cents per page.

As you say, abstracting is no mechanical operation: it

*The Industrial Arts Index, published monthly, half-yearly, and annually, in New York, is a cumulative index to engineering, trade, and business periodicals, but is also unsuitable, in that it is too general, and mining is scattered through over 600 pages.

requires engineering and editorial ability and great patience. I have done a good deal of this work myself, and know what is required, and believe that a resuscitation of the 'Mining World' index would be a good idea.

This brings me to an allied topic, that of special bibliographies. The value of any bibliography lies not only in articles having titles that indicate the topic, but also in those on any subject to which the particular reference is made. For instance, suppose that a bibliography on 'Explosives' is being prepared, and the bibliographer sees an article entitled 'Quarrying Marble in California'; many might pass that by, but a trained man would scan the text for any mention of blasting, which would then be noted. Therein lies the skill of the abstractor. During the preparation of a bibliography on sampling, not yet published (some of the references go back 30 years, but most of them cover the last 10 years to mid-1921, and it is a fairly complete record), it was very noticeable that in otherwise well-written articles, unless they were directly on sampling, this important matter was either entirely omitted or received only a line or two. In describing a mine, mill, or smelter, the method of sampling appear to be taken as a matter of fact, therefore little space is devoted to them. I should think that every engineer who describes a mine or works should say how the sampling was done. For instance, in your issue of July 23, Mr. J. N. Nevius discusses 'Resuscitation of the Octave Gold Mine', but not a word is said on the method of sampling, which must have been unusual. Again, in the issue of July 30, your Mr. A. B. Parsons describes the Engels copper mine, but he omitted to state how the mine is sampled; although in the August 8 number he did cover sampling in the mill and show in the flow-sheets where it was done.

I have digressed from indexing to sampling, but such is the trend of one's thoughts when concentrated on a particular subject.

M. W. VON BERNEWITZ.

Washington, D. C., August 11.

Stocks and Prices

The Editor:

Sir—I was much interested in your editorial comment of July 9 on R. H. Tingley's article in the 'Annalist' on the present worth of stocks and bonds, but your question as to "whether stocks will appreciate in price in proportion to a further fall in commodity prices, or is connection between the two so unstable that a rise or fall in the price of both, at one and the same time is possible" seems to me somewhat confusing.

Stocks, with possibly a few exceptions, have not appreciated in price with the fall in commodity prices, or are they likely to do so on a further fall, until the time comes when thoughtful speculators consider that the reduced price will stimulate buying of the product at a profit to the producer.

Stable commodity prices, when they have existed for a sufficient length of time to allow the industry to be thoroughly adjusted to the new conditions, are more likely to

induce higher stock prices, as during this period stocks have passed from weak to strong hands, and taken out of the market; thus creating a scarcity of stocks when the business revival comes.

The rise and fall of stocks, bonds, and commodity prices are phases of the business cycle, which have been indicated graphically in 'Business Barometers' by Roger W. Babson as follows:

DOUGLAS WATERMAN.

Havana, Cuba, July 25.

Indexing Current Technical Literature

The Editor:

Sir—In your editorial of August 6, entitled 'Indexing Current Technical Literature', you say much that is pertinent.

It is pleasant to read your remarks in praise of the excellent work of the American Chemical Society. Many of your readers are doubtless, like myself, grateful for the glimpse you give of the organized team-work that lies behind the Society's achievements. There is, however, one notable bibliography in the mining field that you have not mentioned: I refer to the series of substantially-bound annual bulletins of the U. S. Bureau of Mines entitled 'Bibliography of Petroleum and Allied Substances'.

For your information and comment I enclose a copy of one of these volumes and also an example of the abstracts by which they are at all times kept up to date by their editor, Miss E. H. Burroughs.

ALEXANDER ANDERSON.

Fullerton, California, August 16.

Revision of Mining Law

The Editor:

Sir—I have done quite a lot of prospecting in the desert where government stakes are scarcer than even water, and water may cost in time and labor from 50c. to \$1 per gallon.

If the sponsors of the proposed new law will mount a mule at Goldfield, Nevada, ride to Las Vegas, Utah, then to Daggett, then to Darwin and Keeler, in Inyo county, California, a region rich in mineral prospects, I doubt if they would find one survey stake to tie to.

The proposed law would drive the prospector out of this and all districts like it.

I see no very serious faults with the present law.

FREDERICK SPEAR.

Lone Pine, California, August 30.

Nevada Consolidated Copper Company—V

The Smelter

By Arthur B. Parsons

The smelting of copper ore and concentrate is more thoroughly standardized than many metallurgical operations. Most modern copper-smelting plants are alike; they consist of mechanical multiple-hearth roasters, reverberatory matting-furnaces, and converters, together with the appropriate buildings to house them; and such essential adjuncts as power-plants, transportation systems, flues, and stacks. If the plant is old enough, there

features in describing the smelter of the Nevada Consolidated company at McGill, which, I may say incidentally, conforms to fashion even to the extent of preserving its unused blast-furnace department.

First, however, for the benefit of the 'semi-technical' reader or the young engineer, whose facts and ideas may need sorting and indexing, a few paragraphs will be devoted to a concise description of the three processes in-

PIERCE-SMITH CONVERTERS AT THE STEPTOE SMELTER AT MCGILL, NEVADA

is likely to be a blast-furnace department; the probability is that it has been idle for some years and, moreover, that the furnaces will never run again, although for some strange reason many metallurgists are loath to see these old friends torn down. In spite of this similarity in the important features of copper-smelting plants, and the uniformity of practice in accord with generally accepted principles, there are details of construction and of operating methods, used in individual plants, that are of interest. I shall endeavor to point out a few of these

involved in the smelting of sulphide copper ores or concentrates.

The purpose of roasting is to 'burn-off' sulphur by heating the pulverized ore in the presence of an excess of air. Besides converting part of the copper sulphide to oxide, the iron is oxidized, and volatile impurities such as arsenic and antimony are removed. The temperature varies from 450 to 650°C. and no fusion or even sintering takes place. Roasting was formerly done in a long coal-fired brick furnace with a single hearth, on

which the ore was stirred and pushed to the discharge end by hand-rabbles. The modern type of roaster consists of a series of superimposed circular hearths, onto the uppermost of which the ore is fed; either the hearths or the rabbles revolve, thereby stirring the charge mechanically. The ore passes successively over the lower hearths. The advantages of such a roaster are economy of space, fuel, and labor, and uniform roasting. The product is called calcine.

In the reverberatory furnace the calcine, mixed with the requisite amount of flux, generally crushed limestone, or an ore high in lime, is fused; the sulphur remaining in the calcine acts as a reducing agent and combines to form a copper-iron matte containing 35 to 40% copper; while the silica, lime, and iron, with some alumina, form a silicious slag that goes to waste. The reverberatory is a shallow brick furnace approximately 130 by 20 ft. in plan with a concave hearth and an arched roof of silica brick that reflects or 'reverberates' the heat onto the charge. It is fired from one end with coal or fuel-oil; the height of the smelting-chamber is diminished at the opposite or stack end.

Molten matte is tapped from the reverberatory and taken to the converters. The treatment in the converter consists of two parts: first, the shell is filled to the tuyere-level with matte; silicious ore is added as flux to combine with the iron in the matte, thus forming a slag which is tapped-off to leave 'white' metal or copper sulphide; further additions are made until the shell contains a full charge of white metal. The copper is then 'blown'; that is, air is forced through the bath, decomposing it at 1150°C. into practically pure copper and sulphur dioxide gas, which escapes. The modern converter is a huge cylindrical steel shell, lined with neutral refractory brick, and mounted on a horizontal axis on which it can be revolved. On the top is the throat through which matte and ore are charged; there is a row of tuyeres along the back, and tap-holes for the removal of slag and blister copper are provided in front. This is known as a 'basic' converter in contrast to the old 'acid' converter, in which the lining of silicious material supplied the flux for the iron in the matte, and was gradually eaten away.

The general arrangement of the plant at McGill is peculiar. The group of smelter buildings is situated about three-quarters of a mile north of the concentrator, which supplies practically all of the material for smelting. Moreover, the main smelter buildings themselves are scattered over the hillside with several hundred yards intervening, thereby requiring excessive haulage, a feature that is particularly objectionable because hot materials like matte, calcine, and slag are to be transported. Another unusual feature is the erection of three separate stacks, one for each department; the roaster stack is 250 ft. high and 18 ft. inside diameter; the reverberatories are served by a 300-ft. stack, 22 ft. in diameter at the base; and the converter stack is 90 ft. high and 10 ft. in diameter. Mr. Lakenan, general manager for the company, informs me that the erection of a single stack was

debated at the time the plant was erected, and that the decision to build three individual stacks was based on the assumption that probably two years would elapse before the maximum capacity of the plant would be attained. During that period, low stack-temperatures and insufficient draft would have tended to make operations less efficient and less economical. If the company were to build a new smelter in the light of its present knowledge as to the extent of the ore-reserves at Ruth, and as to the performance of the concentrator, the various buildings would doubtless be arranged compactly and a single central stack would be provided.

The problem of haulage is nicely solved by a complete system of standard-gauge tracks connecting the concentrator, the various smelting buildings proper, and the other departments, which include:

- Coal-dust plant
- Power-house
- Warehouse
- Boiler-shop
- Machine-shop
- Foundry
- Blacksmith-shop
- Carpenter-shop
- Tin-shop
- Magnesite-brick plant

For intra-plant service, small steam-locomotives of Porter or American manufacture, with saddle-tanks and an over-all clearance of only 7 ft., are used. These have a weight of 17 tons on the drivers, and are fired with either coal or fuel-oil.

The introduction of flotation, and the consequent necessity for smelting a considerable amount of fine-slime concentrate containing less pyrite, more silica and alumina, and more moisture than that contained in the concentrate from the Wilfley tables and vanners, has been responsible for sundry changes in smelting practice.

The following average analyses illustrate the difference in the concentrate to be treated. (A) represents the concentrate smelted in 1916, and (B) that in 1919.

	Copper %	Silica %	Iron %	Alumina %	Sulphur %	Moisture %
A	8.00	28.4	23.9	0.8	27.8	10.28
B	8.40	30.7	19.8	9.9	23.9	17.2

The concentrate (B) is a mixture of table concentrate, having a composition similar to that of (A), and flotation concentrate in which, obviously, the sulphur and iron must have been still lower and the kaolin constituents still higher than shown in the analysis of (B).

Although an increased proportion of flotation concentrate was produced in 1920, the character of the mixture changed somewhat, as may be seen from the analysis given at the conclusion of the discussion of 'roasting'. The physical condition of the flotation concentrate is also important. Not only are the particles exceptionally fine, 85% passing through 100-mesh and 60% through 200-mesh, but after dewatering in vacuum filters the concentrate acquires the consistence—characteristic of all filter-cake of fine flotation products—which can best be compared with that of tooth-paste squeezed out of a tube

in cold weather. The problem of successfully treating a mixture consisting in part of a filter-cake such as just described presented itself in 1917, at which time the McDougall roasters were altered for the purpose of meeting the new requirements.

ROASTING. The end in view in making the changes was to effect a complete disintegration of the caked material and a thorough mixing with the granular concentrate before it reaches the temperature of actual roasting. Intimate admixture would make the sulphur in the more pyritic portion available as a fuel for assisting the roast of that portion of the material less rich in sulphur. R. E. H. Pomeroy, then smelter superintendent, and J. C. Kinnear, who recently succeeded Pomeroy, and who was at that time his assistant, originated the scheme for altering the furnaces, and they later collaborated in preparing a paper describing the results of their work. This paper was read before the Nevada Section of the A. I. M. & M. E.; many of the details of the following description of the modifications made in the furnace are taken in condensed form from this paper, as there have been no substantial changes in the practice since that time except the substitution of pulverized-coal burners to take the place of the fire-boxes for burning ordinary coal, that were built in 1917. It was found that the comparatively low sulphur content, and the large proportion of moisture that must be evaporated, necessitated some fuel other than the contained sulphur. The most efficient place to apply the extraneous heat was found to be the fifth hearth, that is, the fifth from the top, at which point the flame from the present pulverized-coal burners impinges. Most of the roasting takes place on the fifth or six hearth, depending upon the character of the feed.

The McDougall furnaces originally installed had six hearths, 18 ft. in diameter, and were water-cooled. The alterations were as follows:

(1) Air-cooling was substituted for water-cooling. The air, under a pressure of 2.9 in. of water, passes up through the centre column and out through the arms. It is discharged through holes in the bottom of the arms between the rabble-heads. This air jet, impinging directly upon the turning bed of calcine, serves the double purpose of cooling the arms and centre column and of directing the heated air upon the hot calcine. The velocity is not sufficiently high to cause excessive dusting. This air is supplied by two fans made by the National Blower Co.; the fan wheels are 84 in. diam., the vanes are 42 in. wide; they are driven at a speed of 360 r.p.m., by 100-hp. motors. The delivery, as measured by Pitot-tube readings, is 113,000 cu. ft. of free air per minute. This approximates 4700 cu. ft. of air per furnace per minute. Distributing headers of ample cross-section have been provided with blast-gates at each fan and at each furnace. Each centre column is provided with a wind-box or bustle-pipe equipped with a stuffing-box to prevent leakage of air.

(2) Owing to the higher moisture and lower sulphur content of the mixed feed since the development of the

flotation process it has been found necessary to increase the period of roasting and drying. The furnace shell was extended upward 4 ft. 7 in. and the number of hearths increased from six to eight by the addition of one working chamber and the utilization of the top or roof of this new chamber as a drying-hearth open to the atmosphere. The feed is dropped from the feed-hopper upon the periphery of the drying-hearth.

(3) The addition of this eighth hearth resulted in the convenience of allowing the effluent gases to pass to the flue through a gas outlet situated at the centre of the furnace around the top of the centre column. This feature permits a symmetrical distribution of the heat passing under the drying-hearth, and produces an efficient drying-surface for the wet feed.

(4) It was determined by experiment that the most suitable mechanism for handling large proportions of flotation concentrate on the drying-hearth was a set of revolving disc-harrows like those commonly used in farming. The action of these discs is to cut up the masses of caked concentrate as fed upon the hearth, turning, rolling, and coating them with the coarser sulphide particles, thus preventing further agglomeration. The idea was suggested by the method of the baker dusting his sticky dough with dry flour to prevent its adhesion to hands and utensils. A further advantage of this disc arrangement, over the scraper-plow commonly used, is the fact that the material is completely turned down to, and in contact with, the drying surface at each pass, thereby exposing new surfaces to the drying-hearth and to the atmosphere. In contrast with this, the wear on the bottom of the usual scraper-plow allows an ever increasing protecting layer of dried material to accumulate between the drying surface and the fresh concentrates. The idea of 'flouring' the chopped cake gives a key to one important reason for the decision to precede flotation with concentration on roughing-tables as outlined in the previous article describing the concentrating plant. One unit has been remodeled to provide for the fine grinding of the entire mill-feed, followed by flotation and tabling of the flotation tail; in the most recent^{est} unit, however, a table concentrate is made preliminary to fine grinding. A considerable quantity of granular concentrate is thereby obtained, and it is this material that the smelter metallurgists particularly desire. This brings out an interesting point: the advantage to the enterprise of having unified control over all operations. Each branch of the work is conducted with due consideration for the requirements of the other departments; the end in view being to obtain the maximum net profit.

(5) Much trouble was experienced with the old line-shaft drive with a friction-clutch and belt at each furnace. This drive has been entirely replaced by individual 10-hp. motors, direct-connected to the driving-gear through enclosed spur-gear speed-reducers running in oil. The gearing has been let down about three feet to remove the motor and gearing further from the hot under-surface of the lower hearth. The speed of the centre column was increased and the column now makes

one complete revolution in 34 seconds as compared with 38 to 55 sec. formerly.

(6) In keeping with modern ideas of furnace construction, the floor-arches of common brick have been replaced by fire-brick tile of large dimensions and specially shaped to form the required circular arch. The area of the central drop-hole has been maintained at 23.2 sq. ft., which has proved satisfactory.

(7) Provision has been made to feed the lime-rock required as flux in the reverberatories into the roaster, where it is dried, heated, and intimately mixed with the calcine. The mechanical lime-rock feeders have been so situated as to feed onto the seventh hearth, which is the one next the bottom. The hoppers above the feeders have been made triangular in shape in order to give the maximum storage capacity, each hopper serving two adjacent furnaces. The lime-rock is a locally quarried stone of good quality crushed to $\frac{3}{4}$ -in. size; the proportion of limestone to concentrate is approximately 8.4%.

One recent change that should be mentioned is the substitution of an improved feeder for the balanced-plunger feeder designed at the time the changes just outlined were made. The plunger feeders did not work efficiently even when 60% of the concentrate was from the gravity units in the mill. The new device is of a pan-conveyor type consisting of a series of drags with sprockets and chains. The thickness of the exuding 'ribbon' of concentrate is regulated by a rack-and-pinion gate built above the conveyor and in the front of the small storage-bin.

There are 24 roasting-furnaces. The mill-concentrates are hauled to them in 10-ton hopper-bottom cars, and the calcine is hauled to the reverberatory storage-bins in 8-ton cars. The following data are averages covering the operations for the last 6 months of 1920.

Concentrate roasted per furnace-day, tons.....	55.9
Lime-rock per furnace-day, tons.....	4.7
Total fed per furnace-day, tons.....	60.6
Sulphur eliminated per furnace-day, tons.....	11.7
Water eliminated per furnace-day, tons.....	7.9
Calcine produced per furnace-day, tons.....	50.78
Sulphur eliminated, %	79.5
Pulverized coal used per furnace-day, tons.....	0.28
Pulverized coal used per ton roasted, lb.....	10.2
Pulverized coal used per ton of water evaporated, lb.....	72.1

Analysis of Roaster Feed

Copper	Silica	Iron	Alumina	Sulphur	Moisture
%	%	%	%	%	%
8.04	29.0	23.3	7.5	26.3	12.3

REVERBERATORY SMELTING. The reverberatory plant originally comprised five matting-furnaces built according to the Anaconda design, four of them being 121 ft. long by 19 ft. 6 in. wide, inside dimensions; the fifth, 130 ft. long by 19 ft. 6 in. wide, with a capacity of about 625 tons total charge per day. One of these has been replaced by a new furnace which will be mentioned later. Pulverized coal, used as a fuel, is furnished to the plant by the Holbeck system, a description of which is embodied in the portion of this article covering the coal-pulverizing plant. Pulverized coal has been found to be entirely satisfactory in every respect and has at all times been as dependable as fuel-oil.

Until the middle of 1920 the reverberatories were of the old centre-drop type, fettled or clayed through side

doors arranged along the entire length of the furnace. The greatest corrosion of the sides took place along the 50 ft. nearest the charging and firing end; particularly careful fettling at this point was necessary. One-half of the furnace was fettled every 8 hours; the remainder, once every 24 hours. This work required a force of 35 to 40 men daily. Side charging had never been attempted at this plant for several reasons. The width of the furnaces, as originally built, and the position of the charge-floor, running transversely across the furnaces at the firing-end, and extending only 16 ft. toward the opposite end, necessitated either the use of screw- or drag-conveyors, or a prohibitive rearrangement of the tracks. To overcome this difficulty, long charge-bins were hung from the charge-floor, extending over the furnace for 50 ft. from the firing-end. Advantage is taken of the fact that calcine when hot will flow like water to the extreme end of the long charge-bins. From these bins the calcine is fed through a series of pipes inserted through the roof and along both sides of the furnace over the whole of the 50-ft. section. The result is the filling of both lower corners of the furnace (looked at in cross-section) with calcine, thereby completely protecting the sides, and forming a trough-shaped space for the molten charge. Whether the operation is called fettling or charging is immaterial; both are effectually accomplished.

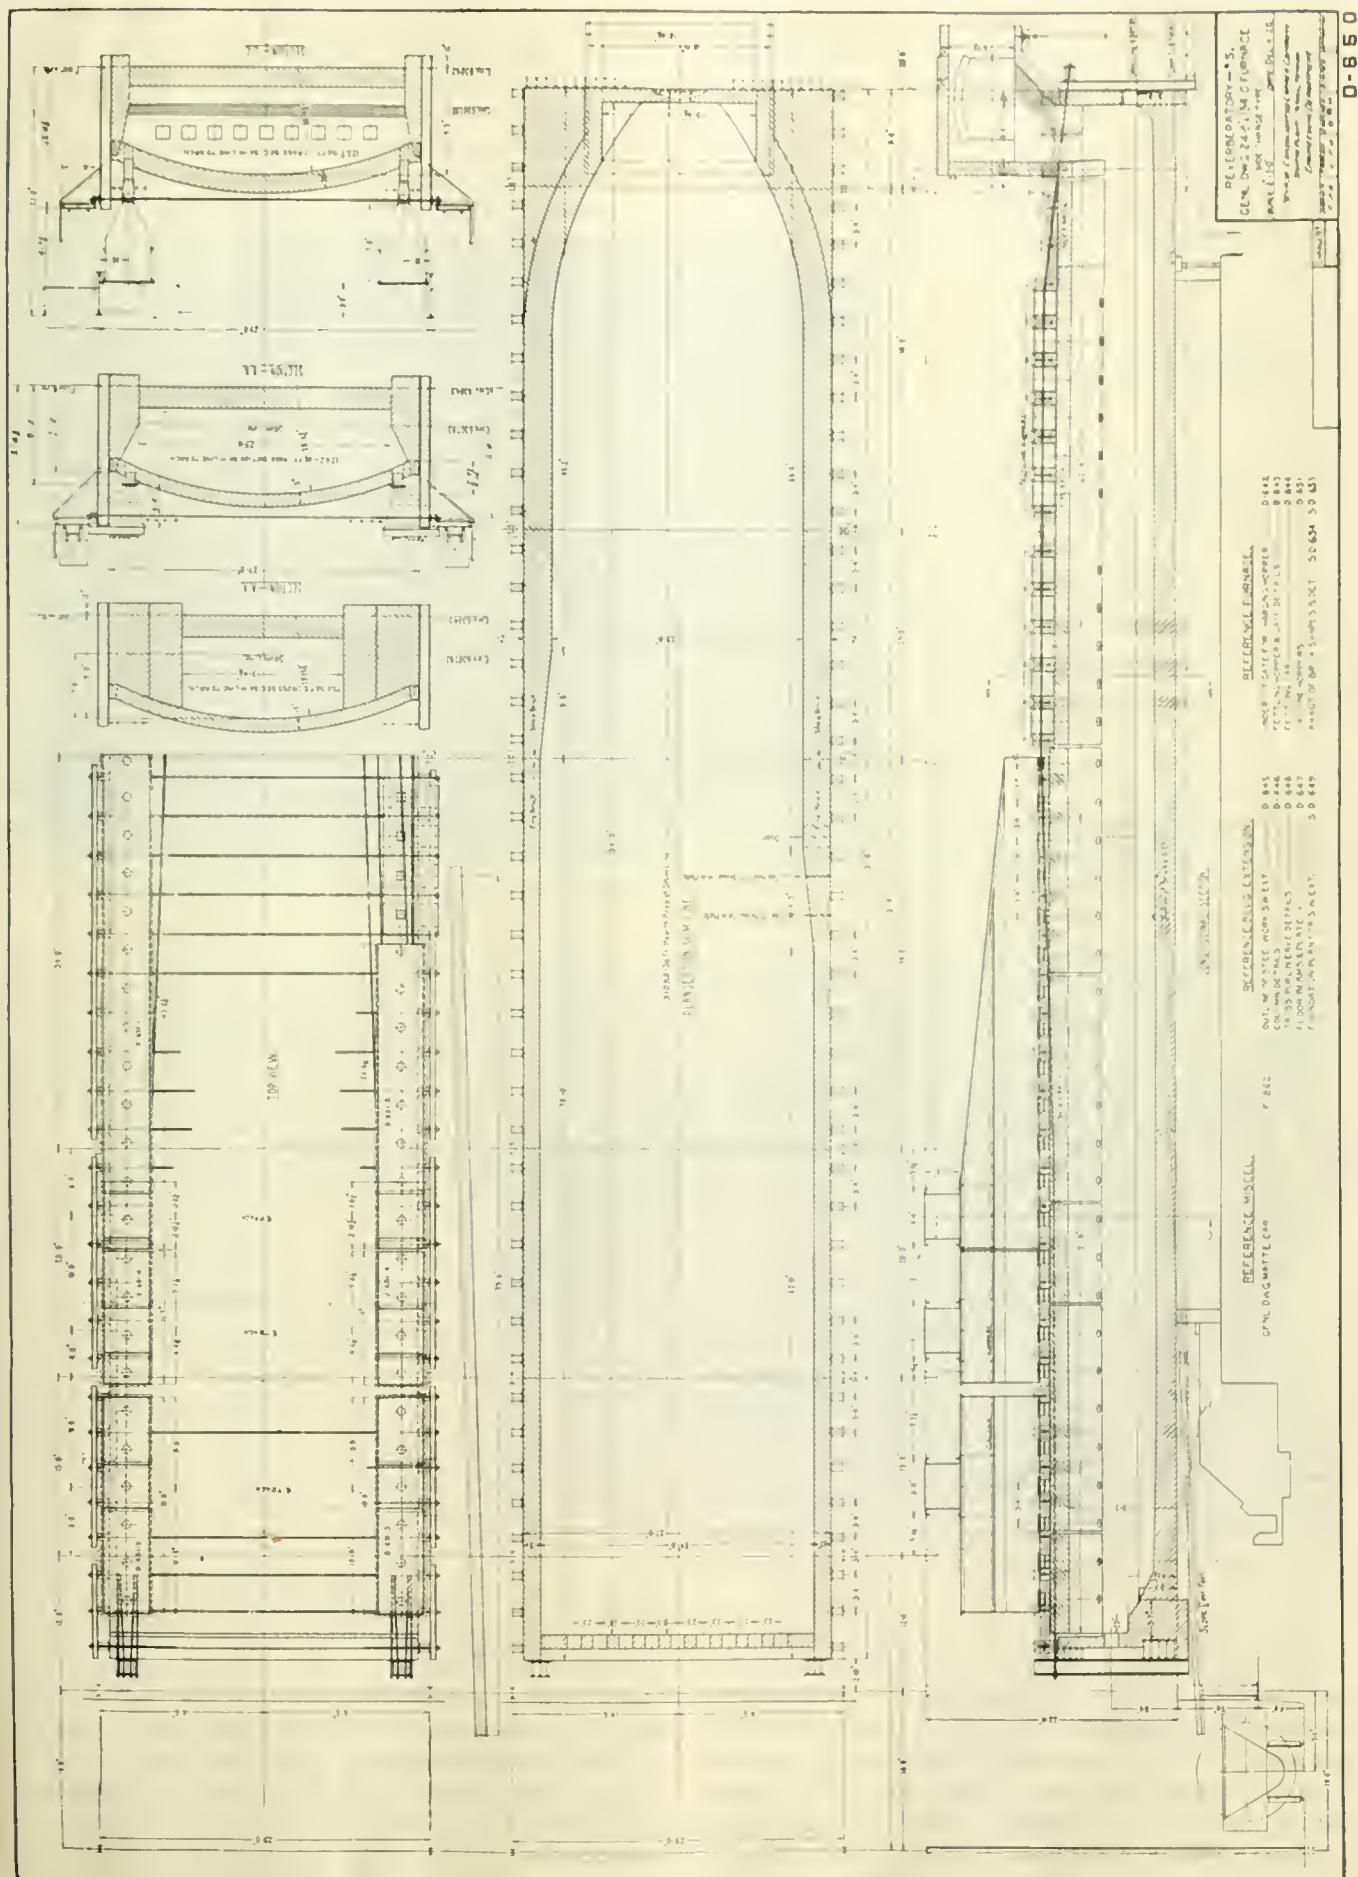

For some distance beyond the 50-ft. point, concentrate and miscellaneous products are introduced as fettling in the usual way, but this is a comparatively light task. The force of men engaged in this work has been reduced from 35 to 10. Two furnaces have been operated along the above lines and have proved in every way satisfactory. The new furnace recently completed is 134 ft. long and 24 ft. wide, with a hearth-area at the skim-line of about 3000 sq. ft. This furnace is provided with mechanical charging and fettling equipment the details being shown in the accompanying drawing. In its design, for which Mr. Kinnear is responsible, are incorporated the latest and best ideas of reverberatory construction.

Two waste-heat boilers are placed parallel with each other in the exit flues, the steam thereby generated being used to supplement the boilers in the main power-plant. Two reverberatory slag analyses are shown below. 'A' represents slag made in 1915, whereas 'B' is typical of the practice in 1920. The change in character of the concentrate smelted is thereby reflected.

	Copper	Silica	Iron	Lime	Alumina
	%	%	%	%	%
A	0.345	42.6	36.3	10.3	6.5
B	0.40	40.0	29.7	5.5	11.1

The slag is granulated by being run directly into a stream of discarded mill-water by which it is carried to the dump.

The flue-dust from the roasters is re-smelted directly in the reverberatories, except for the portion that collects in the segment of the flues nearest the stack; this contains a large proportion of soluble copper and is accordingly leached with water in a concrete launder. The liquor is decanted in settling-tanks, and passed over iron

for the precipitation of the copper. The precipitate is used for fettling; the residue is temporarily discarded.

The following statistics summarize the operations for the last six months of 1920:

Average grade of matte, copper, %.....	39.8
Total charge	Solid charge
Charge per 100 sq. ft. of hearth-area, tons.....	25.6 23.5
Gross coal, on the charge, %	17.6 19.1
Net coal, on the charge, %	13.2 11.3

The average proportions of materials in the charge were:

Material	%
Calxine and flue-dust	77.3
Cold secondaries from converters	5.5
Hot converter-slag	8.3
Lime-rock	6.9
Fettling	2.0

The following are typical analyses:

	Moisture	Copper	Silica	Iron	Lime	Alumina	Sulphur	Magnesite
	%	%	%	%	%	%	%	%
Calxine	25.8	8.85	31.9	25.6	..	8.2	5.9	...
Converter secondaries	28.37	16.8	28.5	1.1	5.8	9.5	...
Converter slag	1.68	25.7	48.3	0.25	5.0	0.93	0.59
Lime-rock	1.5	0.3	49.3	0.4	..	3.3
Fettling	25.8	3.35	45.8	5.4	..	20.9	5.3	...

The fettling material consists principally of low-grade flotation concentrate.

CONVERTING PRACTICE. Matte from the reverberatories under usual conditions contains 38 to 45% copper; it is tapped into a transfer-car improvised from an old converter-shell mounted on a standard railway-truck with a trunnion at each end to permit dumping. The pot itself is lined with fire-brick and has a roof of silica brick nine inches thick. The inside dimensions are 7 ft. diam. and 10 ft. long. At each of the reverberatory furnaces a pulverized-coal firing-station is provided, and as well as at each converter. It is accordingly possible to apply extraneous heat to the matte and to the car itself at all times except during the intervals of actual travel between the reverberatories and converters. The cars have a capacity of 35 tons of matte when newly lined, at the end of a period of six months, when they are re-lined, they hold from 15 to 20 tons.

These pots allow rapid charging of the converters, both for the initial bath, and for the intermediate chargings later in the cycle. Converter requirements for matte are always anticipated, the matte-pot being filled and held ready under fire on the converter charge-floor. Actual time-records show that a converter can be given its initial bath in about one hour. This compares favorably with the time for the same operation when accomplished by the use of cranes and ladles where converters and reverberatories are under one roof.

As originally built there were four converter-stands to accommodate shells 126 in. long by 96 in. diam. lined with the same silicious carbonate copper ore that is now used as flux. These were thought to be large at that time. The development of the 'basic' converter with a 'permanent' lining, however, resulted in the installation of the present equipment in 1912 and 1913.

The two Pierce-Smith horizontal converters are 36 ft.

long and 10 ft. in diameter with a nominal capacity of 50 to 60 tons of copper. Each converter has 34 cast-iron tuyeres, that are supplied with air at 12-lb. pressure. The lining in the working segment of the converter is made of magnesite brick and is 12 in. thick except at the tuyere-zone where this is increased to 18 inches.

Magnesite brick is made at the smelter in a small plant adjacent to the converter building. Old brick-bats are pulverized and mixed with fresh raw magnesite in an ordinary clay-mill with a revolving bowl and two stationary mullers. The bricks are shaped in a hydraulic press at 240-lb. pressure, steam-dried at 90° F., and fired in a 15-ft. beehive kiln for which coal is the fuel. One great advantage in making the bricks instead of buying them, is the convenience of being able to make special shapes to suit exact requirements. The tendency has been to make bricks of large size in order to avoid mortar joints, particularly at the tuyeres, the point of first weakness. When a converter is being lined, the bricks are laid in thick magnesite clay.

The cars of hot matte approach the converter building on a bench above the working-floor, and immediately behind the converters, so that the matte is poured directly into them. Flux is dried in a small rotary drum, and is charged to the converters by means of boats lifted by one of two 50-ton Shaw electric cranes. Silicious carbonate copper ore from the steam-shovel mine at Ruth is the flux used, a typical analysis being as follows:

Copper	Silica	Iron	Alumina	Sulphur
%	%	%	%	%
2.31	55.9	15.2	6.6	0.2

A feature of the converter operations is the method of recording the performance on each charge. By means of this record the metallurgist is able to determine the efficiency of each step in the operation and to detect delays, faulty manipulation, or failure of equipment. The standards given in the last column below are based upon actual records obtained over long periods under varying conditions and with mattes of different copper content; they become part of the report made on each charge.

The following is a copy of one such report:

NEVADA CONSOLIDATED COPPER CO., STEPTOE PLANT
Pierce-Smith Converter No. 2

	Hr. Min.	Minutes per ton blister	Minutes per ton iron slagged	Standard minutes per ton
Initial bath	1—25	1.7	...	1.0
Charge, skim, and flux ..	4—10	5.0	...	6.5
Blow high	8—10	..	10.2	12.8
Blow copper	4—15	5.1	...	5.0
Ladle to receiver	1—0	1.2	...	1.0
Miscellaneous delays	1—30	1.0
Total	20—30
Matte, tons	148	Matte, copper, %.....	37.1	
Tuyeres	31	Tons blister	49.6	
Bars of copper	216	Tons per hour	2.42	Standard
Ratio to standard	100%			

Each converter is equipped with a mechanical recording device by means of which the elements of time and position are automatically indicated on a chart. The dial on which this chart is mounted revolves by clock-work; the position of the converter on its axis is recorded by means of a pencil. It is therefore possible to obtain absolutely reliable data for the first column in the report,

irrespective of possible neglect or deliberate deceit on the part of the operators. It has been found that from a 30% matte 1.9 tons of copper should be blown per hour; from 38% matte, 2.35 tons; from 40% matte, 2.6 tons; and from 50% matte, 3.1 tons. From charge 2951, for instance, 2.42 tons was blown as against 2.41 standard;

The blister, averaging 99.5% copper, is cast in a straight-line conveyor-type machine. Ingots with a maximum weight of 450 lb. are delivered onto an inclined apron-conveyor that carries them through a vat of cooling-water and finally deposits them on the weighing-floor. The molds are cast of copper, these being a great improvement over the former iron molds. They last only a few months, but since they are made cheaply of blister, and when worn are simply thrown back into the converters along with the scrap, they are highly economical.

Secondaries, including shells and skulls from the ladles and converters and spilled material, are loaded into standard steel railway-cars by means of an orange-peel bucket and are returned to the reverberatories for re-smelting.

Below are the results of converting operations during the last six months of 1920.

Matte converted per month, tons.	6271
Copper content, %	39.8
Blister per lapsed hour per converter, tons	2.38
Hot slag produced per ton blister, tons.	1.90
Pot-skulls produced per ton blister, tons.	0.11
Total secondaries produced per ton blister, tons	2.01

COPPER-RECEIVER EQUIPPED WITH POWDERED-COAL BURNERS

thereby making the efficiency of operation 100%. The value of this form of record is apparent in that it supplies a key to any difficulty around the plant. For instance, if the period 'Initial bath' is high, the possibility of some irregularity in tapping matte at the reverberatories or in transportation is suggested.

Slag is returned in molten condition to the reverberatories in 10-ton tilting slag-pots; copper is tapped into 10-ton ladles. The ladles are carried by the cranes and emptied into a tilting copper-receiver, fired by pulverized coal and lined with magnesite brick. The use of this receiver, which has a capacity of 50 tons, is advantageous in that it permits a converter to be emptied promptly, so that a new converter charge may be commenced at once. Mr. Kinnear has found that it is more economical to line the receiver with magnesite brick than with fire-brick as is usually done. The actual life of one magnesite lining has been 17 months and 22 days, and from this lining 42,462 tons of blister has been cast. By actual tests, although the cost of magnesite lining is about three times that of the fire-brick, the cost of lining per ton of blister in the case of the magnesite is about one-half that of the fire-brick.

35-TON CAR USED FOR THE TRANSFER OF MATTE

COAL-PULVERIZING PLANT. Probably the most modern and efficient part of the smelting works is the coal-pulverizing plant, the construction of which was commenced in 1917. It was completed and put in full operation on May 1, 1918, and has since given continuous and satisfactory service. The increasing cost of fuel-oil and the consequent need for a cheaper fuel became evident early in 1917, and pulverized coal seemed to be the logical substitute. A number of plants for pulverizing coal and dis-

tributing the dust were in operation at that time but in the design of that at McGill departures were made from general practice, with a view to greater safety, cleanliness and efficiency. The plant has been described in an excellent paper by Mr. Pomeroy,* presented at the New York meeting of the Institute in February 1920. The advantages of the system adopted over previous methods, as pointed out in this paper, are: (1) equal safety; no pulverized coal is stored at the furnaces; (2) greater ease of operation, since the furnace fires are regulated by valves in the branch lines leading to the burners; (3) better centralization of operations; the pulverizing machinery and the feed-control are in a single building, and the operating organization is distinct from the actual smelting departments; (4) greater cleanliness assured by placing the machinery under vacuum; and (5) greater flexibility of distribution whereby the pulverized coal, properly mixed with air, can be piped to any part of the works. Among measures for safety may be mentioned the erection of the building with structural steel, covered with corrugated sheet steel; concrete floors and reinforced-concrete bins, subdivided into fire-proof compartments for storage of coal, with adequate provision for detecting any excessive temperature, so that coal can be withdrawn from any bin in the event the temperature rises beyond the point of safety; sundry suction-pipes connected with suitable exhaust-fans for preventing the accumulation of dust in inaccessible corners; various precautions to prevent over-heating in connection with the operation of the dryers; emergency explosion vents and doors in the pulverized-coal bins, suction-headers, and elsewhere.

Run-of-mine coal from the storage-bins is fed by reciprocating pan-feeders to Pennsylvania single-roll crushers, from which it emerges as slack. It passes over Merrick weightometers and then to Ruggles-Coles type A-14 dryers, the fuel consumption of which is 0.75% on the coal dried. The dried coal is pulverized in eight 36-in. Bonnot mills, from which the dust is collected, by circulating air, to be stored in four 50-ton bins.

From cast-iron hoppers at the bottom of these bins the pulverized coal is drawn by feed-screws and dropped into the air current in the main suction-header leading to the distributing fans. Quoting from Mr. Pomeroy's paper: "These feed-screws are driven through roller chains by direct-current, variable-speed motors, the speed of which is regulated by a sheet-metal cone floating in the air current in the main suction-header, and known as the indicator. This device is connected, by light cable over sheaves, to the regulator mechanism, which, through a rheostat, governs the speed of the feeder-motors in proportion to the amount of air flowing in the suction-header. The proportion of air to coal may be varied within limits, but it has been found best to maintain a ratio of 50 cu. ft. of air to 1 lb. of pulverized coal. An instrument attached to the indicator continuously records the rate at which the air is flowing, and revolution counters record the operation of the feed-screws.

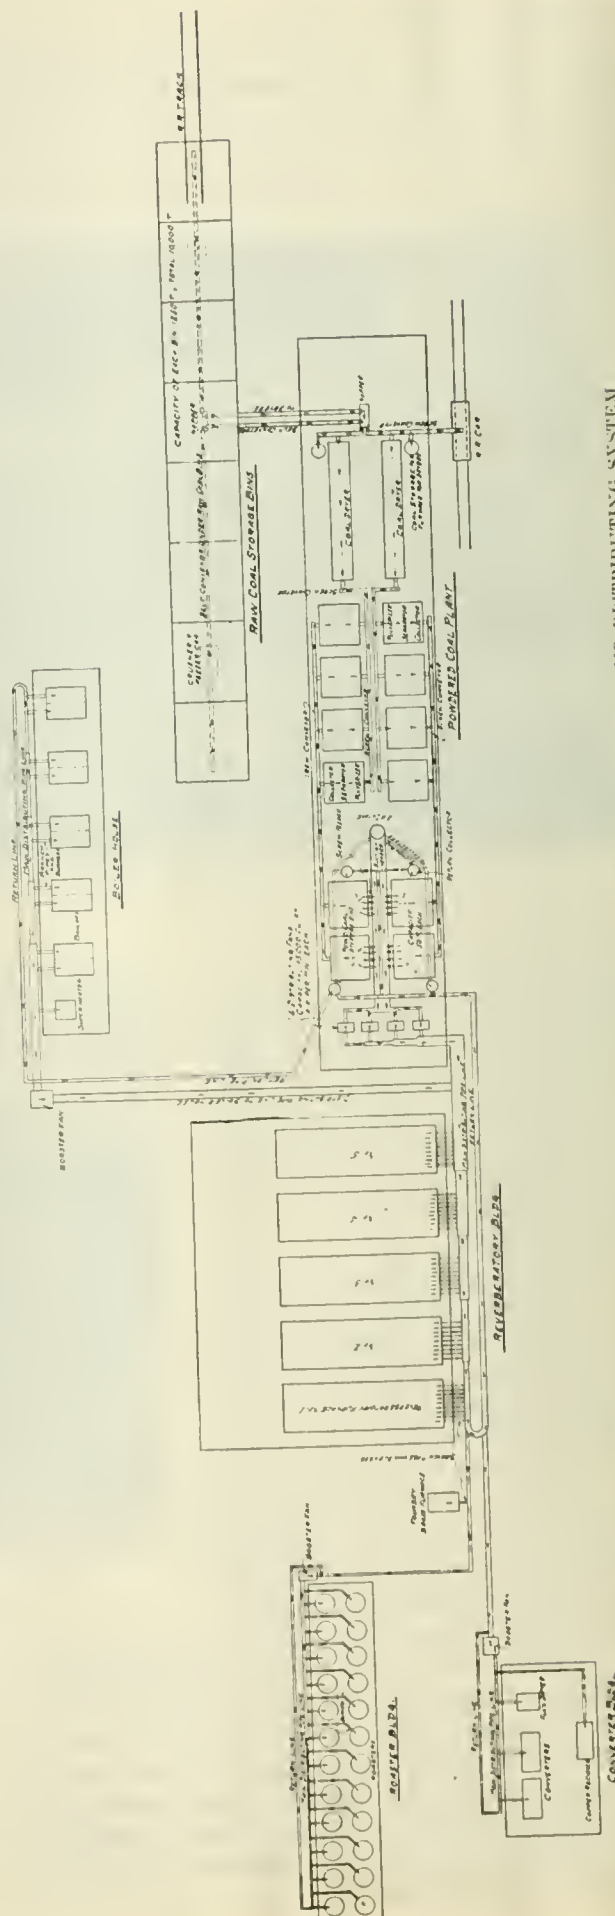

FIG. 2. DIAGRAM SHOWING THE FLOW OF COAL THROUGH THE PULVERIZING PLANT AND DISTRIBUTING SYSTEM

*A. I. M. & M. E., No. 158, Section 28.

"The suction-header is connected to the auxiliary pulverized collectors, and to the return-line auxiliary collectors, and draws the necessary 'make-up' air from the top interior of the building, through a goose-neck extending up through the roof and down again to the indicator. This header is amply provided with explosion-doors, as the coal mixture is lean and explosive. The 50 to 1 mixture is too rich to explode, and hence this precaution is not needed on the distributing header.

"The distributing fans, receiving the proportioned air and coal through the suction-header, discharge the mixture through the discharge-header to the distributing header. The distributing header leaves the coal-plant

of the total coal fed to the suction-header, depending on the amount of the mixture being taken off by the furnaces. Thus, even though no coal is being taken off for burning, the coal in the 50-ton bins is being constantly turned over, preventing spontaneous heating, so long as the distributing fans are in operation."

The 40-inch distributing header has been tapped and extended to serve the power-house, roaster, and converter plants, respectively, through 20, 12, and 10-in. lines, kept in circulation by means of booster-fans. Fig. 2 shows the flow of pulverized coal to the various portions of the smelter. The original distributing system for the roasters did not provide a return-line; it consisted only

FANS FOR DISTRIBUTING COAL TO THE SMELTER BUILDINGS

and passes along the firing-end of the reverberatory furnaces at a convenient distance from, and above, them. Opposite each furnace, a 7-in. drop-pipe leaves the bottom of the main through a slide-gate, regulating-valve, burner-pipe, and burner, to the firing-wall opening in the furnace. The main distributing header is reduced in diameter after each furnace take-off, in order to maintain the velocity requisite to prevent settlement of the suspended coal dust. After serving the reverberatory furnaces, the header makes a 180° turn upward and backward, returning to the coal-plant the remaining mixture through the return-header.

"The return-header enters the coal-plant and divides into branches which lead to the return-line dust-collectors and to the return-line auxiliary dust-collectors. These collectors are situated above the 50-ton pulverized-coal bins; the coal removed from the mixture is thus returned to be fed again to the suction side of the distributing fans. The quantity returning varies from 10 to 100%

of a 12-in. pipe leading from the end of the main distributing header, with a 41-in. booster-fan 283 ft. from the header and 435 ft. from the roaster-plant. This did not prove entirely satisfactory, however, and a return-pipe has been installed to provide circulation similar to that for the reverberatories, thereby preventing the tendency for coal to accumulate in and obstruct the pipe.

POWER-PLANT. The power-plant at the smelter contains all the equipment necessary for generating electric energy for the mine, mill, and smelter; steam, and low- and high-pressure air for the mill and smelter are also supplied from the central plant. Power is transmitted to the mine at 40,000 and to the mill at 14,000 v. For electric generation there are six units, all operating at 600 v., 60 cycle, and 3 phase. Two of these units are Westinghouse turbines, one having a capacity of 3750 kva. at 3600 r.p.m. and the other 2500 kva. at 3600 r.p.m. Of the four engine-driven units, two are 1500-kw. Allis-Chalmers generators driven by 2250-hp. cross-compound

Nordberg steam-engines. There are two 750-kw. Allis-Chalmers generators driven by cross-compound Allis-Chalmers engines of 1200 hp. All of the turbines and engines are provided with condensing apparatus and auxiliaries.

Air for the converters is supplied by three blowing-engines, these all being of the cross-compound type on the steam-ends. The smallest of these units is rated at 450 hp. and will supply 5100 cu. ft. of air per minute at 60 r.p.m. The second unit is rated at 850 hp. and will supply 13,500 cu. ft. of air per minute at 70 r.p.m. The largest unit, 950 hp., will supply 15,000 cu. ft. of air per minute at 70 revolutions.

Low-pressure air for use in the mill comes from two General Electric turbine-driven centrifugal compressors or blowers. One of these is designed to deliver 20,000 cu. ft. of air per minute against a pressure of 15.2 lb. at

not have individual superheaters; instead, all of the steam leaving them is passed through a separately fired superheater of the Foster type, situated in the power-house boiler-room.

In the power-plant boiler-room there are 10 boilers set in five batteries. Two of these boilers are 575-hp. Stirlings, with Babcock & Wilcox superheaters, and eight are 400-hp. Babcock & Wilcox, four having B. & W. superheaters. Four are provided with grate-stokers for burning slack coal, and four of them have been arranged to burn pulverized coal. The results obtained have been so good that it has been decided to remove the stokers and equip all the boilers for firing with pulverized coal. In the course of a series of trial runs, combustion chambers of different sizes and various types of burners were tried; the arrangement that gave most satisfactory results is shown in Fig. 3. During a period of several

FIG. 3. SECTIONAL DRAWING OF A BURNER FOR POWDERED COAL IN THE BOILER-PLANT

3450 r.p.m., and the other 20,000 cu. ft. against a pressure of 18.9 lb. at 3650 r.p.m. The turbines driving these blowers are designed to operate with high-, low-, or mixed-pressure steam. When operating on low or mixed pressure, the low-pressure steam is received from the discharge of the reciprocating blowing-engines. Two Laidlaw-Dunn-Gordon cross-compound compressors supply air at high pressure.

Steam originates from two sources: at the power-house boiler-room and from the waste-heat boilers in the reverberatory furnaces. The waste-heat plant consists of ten 400-hp. boilers set in five batteries. Eight of these are Stirling waste-heat boilers and two of the Babcock & Wilcox type. By-pass flues and dampers are provided so that either one or both boilers in a battery can be cut out of service for repairs. These waste-heat boilers do

months, 10 lb. of water has been evaporated per pound of coal. The temperature, as well as the carbon-dioxide content of the exhaust gases, has been low, with the boilers operating at 25% over-capacity. The size of the combustion chamber, as shown, together with the 'Bunsen' burner, which decreases the velocity of the coal-and-air mixture entering the furnace and allows intimate mixture of the secondary air and coal, has largely eliminated slagging under the boilers, which has been one of the objectionable features of coal-dust firing in power-plants. The dust that accumulates on the tubes does not adhere strongly and is easily blown by the ordinary steam or air soot-blower. Dust accumulating in the boiler settings is easily removed and sluiced by water through the old ash-launders originally installed for the chain-grate stokers.

Centralized Buying

By Edwin Higgins

In the United States there are 36 associations of purchasing agents, belonging to what is known as the National Association of Purchasing Agents, and embracing a total individual membership of about 3500. These men buy each year approximately \$5,000,000,000 worth of supplies and equipment, including every known article of trade. Not included in the national body is the Purchasing Agents Association of Northern California, with 140 members, the total yearly purchases of which amount to \$600,000,000. These figures are given to substantiate the statement that the idea of organized or centralized buying has been 'sold' to big enterprises in the United States. A recent development of the idea is mirrored in the appointment of municipal and State purchasing agents; in the selection of an official to do the buying for all of the farm organizations of a certain county in Maryland; and, finally, in the recent order by Charles S. Dawes, Director of the Budget, for complete co-ordination of all government purchases and sales, as a measure of economy.

As in other industries, the principles of centralized buying may be adopted with profit by operators of mines. A purchasing department is especially valuable to a corporation operating a large number of properties. Although it might not pay the operator of a single mine to employ a special purchasing agent, it is desirable that the buying be done by one man only. Whether the man be the superintendent, or some other official, he should devote some attention to the art of purchasing.

SOME ADVANTAGES OF CENTRALIZED BUYING. Records of purchasing organizations throughout the country contain ample proof of the following advantages of centralized buying:

Economy: Because of purchases in large quantity, by contract or agreement;

Control of Expense: As a result of standardization;

Expedition of Delivery: Because of close contact with selling concerns, and a knowledge of transportation facilities;

Wider Market Vision: Because of intimate contact with salesmen and the possession of price lists, market reviews, and various periodicals dealing with transportation, labor, and general economic conditions; also because of close contact with purchasing agents in the same and other branches of trade.

An illustration of how some of these elements affect the ability to buy advantageously, is the experience of a Californian organization that was placed in a serious predicament during the summer of 1920 because of the lack of a particular kind of cable that was required to complete the installation of a motor. The electrician was discouraged because he was certain the cable could not be obtained on the Coast and because from three to

four months would be required to ship it from the East. Moreover, at this particular time, no freight was moving in California on account of a strike. It was essential to make this installation; otherwise, the whole plant would have had to cease operation. The manager telephoned to the central purchasing office in San Francisco, he stated his needs, and he asked the purchasing agent to advise him within two hours as to what could be done. In exactly one hour the purchasing agent called him on the 'phone and advised him that he had found the cable in San Francisco, that it would be shipped by boat that night, and that he could secure it the next morning in Sacramento. The result was that this cable was at the plant by noon the next day, less than 20 hours from the time the electrician stated his needs. Without going into details as to how the purchasing agent found this cable, it may be stated that it was the only reel of cable of the type desired that was available in the State. The shipment by water was a bright idea of the purchasing agent and disproved the general belief that it was impossible at the time to secure any shipments whatsoever.

SELECTION OF A PURCHASING AGENT. By far the most important problem in the organization of a purchasing department is the selection of the purchasing agent. The making of this selection is a difficult task, just how difficult may be indicated by a glance at the list of virtues that must be possessed by a successful purchasing agent. He must be resourceful, tactful, alert, honest, broad-minded, keen, and a profound student of conditions in countless lines of trade. He should be easy to get along with, hard to fool, and quick to make a decision.

Wilbur Hall, in discussing the ideal purchasing agent, states, in effect, that he must be a student of human nature, endowed with a strong spirit of co-operation, and a willingness and desire to learn. He must acquaint himself with the methods employed in the enterprise for which he acts, the uses of articles purchased, and the personnel of each department; he must know the products, the methods, and the character of the salesman with whom he deals; he must be a student of local, national, and even world markets; he must keep in close touch with transportation, labor, and general economic conditions; above all, he must know himself and the officials of his company.

In addition to the above requirements, there are certain characteristics that the successful purchasing agent must not have, such as 'swelled head', too much pride, or a tendency toward sharp practice. In short, it appears that the perfect purchasing agent must have all the virtues known to man and none of the defects. Obviously, such a man is not to be found, but there are many who approach this description, and who may de-

velop most of the required virtues by study and experience.

THE PURCHASING AGENT SHOULD DO ALL THE BUYING. The purchasing agent should do the one thing for which he is employed: *the buying*. The proportion of the buying done by him will be an exact measure of the success of his department. The difficulties that he will meet in bringing about conditions whereby he will do *all* the buying depend, to a certain extent, on the nature of the organization for which he is working. In order to discuss the subject concretely, let it be assumed that a mining corporation has established a purchasing department to handle the buying for all operations within a radius of, say, 200 miles. The first task of the purchasing agent is to convince the heads of the various departments that it is not his intention to curtail their authority, nor to interfere with their selection of materials or machinery. He must, by actual performance, prove to them that he can serve them to better advantage than they can serve themselves. This preliminary work is essential, for most men in responsible positions believe, and usually for good reasons, that they are capable of buying their own supplies and equipment. The chances are that the idea of centralized buying is new to them; therefore, it must be 'sold' to them.

It is a simple matter for the president of a company to say, "We will have a purchasing department"; it is another matter to make this department function properly. It cannot be done until the co-operation of the executives is secured; and this requires an abundance of tact and patience on the part of the purchasing agent.

THE RESULTS OF INDISCRIMINATE BUYING. It has been stated that the purchasing agent should do *all* the buying. Let us consider some of the situations that might arise when this regulation is violated. Take the case of the engineer in the central office who wishes to buy a certain piece of machinery. He reasons that he knows more about this particular item than does the purchasing agent and that he is therefore better qualified to buy it. Accordingly, he telephones or writes to one or more salesmen, and is interviewed by them. Finally, one of them receives his order—possibly through the purchasing department. What is the result? The standing of the purchasing agent is injured because the salesmen who were consulted, together with those who hear of the transaction, will assume that it is the engineer and not the purchasing agent to whom they must look. The purchasing department has been used only as a filing department, and because of lack of co-operation on the part of the engineer, the purchasing agent has missed receiving valuable instruction. The engineer has spent a great deal of time that might have been employed to better advantage.

On the other hand, suppose that the engineer had called in the purchasing agent, posted him on the particular details to look up in connection with the required machinery, and requested that prices be secured and tabulated. He might have written a letter for the signature of the purchasing agent, provided that the desired

article was of such intricate design as to warrant such procedure. The least that he might have done would have been to direct that all bids be referred to the purchasing agent.

Had any of these three methods been followed, the salesmen would have realized that they must 'sell' the purchasing agent, and the engineer would have been protected against future loss of time. This educational work on the part of the engineer would better equip the purchasing agent to serve the organization as a whole. All data secured during the negotiations would be on file in the purchasing department and accessible for future use.

Suppose the article in question had been wanted by one of the mine superintendents, instead of by the engineer. A single letter to the purchasing agent should bring the desired results, as against the writing of many letters if the superintendent negotiates direct with the seller. The transaction may be analyzed in the same way as the one cited above, with the purchasing agent in the position of a figurehead. The superintendent is sometimes persuaded to sign an order by a traveling salesman who convinces him that it would be impossible for him to do better through the purchasing agent. Possibly the superintendent will send the purchasing agent a copy of the order. Such a transaction contains all of the objectionable features already mentioned, in addition to furnishing the men at the mine and in the office of the purchasing department some useless exercise in handling and filing copies of the order.

There are cases where direct buying is excusable, but they are few and far between. For instance, the mine superintendent might hear of a chance to buy a large quantity of drill-steel, or some other material, at a low figure. On the other hand, it is possible that the purchasing agent, having his ear to the ground, might know of a still better buy. If there is time for a query to the purchasing agent, it should be made; if not, such a purchase is warranted. There are times when the mine superintendent, operating at a distance from the central office, is able to buy something from a neighboring mine or from a local dealer. Where time is a main factor, purchases of this nature are warranted. Once in a while a particular article can be bought more cheaply by the superintendent than through the purchasing department. Although the purchase by the superintendent may be excusable, he should send all of the data regarding the transaction to the purchasing agent.

CO-OPERATION THE KEYNOTE OF SUCCESSFUL OPERATION. The purchasing agent who uses arbitrary methods, who ignores the beliefs and wishes of those for whom he has to buy, and who assumes that he alone knows what and how to buy, will certainly fail dismally. The engineer, superintendent, or other official who adopts a similar attitude toward the purchasing agent will assist that unfortunate individual in his failure. In other words, there must be toleration and a spirit of give and take, all of which means *co-operation* between the purchasing agent and the company officials. Under such conditions only can a purchasing department be made a substantial success.

The Beginning of the Cyanide Process on the Rand

By Andrew F. Crosse

*In the year 1891, when I had not been long on the Rand, I was asked by a client if I thought that gold was soluble in a solution of cyanide of potassium. Well, at that time I had honestly to confess that I knew nothing about the solubility of gold in alkaline cyanide. Soon after I received an invitation to be present at a trial experiment on the treatment of concentrate by cyanide. The trial was carried out on the Natal Spruit. I walked from my laboratory, which was in Von Brandis street, to Natal Spruit across the bare veld as it was in those days. I remember going into a corrugated-iron shed in which on one side there was a vat with a mechanical stirrer agitating a ton or more of concentrate from the Jumpers Gold Mining company's plant. This concentrate was clean, being, I believe, the product of fine vanners; it was kept in motion by a belt-driven stirrer, and was immersed in a strong cyanide solution. If the belt slipped, as sometimes occurred, the concentrate settled and had to be dug out by kafirs. It assayed between five and six ounces of gold per ton.

Why I mention this first exhibition of the cyanide process on the Rand is to show what a long way we have gone since then. This start began at the wrong end, namely, in treating concentrate, a comparatively coarse product, with a strong cyanide solution. The extraction of gold was not encouraging, and a much better result was obtained after roasting and chlorination. If the gold-recovery company had begun at the other end, and had treated the finest product, the slime, it would have soon tumbled to the fact that finely divided gold was readily and quickly dissolved in an alkaline cyanide solution. But the company was thinking more about the royalty it was about to get from the mining industry than about improving a young and undeveloped metallurgical process. As oxygen was necessary, various patents were taken out that covered most of the oxidizing agents known to chemists; but as there were, as far as I remember, no big lawsuits involved, none appears to have been effective. The oxidizing of a cyanide solution by such a compound as peroxide of sodium was bad practice, as I shall show later on.

Gold, in order to be dissolved, must be available. It was a question of fine grinding; the tube-mill was introduced; improvements in amalgamation were made. Where you have free gold or amalgamable gold in an ore, not to catch it would be like a shopkeeper driving away all his cash customers and only dealing with the credit customers; gold obtained by amalgamation is, to my mind, ready cash.

I was the first to try the air agitation of slime on the

Rand at the time when I was consulting chemist on the East Rand Proprietary; my laboratory was on the hill close to the Driefontein and Angelo battery; a Pöhle air-lift pump was used for lifting the tailing. The idea struck me that air would be suitable for agitation purposes, so I had a connection made to my laboratory for bringing it through a half-inch pipe. I used a small vat with a conical bottom and a tube in the centre; with an ordinary mixture of cyanide solution and slime I obtained a good extraction in a short time. I did not apply for a patent, as I did not consider my process sufficiently new to warrant this. Later on I was told that I might have obtained protection; anyhow I saved the industry money, as a later application for a patent, by another, failed through my evidence. Unfortunately for the trained metallurgist, most of the banket ore requires only simple treatment. It is more a question of the mechanical handling and crushing of large quantities of ore and its reduction to a fine state of division, rendering all the gold accessible. Every young man on a cyanide plant knows this nowadays, but it took some time to find it out in those days. I remember in 1903 on the E. R. P. M. the coarse spitzhuten concentrate was given a three weeks treatment in a special vat; but this extra treatment was useless. Hence the introduction of tube-mills, and a higher production of very fine sand. Having ground the coarse pyritic particles, the gold was readily soluble.

Now the product from most of the mines on the Rand is so clean, not having had time to be oxidized, that the cyanide solution is only slightly decomposed, and very little caustic lime is required to protect the solution. Of course this favorable condition is absent when old tailing or accumulated slime has to be treated. The first metallurgists to handle accumulated tailing had many troubles. The quantity of organic matter and ferrous-ferrie sulphate in some of the deposits was considerable; the use of peroxide of sodium with the cyanide solution did not help matters. Sometimes even today the material can be improved before treatment. I will describe my ideas as to the preliminary treatment of slime that contains oxygen-absorbing materials.

The amount of oxygen in a ton of weak cyanide solution when fully saturated is barely 90 grammes. Therefore, a comparatively small amount of oxygen-absorbing material is injurious, and produces ferro- and sulphocyanides. I have carried out some interesting experiments by shaking up sand with a weak cyanide solution saturated with air, and then determining the amount of oxygen absorbed per ton so treated; I found that one ton of sand treated at the Angelo and Driefontein battery on the E. R. P. M. absorbed about as much oxygen as would be contained in five tons of cyanide solution; under these

*Abstracted from the 'S. A. Mining and Engineering Journal'.

conditions ferro- and sulpho-cyanides were formed.

When slime is agitated by air, the oxygen is replaced almost at once; but some classes of slime, even when freshly collected, can be improved by a special cheap treatment. To put it as tersely as possible, I have found in many cases that the consumption of cyanide can be reduced by a preliminary treatment with a weak alkaline solution of hypochlorite of calcium, care being taken to use less than is theoretically needed, as hypochlorite is a strong cyanicide if any undecomposed hypochlorite be left. I made experiments on finely ground pyritic concentrate from Barberton. By treating this material with a 0.13% KCN solution containing 0.127% CaO, 4 lb. of cyanide of potassium and 5½ lb. of caustic lime were decomposed per ton of ore. A sample of the same concentrate was treated with a weak alkaline solution of hypochlorite of calcium; 2.1 lb. of available chlorine was used per ton of concentrate, and 0.57 lb. of caustic lime. The treated concentrate was washed, and it was found that only 1.3 lb. of cyanide and 2.7 lb. of lime were decomposed. No ferro- or sulpho-cyanide had been formed. A weak solution of hypochlorite of lime in lime-water does not attack gold or pyrite.

I made some tests with pyritic ore, from the Machavie gold mine, with the same results. I also made an experiment on fresh lime from the New Primrose about two and a half years ago. A weak solution of hypochlorite of calcium containing the equivalent amount of free lime was used; the experiment was made with distilled water, and there was no available chlorine left in the solution, and only 0.001% of CaO. The treated slime was then cyanided with a 0.03% KCN solution; there was no decomposition of cyanide. This experiment was successful. The gold was quickly dissolved by agitation; the residue assayed only a trace of gold. I do not pretend that this method is advisable everywhere, but on some of the Far East mines I know it could be used with advantage and also in the outside districts where conditions are favorable.

SILVER cathodes for use in the electro-deposition of copper are cleaned by placing them in contact with pure tin-foil in a boiling 10% sodium hydroxide solution until bright, according to H. W. Doughty and B. Freeman, in the 'Journal' of the American Chemical Society. They are then washed successively with dilute hydrochloric acid, dilute ammonia, and distilled water, rinsed with alcohol, and ignited to burn off the alcohol. The electrolysis is carried out as usual except that the electrode is not immersed in the solution until the current has been switched on. To remove the copper deposit, after the final weighing, the cathode is placed in a wide-mouthed stoppered bottle filled with a 10% solution of trichloro-acetic acid in aqueous ammonia (sp. gr. 0.90) to which an equal volume of water has been added. The copper is removed in 10 min. and the silver electrode is not attacked. Chloroform or carbon tetrachloride may be substituted for trichloro-acetic acid, but in this case the ammonia solution is made from 1 part of ammonia

of a specific gravity of 0.90 and 1 part alcohol. The reaction is slower, and care must be taken that no sulphur compounds are present in the carbon tetrachloride that is used.

Johannesburg's Future

There is nothing so aglow with life as a mining town in the height of a sustained boom, nothing so flushed with hectic excitement, nothing offering such a lure to the adventurous of every race. But also there is nothing so dead as its abandoned husk—

"They say the lion and the lizard keep

The courts where Jamshyd feasted and drank deep."

Coolgardie and Silverton will have been forgotten by most of our readers, yet both were flourishing centres of mining before the near-by towns of, respectively, Kalgoorlie and Broken Hill sprang into fame. Kalgoorlie in its turn is now, and has been for several years past, to all appearances, gradually sinking to decay. What will be the fate of Johannesburg?

More and more the foci of gold mining on the Witwatersrand are moving to the extreme east; and, in a less marked degree, the extreme west of Johannesburg. The question has been asked whether it will one day be eclipsed by Springs, the thriving township of the Far East Rand. By 1930, some have predicted, there will be only two mines—the City Deep and the Crown—still working in the 35-mile stretch of the Central Rand. But even though that should prove to be the case, many authorities have great confidence in the future of Johannesburg as a South African industrial centre, irrespective of its gold activities.

It is true that the Rand, with 35 years of work and an output of gold to the value of about £650,000,000 to its credit, is becoming a fairly old field by all ordinary standards. But just as big mines take 'an unconscionable time a-dying' so do big fields. The first steps have been taken toward important economies in the working of the mines, whose cumulative effect should gradually bring many million tons of low-grade ore at present unworkable back into the region of profitable exploitation. A continuance of such a process would automatically extend the lives of at least some of the old properties of the district.

When all is said and done, however, it is a lamentable fact that on the whole field only two important new mines—the New State Areas and the West Springs—are at present being developed with a view to their joining the ranks of the producers. Until the Union government makes its leasing terms for new areas less stringent and until working conditions give the chance to the capitalist of an adequate remuneration in the case of successful exploitation of fresh ground, the Rand as a field will continue at the best to mark time. Whatever happens in this respect the comforting fact remains that most of the younger mines, particularly on the Eastern Rand, have many years of usefulness and prosperity ahead of them.—'Financial Times', August 13, 1921.

REVIEW OF MINING

ENGELS COPPER COMPANY BREAKS FORMER RECORD FOR PRODUCTION

During August the Engels Copper Co. produced 1,030,000 lb. of copper, 16,000 oz. of silver, and 130 oz. of gold from its property in Plumas county, California. Ore treated during the month aggregated 28,000 tons, with extraction of 86% of the copper in the ore, including soluble copper. Based on sulphide copper, the above extraction was 90%, a record which is fully as good as that of any other company working with similar ore. Development of new ore is progressing rapidly and satisfactorily on the lower levels of both the Engels and Superior mines. Work on the seventh level of the Engels mine has been gratifying both as to quality and quantity of the ore, as compared with the upper levels. The work of driving the new adit on the tenth level of the Engels mine is progressing at the rate of 350 ft. per month. This will cut the orebodies of the Engels mine 500 ft. below the seventh, which is the present lowest level.

REDUCED FREIGHT-RATES AND SMELTING CHARGES BENEFIT PRODUCERS IN BRITISH COLUMBIA

Reductions in freight-rates and indications of reductions in treatment and refining charges are bringing closer the revival of mining among independent operators in the Slocan and other Kootenay districts. The Bunker Hill smelter recently reduced its treatment charges on British Columbian lead ores \$1 per ton. With an assurance of a reduction in the freight-rates on ores and concentrates from Slocan points to Bradley, Idaho, the same to become effective on or before September 15, and with the reduction already effective on freight-rates between Bradley and the Atlantic seaboard, it is estimated that the total charge against British Columbian lead ores will be reduced \$4.55 per ton. This it is hoped is but the beginning. Those interested are looking for further developments not only in respect of the cost but also in regard to the improvement of market quotations.

SURVEY IS MADE OF PROPOSED PORT ON GULF OF CALIFORNIA BY PHELPS DODGE INTERESTS

The extension of the Phelps Dodge railroad from Ajo, Arizona, to tidewater on the shores of the Gulf of California seems certain, says a report from Guaymas in Sonora. Completing a trip of inspection of St. George's bay on the north-east coast of the Gulf of California, the 'Silver Gate', under command of Capt. John Ross, and carrying a party of railroad construction engineers and experts, has returned to Guaymas. The expedition, which was under the management of the Tuscon, Gila Bend & New Cornelia Railroad, was for the purpose of making a sea survey of the proposed tidewater terminus of the new railroad, intended as an outlet for the products of the large copper producers of Arizona. A portion of the proposed line has already been completed and is in operation between Gila Bend, Arizona, and Ajo, Arizona. A distance of approximately 105 miles yet remains to be constructed connecting Ajo and the recently selected terminus site on St. George's bay. Accompanying the party were engineers, divers, marine experts, and underwriters, whose purpose was to ascertain tides, currents, sea-

bottom conditions, and the general engineering features involved in the project.

At St. George's bay it is planned to build terminal facilities, including a long wharf, breakwater, and necessary warehouses and buildings. On account of the high cost of freight for rail shipments, the copper producers of Arizona have undertaken this means to afford them access to water transportation for their copper products. This will afford the nearest water terminal for points as far east as El Paso and would give the El Paso & Southwestern-Rock Island railroad a direct tidewater connection much closer than the port of Los Angeles controlled by the Southern Pacific Company.

'NET VALUATION' TO GOVERN FREIGHT-RATES ON ORES AND CONCENTRATES

Through its decision handed down in the Gold Hunter Mining & Smelter Co.'s case, the Interstate Commerce Commission has set up a barrier against the 'gross value' method of determining freight-rates on ores and concentrates and has prevented the already oppressive tariffs from mounting still higher. Had the Northern Pacific Railway Co., with its associates in the case, been favored with a decision permitting it to fix rates on the gross instead of net value, the path would have been opened for all other roads to make similar moves. The case has been in contest for a long period, it having been two years since the Executive Committee of the American Mining Congress met in St. Louis for the purpose of urging adoption of the 'net valuation', after a tentative report favoring the 'gross valuation' had been submitted by the commission's examiner assigned to the case.

UTAH CONSOLIDATED APPEALS DECISION IN APEX LITIGATION WITH UTAH-APEX COMPANY

The appeal of the Utah Consolidated Mining Co. from the decision of T. D. Johnson, Judge of the United States District Court for Utah, in its case against the Utah-Apex Mining Co., was heard before the United States Circuit Court of Appeals in Denver on September 6 and 7. Judge John E. Garland of Washington, D. C., presided. Attorneys J. A. Marshall of Salt Lake City and William E. Colby of San Francisco represented the Utah-Apex company, and John P. Gray of Coeur d'Alene, Idaho, and A. C. Ellis of Salt Lake City represented the Utah Consolidated company.

CALUMET & ARIZONA IS ABLE TO CONTINUE REGULAR DIVIDENDS

Because it was extremely frugal with its war earnings, Calumet & Arizona is able to continue its regular quarterly dividend of 50c. per share. At the beginning of the copper depression early in 1919, the company cut its dividend from \$8 to \$3 per share annually; in 1920 it paid \$4 per share and since late last year has been paying at the rate of \$2 yearly. Calumet & Arizona is one of the few American copper companies to continue in operation. It has taken advantage of the present situation to keep as many men as possible employed in development work and in filling the smelter beds, which have a capacity of 70,000 tons of ore. Of course,

there is only a limited amount of development work which can be done economically under present conditions, as the cost of maintaining the openings in the Bisbee district is high if too far ahead of mining operations. It is costing the company \$125,000 to \$150,000 per month to continue as at present. This cost, however, is more apparent than real, for the company is getting a good return for the money being spent upon the property in the way of developed ore reserves. Calumet & Arizona has been selling during the current year just enough copper to cover its monthly expenditures and by drawing on its cash reserve it is able to pay without embarrassment the dividend due the twenty-sixth of this month. After the payment of this dividend, it will have in cash and securities, but not including copper inventories, over \$1,250,000.

UTAH STEEL CORPORATION WILL ENLARGE ITS PLANT AT MIDVALE

At a meeting of the stockholders of the Utah Steel Corporation on September 3, it was voted to increase the capitalization of the company from 7500 shares of preferred stock to 50,000 shares, and from 17,500 shares of common stock to 50,000 shares. The company will proceed to enlarge its plant at Midvale, and will install a blast-furnace and accessories at a cost of about \$1,500,000. The company now has a capacity of 6000 tons of steel products per month; this will be increased to 25,000 tons. The company has made a contract to secure its iron ore from Iron county, Utah, and the Salt Lake Route will construct a branch line to handle the product.

DISCUSSION OF PROPOSED TARIFF ON MANGANESE

Decided differences of opinion were expressed, during the Congressional hearings on the tariff bill, by representatives of the independent steel companies and the domestic producers of manganese, regarding the proposed tariff on manganese and magnesite. As a result of the steel men's statements that little or no manganese was being produced in this country, the producers devoted most of their time before the committee to presenting evidence to prove that any minimization of the domestic manganese production was based upon obsolete records and reports, specific instances including the data prepared by the Federal Tariff Commission on the subject.

George H. Crosby, a prominent mining man of Duluth, Minnesota, stated that there is 36,000,000 tons of manganese-bearing ore on the Cuyuna range suitable for use in steel making. He stated that the steel men had ignored these deposits in making their assertions. He pointed out how \$7,000,000 had been spent under war stimulation to develop these mines in Minnesota and that out of 34 mines only two are now operating. Even with normal conditions, he said, these mines will be unable to operate without a tariff.

Charles W. Potts stated that he represents a company that has investigated \$750,000 in Minnesota and Arkansas that will be lost if manganese is not protected. He charged a close alliance between the 'so-called' independents of the steel industry and the Steel Corporation. He made a vigorous attack on the method employed in opposing the manganese tariff, taking strong exception to the statement regarding production. He introduced evidence to show that statements made by the steel interests in efforts to prove a lack of domestic supply of the mineral were based on reports that ignored immense tonnages that could well furnish the country.

John A. Topping, chairman of the Board of the Republic Iron & Steel Co., J. A. Campbell, president of the Youngstown Sheet & Tube Co., and C. A. Buck, vice-president of the Bethlehem Steel Co., were among the witnesses who took the opposite views and urged the committee to reduce the pro-

posed tariffs on alloys. Mr. Topping declared the steel users of the country would be forced to bear an increased burden of \$24,000,000 if the rates of the Fordney bill are enacted. Mr. Buck told the committee the steel industry should not be forced to carry the entire load of furnishing tariff protection for domestic alloy makers in order that they might develop.

THE PRICE OF ALUMINUM

Analyzing the relationship of the tariff to the aluminum industry, Herbert W. Smith, tariff expert for the American Mining Congress, declares that it is a reasonably safe prediction that the price of aluminum will be actually lower to the consumer in this country under tariff protection than it is under free trade, simply because the price of aluminum depends so largely on the quantity of possible production. He emphasized the fact that production will be highly increased through projects now being developed on the Pacific Coast for the reduction of bauxite ore, notably in the Klamath river of Oregon, by electric furnaces made possible by cheap water-power. This will be an important development under a tariff. With a certain amount of foreign sales eliminated, increased production may easily make it possible to sell aluminum at a lower price.

ARIZONA

Clifton.—It is reported that J. P. Hodgson, general manager of the Phelps Dodge Corporation, Morenci Branch, has stated that the boards of directors of the Phelps Dodge Corporation and the Arizona Company, Ltd., have reached an agreement whereby the holdings of the Arizona Copper Co. in the Clifton district are to be transferred to the Phelps Dodge Corporation. The agreement is yet to be ratified by the stockholders of the Arizona Copper Co. at a meeting to be held in Edinburgh, Scotland, some time in September.

Globe.—Mining claims in the Rambo and Quartzsite sections are being examined to determine the available tonnage with a view to the erection of a 25-ton mill to treat chloride ores by leaching.

Hereford.—The Alto Mining & Milling Co., recently incorporated for \$250,000, has taken over several lead-silver properties in the Moctezuma canyon in the Huachuca mountains.

Kingman.—Development now being done by the United Eastern company, on the 300-ft. level of the Big Jim claim, has opened the orebody preparatory to stoping. A tram is to be installed to transport this ore to the mill. The new shaft on the north end of the property has reached a depth of over 500 ft. and is being sunk rapidly. At the 800-ft. level a cross-cut is to be run to the vein and lateral development done.—Equipment for sinking a winze from the 700-ft. to the 1000-ft. level of the United American is now in place and active sinking is to be commenced at once. This winze will be sunk on the ore-shoot that was recently opened on the 700-ft. level.—S. P. Landau has taken over the Red Gap mine situated in the Black Canyon range of the Weaver district and owned by the Charles brothers. The vein is faulted and development work in the past has been difficult.—E. Laferrie has secured an option on the Diana mine at Chloride. The mine is an old producer. The shaft is down 300 ft. and levels have been run at 100-ft. intervals. A large tonnage of ore has been shipped in the past and treated in the Mineral Park mill. The development outlined at present is to sink the shaft to the 500-ft. level and open the old ore-shoot at depth. The ore is silver-gold.

Yuma.—It is announced that W. J. Johnson is to erect immediately a 25-ton mill at his Kofa Queen property in the Kofa mountains 55 miles north-east of Yuma.

CALIFORNIA

Downtonville.—The Brush Creek mine, owned by F. R. Weho and F. L. Cole, has been bonded to the company operating the Kate Hardy mine, at Forest. The location is between Goodyear Bar and Mountain House and the property is regarded as having great possibilities. It is estimated that in order to reach the orebody at depth a tunnel 2500 ft. long will have to be run; this is already under way.

Gold-bearing gravel, believed to be a branch of the main channel, has been uncovered in the White Bear mine. The gravel pans well and work has now started for the purpose of tracing the gravel to the main lead. Prospecting for the channel has been in progress several months. Several years ago the channel was mined profitably but the lead was lost and efforts to recover it have failed heretofore.

Georgetown.—Gold bullion to the value of \$10,000 resulted from a clean-up at the five-stamp mill of the Grit mine, at Spanish Dry Diggings. Walter King, who is superintending operations, declares that the company is milling high-grade ore.

Hayden Hill.—The organization of the Hayden Hill Consolidated Mining Co. has been completed, and the promoter, H. P. Anderson, is preparing to start work on the properties. These include the Blue Bell, the Coyote, and other claims not far distant from the Juniper, in which remarkable finds have recently been made. The Blue Bell was opened in 1867 and the records show that it produced a total of \$125,000, mostly on the surface. The shaft is to be sunk deeper. Anderson's associates in the company are N. V. Wemple, George N. McDow, and Russell Brownell.

Jackson.—Capacity operations will be resumed shortly in the Kennedy mine. The ore will come principally from the 3900-ft. level, although the lowest workings are 4165 ft. deep. The ore is free-milling, averaging about \$7 per ton in gold. The property is equipped with a modern 100-stamp mill, which was shut-down nearly two years ago when the mine was flooded to extinguish a fire. It is announced that 17,000 tons of tailing from the old chlorination works have been sold to the Selby smelter. The tailing can be used to advantage in fluxing other ores.

Randsburg.—John M. Fox, superintendent for the California Rand Silver company, reports that stoping has been started above the 450-ft. level, immediately south of the Grady lease, the ore broken being of good grade. The stope above the 9th level, south drift, continues to produce its regular tonnage of shipping ore. A new raise has been started from the south drift on the 10th level, the grade of ore improving somewhat as the raise advances. The No. 2, or new working shaft, was sunk 21 ft., making the total depth 335 ft. Production of smelting ore has been maintained at 10 cars, averaging 44 tons each.—On the Silver Reef No. 1, a shaft is now being sunk near where the diamond-drill had been operating; the diamond-drill has been moved over to Silver Reef No. 2 and is under full headway.—Bisbee and Brey have started a cross-cut at 450 ft. In the meantime the Sullivan diamond-drill, on the 4th level, has reached a point 200 ft. east. The station at 400 ft. is well ventilated, lighted, and equipped for the drillers in charge of the electric drilling machine. A $\frac{3}{4}$ -in. core is taken. At the Silver Moon lease sinking is still progressing; at 112 ft. in the bottom of the shaft a stringer, apparently a gold-bearing stringer, has come in.—The Silver Bar lease is improving; assays show \$20.67 in gold with no silver.—A sample shipment of silver ore from the Hicks lease, on the K. C. N. claim, has been sent to the smelter. Errecart and Lombard, on the same claim, are making good headway in sinking.

Redding.—The Little Nellie mine near the Mountain Copper Co.'s Iron Mountain mine has been shut-down by the Pittsburg Gold Mining Co. Only watchmen are left on

duty. The only quartz mining operation in Shasta county is a new 2-stamp mill near Buckeye, which has been started by George W. Dix and John Grigsby on pocket-ore from the Ida Hiatt mine. The results exceed expectations.—The Shasta Zinc & Copper Co.'s smelter at Ruby Hill is closed temporarily pending the construction of a refining furnace. It is found that the zinc-oxide produced is not quite white enough. J. C. Kinnear, smelter superintendent for the Nevada Consolidated Copper Co., has succeeded R. L. Beals as superintendent for the Shasta Zinc & Copper Co.—Construction of the Mountain Copper Co.'s tram from the Hornet mine to Matheson, the new town on the Southern Pacific, is being rushed. Five towers are in place. The tram will be ready for operation by January 1.

Sutter Creek.—A. S. Howe, superintendent of the Central Eureka mine, has let a contract for sinking the shaft, which will be deepened 200 ft. The bottom of the shaft is in slate, showing numerous flat quartz stringers which are well mineralized. These stringers dip westward toward a gouge-vein lying behind the shaft on the 3900-ft. level, the present lowest level of this property, and there is a possibility that this gouge-vein may carry ore at greater depth. During August the mill crushed 3136 tons of ore, yielding more than \$42,000 in gold.

Tuolumne.—The Sunny South and Wallace claims, commonly known as the Bacigalupi mine, have been bonded to Charles Rives and S. M. Westwood. Systematic development will be undertaken.

COLORADO

Black Hawk.—Settlement made on a 20-ton shipment of ore from the Ross lease, on the Frontenac, by the American Smelting & Refining Co., was at the rate of 2.92 oz. gold, 17.97 oz. silver, and 4.9% copper. Ten tons of mill-ore returned 17 oz. gold on the plates and 11 tons of concentrate assaying 2.28 oz. gold and 9.96 oz. silver.—The Mountain Chief shaft on Tip Top mountain at Apex, is being re-timbered. The property prior to the silver slump in 1893 was operated at profit, but has long remained idle.

Cripple Creek.—Bulkeley Wells, of the Metals Exploration Co., has been elected a director of the Cresson Consolidated Gold M. & M. Co. and Golden Cycle Mining & Reduction Co., succeeding Irving T. Snyder, formerly vice-president and general manager for the Vindicator Consolidated company. The association of Bulkeley Wells with the Carlton interests is significant, in connection with the report that Eastern financiers are said to have undertaken to finance deep-mining operations in the district.—Oliver H. Shoup, associated with Ralph D. Brooks, vice-president of the Midwest Refining Co., William D. Waltman, Rodney J. Bardwell, and Lester S. Grant, have taken a 5-year lease on the Ajax properties on Battle mountain and have commenced work. Thirty-five lease applications have been filed; five sets have started work on ground allotted and a score more will be in operation within ten days.

An important surface discovery has been made by lessees of the Free Coinage Gold Mining Co. at the Pinto mine, on the summit of Bull hill. A new vein has been opened at shallow depth on the west line of the property with specimens showing sylvanite and free gold. Assays run in the hundreds of dollars.—A rich ore-shoot has been opened at the 13th level of the S. Burns shaft of the Acacia company, adjoining the Free Coinage group on the west and south, by the Le Brun Leasing Co. The ore was found on a junction of the Eagle and Wilson veins.

The output of the mines in the Cripple Creek district for August, as shown by the reports of the mill managers, totaled 39,508 tons of an average value of \$10.42 per ton and a gross value of \$411,792. As compared to the figures of the preceding month an increase is shown of \$117,211.

The total production for the months of January to August, inclusive, is \$3,649,472 and the total production to date \$409,418,177.

Georgetown.—Operations have been resumed at the Silver Plume tunnel and at the Bellevue-Hudson mine.

Ouray.—Four sub-lessees of the Barstow mine have about 15 cars of smelting ore mined, and are in receipt of returns on two cars that netted \$8000 each. The third car is estimated at \$10,000 and the entire 15 cars are expected to return around \$100,000 net. The shoot continued for 100 ft. in length. The Barstow Mining & Milling Co. ceased operations about 8 years ago and the property is under lease to its former manager, Clifford R. Wilfley, who with sub-lessees has taken out in excess of \$150,000 since the company ceased operating.

Telluride.—August shipments totaled 140 cars of concentrate as compared with 95 cars for the same month last year. The mills shipping were Smuggler Union, 80 cars; Tomboy, 55; and Liberty Bell, 5, this being from the clean-up prior to shutting down.

IDAHO

Coeur d'Alene.—The West Hunter Mining Co. has drifted 150 ft. from the main tunnel and attained a vertical depth of 800 ft. One selected sample yielded 12% lead and 26 oz. of silver per ton. The drift should enter the ore-shoot in 100 to 125 ft. This vein is the You Like and there is 6000 ft. of it. The company has 1100 ft. of the Morning, or north vein, which parallels the You Like, and is 500 ft. distant. —Lessees in the upper workings of the Gold Hunter are reported to be mining rich silver ore.

A rich find has been reported in the Cedar Creek Mining company's property in the Murray section. The Cedar Creek is an old property in which a cross-cut 2500 ft. in length was driven to the vein. Drifting has been in progress all season and the vein followed for about 750 ft. Recently a shoot of high-grade silver-lead ore 18 in. wide was uncovered in the face, assays from which gave returns of from 50 to 60% lead and 25 to 31 oz. silver.

Development on the property of the Sterling Silver Mountain mining property, on Big Creek, has been resumed, according to Matt Baumgartner, secretary. A cross-cut has been driven about 600 ft. and will be continued 200 ft. farther to reach the main vein which lies at a depth of about 400 feet.

According to reports funds to finance the Northside Railway Co. will be raised. The Northside railway will be about 10 miles long, connecting Prichard, where connection will be made with the Evanville-Prichard branch of the O.-W. R. & N. and the historic town of Murray, for three years shut off from railroad communication with the outside world. Tributary to the proposed railway lie such well-known mining properties as Jack Waite, Blue Bird, Lead Crystals, Columbus, Ironsides, Terrible Edith, Aulbach group, Buckeye Boy, Giant Ledge, Monarch, Paragon, Bear Creek, Cedar Creek, Sabina, Phoenix, and C. & R.

MICHIGAN

Houghton.—There has been shipped out of the Lake district by boat so far this season, 22,880,000 lb. of copper, divided as follows: May (including a few days in April), 5,310,000 lb.; June, 5,858,000; July, 6,536,000; and August, 5,176,000. For the same period in 1920, the total was 37,668,000. In addition to water shipments, probably 7,000,000 lb. has gone out by rail, making the total approximately 30,000,000 lb. This compares with an estimated production for the five months of 23,000,000 lb. Usually at this time of the year, when navigation is drawing to a close, copper shipments increase. The reverse is true this year, however, less copper having been shipped in August than during any previous month of the season of navigation. The August

figures show a falling off of 1,360,000 lb. from the month of July. In August 1920 (the total copper shipments by water were 16,860,000 lb., an increase of nearly 7,000,000 lb. over July of that year.

When operations are resumed by Calumet & Hecla, one of the first projects to receive attention will be the haulage drift or level, at 8100 ft., in the conglomerate branch of the property. This drift was about 80% completed when mining work was suspended. It will be pushed through as rapidly as possible, for once opened it will serve to reduce greatly the cost of mining at this depth. The level will serve all of the conglomerate shafts, which, with the exception of the two terminal shafts, No. 12 and the Red Jacket shaft, will eventually be closed. Not only will this drift enable the company to mine out the shaft-pillars to advantage but it will make easier the task of mining the ground below the level, of which there is still a great volume. It requires at least 15 years to take out the pillars in a single shaft. In No. 8 shaft this work has been under way for 10 years and there is approximately five years more work to be done.

MONTANA

Butte.—The management of the Butte & Superior Mining Co. reports that in cross-cutting south on the 2200-ft. level it has just cut a streak of copper ore assaying 7.6% copper for the first two feet; the following four feet assays 6%, and the following 12½ ft. assays 3.3%, which gives an average for the vein of 18½ ft. of 2.6% copper.

NEVADA

Goldfield.—The Silver Pick has opened a full face of \$32 ore in the cross-cut to the vein in the lease on the Red Top. This proves the ore-shoot for 110 ft. on the dip of the vein below the third level. Little work has been done in the cross-cut since the ore was found, as the miners have been cleaning the chutes from the fourth level of the Red Top down to the second of the Laguna. These chutes are caked with waste, which will have to be removed before the ore from the cross-cut can be put in them. The ore-bins now contain 100 tons of ore of an estimated value of \$40.

Gold Hill.—The United Comstock Mines Co. is making rapid progress in its construction program. The past 30 days has witnessed remarkable strides forward on the American Flat at the portal of the haulage-tunnel. Pouring of concrete has been started from the 140-ft. tower, the mixed concrete being carried direct to the foundation forms for the fine-ore bins by means of chutes. Crushed rock and sand is prepared at the plant on the hillside east of the railroad, and is carried from that point by gravity tramway to the mixer, situated at the foot of the tower. By this method 125 yards of concrete can be handled every eight hours. The upper section of the excavations for the coarse-crushing plant of the 2000-ton mill is now nearing completion and at the lower end forms for concrete are being put in place. Frame-work on the carpenter shop is up and to the west of the tunnel portal, the lodging house, mess hall, and general office building will be ready for occupancy in about two weeks. These buildings are modern in every detail, the rooming house having shower baths, and club room in connection. The cook- and dining-house will have its own electrically driven laundry and refrigerating plant. The office building will house the general offices of the company as well as the engineering staff. Underground, records are being made in driving of the haulage tunnel, the portal end now being in about 2400 ft. It is expected to make the connection with the Knickerbocker shaft heading about the first of the month. This tunnel, through which ores will be transported to the mill from the mines, is now about 70% completed.

Hornsilver.—The ore-shoot on the 580-ft. level of the

Orleans mine has been opened for a length of 300 ft. The vein strikes south-east and dips north-east. There is on this level a cross-cut from the shaft and drifts north-west and south-east from the cross-cut. The North-west drift is the centre of the vein. The work on this level up to a short time ago was done by J. W. Dunfee, former holder of the lease and option and from whom the Orleans Horn-silver company acquired the mine. Before Dunfee started drifting south-east, he turned south to the foot-wall of the vein from the north-west drift and then he drove for 170 ft. on this wall, disregarding the opposite wall because he had found all of the ore on the upper levels on the foot-wall. At the 170-ft. point he drove a cross-cut to the centre of the vein and found ore. From the 170-ft. point he continued the drift south-east in ore for 130 ft. Now the Orleans Hornsilver company has driven three cross-cuts from this 170-ft. length of the south-east drift, each entering the shoot and indicating that Dunfee paralleled it for 170 ft., he driving on the foot-wall, with the shoot in the

company has started mining of the rich vein on the 1000-ft. level of the Halifax, opened by the Oshund lease.

All of the State police that were sent into Tonopah during the strike have returned to Carson. The last few of the officers left recently.

Tule Canyon. The Silver Hills is employing only three or four miners and a foreman at the Ingalls, merely enough to comply with the terms of the option. It is reported that the San Francisco men interested in the company will soon be in Tonopah to consult with W. H. Mereer, who, with Mrs. W. A. Ingalls, owns the mine. It is understood the company is considering abandoning the work at the Ingalls.

OREGON

Kirby. Some high-grade gold ore has been found by Mansfield and Lofland, of Williams, Oregon, on the headwaters of Lightning creek, 15 miles west of Kirby. A 35-ft. shaft has been sunk showing gold all the way down. In early-day mining more gold was taken out of the Lightning Gulch diggings, than any other district in this region. This

Gold Hill, Nevada. Dumps of the Imperial Mine in the Centre

centre of the vein. The three new cross-cuts have opened ore as follows: No. 1, 6 ft., \$6 ore; No. 2, 8 ft., \$20 ore; and No. 3, 4 ft., \$30 ore. The 130-ft. length of the south-east drift is in ore varying in width from 4 to 15 ft. and of an average value of \$30. Sinking of a winze from this 130-ft. length has been stopped at the 50-ft. point, with the bottom in \$30 ore. The fifth level is being continued in a 3-ft. width of \$45 ore and in addition to this there is a 3-in. width on the foot-wall that assays \$400. The next work of the company will be to sink the shaft 100 ft., continue the south-east drifts on the fifth and sixth levels, raise from the sixth level, and explore the vein on the levels above the fifth. It is thought that some of the drifts above the fifth level are not in the vein and at no place has the vein been cross-cut from the foot-wall. Goldfield and Tonopah men are seeking options on ground near the Orleans, but the owners are holding out for impossible prices on the strength of the ore on the bottom level of the Orleans.

Tonopah.—Operations throughout the Tonopah district are normal. Every mill in the camp is running at capacity with heavy shipments of custom ore being made to Millers. Record bullion shipments are being made by the West End and Tonopah Belmont companies, with the Tonopah Extension, Tonopah Mining, North Star, and others increasing production. Late developments in the North Star are said to be important. Lessees on the Montana, Midway, Halifax, and other properties are mining good ore. The West End

new property is about 25 miles west of the famous Boswell mine recently re-opened.

Selma. The Myrtle gold mine nine miles below Selma, owned by Frank Hobart and B. W. Fowler, has been re-opened. Over 100 tons of ore running \$50 in gold is on the dump ready for milling. A 3-ft. vein is opened with 400 ft. of drifts. New equipment will be added.

Talent.—A large body of ore has been uncovered in the Shorty Hope mine, an old-time producer recently re-opened. —The uncovering of a large body of ore, rich in platinum, on Anderson creek six miles out from Talent is also reported.

UTAH

Alta. At the Alta Tiger mine, which lies between the Emma and Flagstaff properties, 10 in. of high-grade silver-lead ore has been opened, according to David Phillips, manager. Samples of the ore show returns running from \$2 to \$140 in gold, from 19.6 to 153.6 oz. in silver, and from 17.5 to 41.4% in lead. As the ore is picked down it will average about \$86.50 per ton.

Big Cottonwood Canyon.—Ore is being hauled steadily from the Woodlawn Mining Co.'s ore-bin to the railroad terminal. A shipment of 53 tons made recently gave average assays of \$1.45 in gold, 45.78 oz. silver, and 12% lead. The gross value was \$51.04 per ton and the net value \$34.60, or \$1824 for the lot. The deposit from which ore is being mined is in fissure No. 2, in a raise connecting the

fifth and sixth levels, according to W. J. Lawrence, manager.

Bingham.—It is rumored that the Bingham Galena Mining Co. has entered into negotiations to acquire the Lost Packer mine in Custer county, Idaho, which property is controlled by the James Ivers estate of Salt Lake City. From 1904 to 1915 the Lost Packer produced about \$800,000 worth of metal. The property is equipped with a smelter of 100 tons capacity, and produced a matte averaging 45% copper, 25 oz. silver, and 8 to 10 oz. gold per ton. Since the death of James Ivers in 1915 the property has been idle. A statement from the management was to the effect that about 20,000 tons of ore was in sight, averaging about \$5 per ton. A 50-ton oil-flotation plant was constructed in 1915, but was operated for only a short time.

Eureka.—The Water Lily shaft at the Chief Consolidated mine is now down a distance of 700 ft. It is expected that sinking will be continued until the water-level is reached, when drifting will be started. The north-east drift on the 1600-ft. level of the Iron King mine is now in quartz formation; ore is expected shortly. N. W. Roberts, superintendent, has put on a second shift to speed the work.—Shipments for the week ending September 3 totaled 155 cars, as against 161 cars for the preceding week. The Tintic Standard shipped 39 carloads; Chief Consolidated, 38; Dragon, 12; Victoria, 11; Grand Central, 11; Eagle & Blue Bell, 10; Centennial-Eureka, 8; Iron Blossom, 7; Swansea, 5; Bullion Beck, 4; Iron King, 3; Colorado, 3; Sunbeam, 2; Eureka Mines, 1; and Gemini, 1.

A party of mine operators recently visited the prominent mines in this district, under the direction of Imer Pett, general manager for the Eagle & Blue Bell Co. The party included L. S. Cates, D. D. Moffat, and H. C. Goodrich, of the Utah Copper Co.; G. W. Lambourne, president of the Judge allied interests at Park City; and A. G. Mackenzie, secretary of the Utah Chapter of the American Mining Congress. It was the first trip Messrs. Cates, Lambourne, and Moffat had made to this district.

Fish Springs.—Production is to be resumed at the Carnation mine, according to announcement made by T. E. Wessel, who will have charge of the property. Recently a new deposit was discovered that contains a high-grade silver-lead ore that averages from 35 to 40% lead and about 250 oz. in silver; it has a low silica content and an excess of iron. Shipments will be made by trucks to Gold Hill, 36 miles north of here, and thence by way of the Western Pacific to Salt Lake valley smelters. The Fish Springs district is noted for the high-grade ore it produced. From 1890 to 1914 the old Utah mine shipped ore that averaged 128.35 oz. in silver and 44% lead, and had a gross value of \$1,580,186.

Moab.—Andrew Nylund and associates recently made a shipment of 40 tons of carnotite ore which netted them \$20,000. The ore came from the Gateway district, south of here, and was sold to buyers at Montrose, Colorado. Mr. Nylund is now engaged in prospecting for carnotite in eastern Utah and western Colorado.

Park City.—Exploratory work in connection with the recently discovered high-grade silver-lead-copper orebody in the Silver King Consolidated mine is proceeding slowly, owing to trouble with water. The ore-shoot has a width of 3 ft., and average returns are about \$200 per ton.—Ore shipments for the week ending September 3 totaled 1914 tons, an increase of 536 tons as compared with the previous week. The Silver King Coalition shipped 771 tons, Judge companies, 705; and the Ontario, 438.

Salt Lake City.—At a meeting of the directors of the Utah Copper Co., on September 8, a dividend of 50c. per share was declared, payable September 30. This will call for a total of \$812,245 and bring the grand total up to \$114,758,632.

WISCONSIN

Cuba City.—The National Zinc Separators are now running full time, and shipments of high-grade water-white acid to Eastern points are being made daily. Receipts of raw zinc ore which furnishes the acid-making base have been increasing recently and run from 350 to 500 tons, weekly.—The Zinc Hill Mining Co. is advertising the sale of its big stock of coal at \$5 per ton f.o.b. mines, which would indicate that this company does not intend to resume mining for some time.

Highland.—Local co-partnership companies are operating on sub-leases of the New Jersey Zinc Co., searching for deposits of carbonate-zinc ore, with fair success. About 1000 tons of this class of ore is available for shipment.

Livingston.—The Yewdall mine is operating with a large force; from 350 to 400 tons of 25% zinc concentrate is produced weekly. This is delivered to the sulphuric acid plant of the National Zinc Separating Co., at Cuba City. The high-grade residue blende is piling up; 66° Baumé is bringing \$18 to \$20 per ton, f.o.b. maker's works.

Platteville.—The Savage-Menke Mining Co. has opened a deposit of lead ore and is producing steadily. A specimen found recently weighs 20 lb., and is crystallized in perfect cubes.

The Zinc Roofing & Products Co., composed of leading zinc operators of this field, is meeting with exceptional success in promoting the expansion of the metal industry by extensive use of its products valuable in the building trades. The State government is a recent acquisition and contracts have been entered into for the use of zinc shingles and corrugated zinc in repairs to buildings at State institutions and for those that may hereafter be constructed.

Higher prices for lead ore, late quotations going as high as \$55 per ton for 80% ore, is stimulating many miners out of employment to secure leases in old lead mines.

WYOMING

Cheyenne.—Two 400-barrel oil-wells have just been brought in by the Sinclair Consolidated Oil Corporation's Wyoming subsidiary. This announcement was first official admission that the Sinclair company was actually operating in Wyoming fields though it was known that the Wyoming subsidiary existed. The company has now about 1200 bbl. production per day available in the Salt Creek field and seven wells in the Osage, Wyoming, field. The two new wells are in Salt Creek field on a 160-acre lease, which is considered one of the most valuable in the State. It is entirely proved territory, and one of the Sinclair wells on this lease is said to have produced an average of about 500 bbl. daily for a year. Active development on the property has been delayed until recently when the lease was approved by the Secretary of the Interior.

BRITISH COLUMBIA

Alice Arm.—The North Star has made a shipment of 90 tons to the smelter at Anyox. As development proceeds this property increases in promise and there are indications that it will become one of the regular shippers of the district.

Cranbrook.—MacKenzie & Mann has given a bond on the Stemwinder mine, at Kimberley, to the Federal Mining & Smelting Co. The Federal company had an option on this property in 1917-'18 and did a considerable amount of diamond-drilling before relinquishing the option. It probably has been re-attracted to the property by the splendid development of the Sullivan mine, which last year provided more than 90% of the zinc and nearly 70% of the lead output of the Province. Though the terms of the bond have not been announced, it is likely that better terms have been obtained, as during the term of the previous bond zinc was selling at about 10c. and lead at about 8c. per pound, and

Porcupine.—It is officially announced that new ore has been found on the seventh level of the Dome Mines, but in the light of present information its connection with the large orebodies on the tenth level is uncertain. The workings are being carried below the tenth level in connection with the extensive plan for exploration adopted, but the depth of the shaft has not been decided on.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Harvey S. Mudd is on his way to London.

Philip Wiseman is playing golf at Del Monte.

H. C. Perkins expects to go to Italy in November.

Charles H. White writes from Missoula, Montana.

Seeley W. Mudd is residing temporarily at Berkeley.

C. V. Corless sailed from Montreal for England on August 19.

Welton J. Crook is in Oregon examining deposits of iron ore.

Louis D. Bontoon has returned from Colorado to New York.

Willet G. Miller has been visiting the Sudbury district of Ontario.

A. H. Wethey, now a resident of Paris, was in New York recently.

A. W. Newberry has returned to New York from Cleveland, Ohio.

W. H. Emmons is here from Minneapolis, on his way to Manchuria.

A. H. Brooks, of the U. S. Geological Survey, is at Anchorage, Alaska.

Elmer M. Bray has moved from Los Angeles to Grantsville, Nevada.

A. C. H. Gerhardt is developing the Homestake claims on Alice Arm, B. C.

G. A. Swanquist has returned to Canon City, Colorado, from San Francisco.

J. Parke Channing has returned to New York from an inspection in Arizona.

W. S. Brainard, of New York, was recently at the Derry Ranch Dredging Co.'s mine, in Colorado.

George Otis Smith, Director of the U. S. Geological Survey, has returned from London to Washington.

Alexander Richardson, Principal of the Camborne School of Mines, in Cornwall, was in New York recently.

Robert F. Lafferty, manager for the Derry Ranch Dredging Co., of Leadville, Colorado, is at Sacramento.

Fred Cowans, general manager for the Utah Consolidated Mining Co., at Salt Lake City, was at Denver recently.

G. H. Dowell, general manager for the Phelps Dodge Corporation, has returned to Bisbee from a visit to the Mesabi Range.

Heath Steele was elected president of the Compañía Minera de Peñoles, in place of K. B. Heberlein, who has resigned.

J. S. Diller, of the U. S. Geological Survey, has completed his field-work in the Lassen Peak area and has returned to Washington.

H. Earl Havenor, geologist to the Tintic Standard company at Eureka, Utah, has resigned and will open an office at Salt Lake City.

John F. Sleeper has moved from Tenafly, New Jersey, to Santa Barbara, where he will establish a laboratory for chemical research.

J. Nelson Nevius has accepted a temporary appointment as instructor of geology in the California Institute of Technology at Pasadena.

Charles A. Banks, of the British Canadian Silver Corporation, has been visiting the Salmon River district, near the Portland Canal, B. C.

A. J. Underwood, manager for the Lluvia de Oro Gold Mining Co., at Lluvia de Oro, Chihuahua, Mexico, has been in California for a month.

H. Foster Bain, director of the U. S. Bureau of Mines, is

expected at Salt Lake City on September 28. A banquet in his honor will be given by Utah mining men on September 29.

E. F. Birch, of Eureka, Utah, for the past twenty years manager of the various Knight properties in the Tintic district, has resigned. Hugh Trenholm will succeed him as manager.

Emmet D. Boyle, Governor of Nevada, announces that he will withdraw from politics at the expiration of his term, and resume the practice of his profession as mining engineer. He has entered into a partnership with W. E. Hindrey, with headquarters at Reno.

Obituary

W. B. Shackelford died at Chicago on July 9. In him the Tri-State zinc and lead region lost one of its leading and most helpful citizens. Recognized as the dean of the zinc operators, Mr. Shackelford had had long experience in this region, and the knowledge thus gained, supplemented with a natural ability to understand men and get to the heart of things, made his assistance in organization work particularly valuable. He was a member of the American Zinc Institute and in the early months of its existence gave much of his personal time and attention to its growth and development. Kindly of heart, broad of vision, he knew personally most of the employees of the companies he managed, and it is an eloquent tribute to his memory that nowhere will sadness over his death be more poignant than among these workers. Always taking an active interest in the welfare of his employees, he was one of the originators and one of the first presidents of the Southwest Missouri Mine, Safety, and Sanitation Association, which had its headquarters at Webb City. Later he helped to found the Oklahoma-Kansas-Missouri Safety and Sanitation Association, which ultimately became the Tri-State branch of the American Zinc Institute, with headquarters at Picher, Oklahoma. He was born at Rockville, Indiana, in 1862; he was married to Luella Richt, of Platte City, Missouri, in 1889. He was not an old man, but his death after months of suffering from a dangerous malady was not unexpected.

Anthony F. Lucas died at his home in Washington on September 2. Captain Lucas, as he was generally known, achieved fame twenty years ago by sinking the oil-well that became the Beaumont gusher of 1901, thereby starting the Spindle Top oilfield of Texas. He was born at Trieste, Austria, in 1855, and came to the United States in 1879. In our issue of December 22, 1917, will be found an interview covering his career, which was marked by great energy, keen intelligence, and unswerving integrity. In youth he was an officer in the Austrian navy, but, being a Dalmatian by birth and of pure Montenegrin descent, he took an early opportunity of leaving an uncongenial service in order to join an uncle in the United States. In 1885 he became an American citizen, and throughout his subsequent career he proved himself one of the highest type. His son served with distinction in the A. E. F. during the recent war. Captain Lucas was a man rich in enthusiasm for right ideas; he was a hard worker and an intrepid pioneer of industry, particularly in the development of the salt and oil deposits of the Gulf region, in Louisiana first and then in Texas; also in Mexico, where he was associated with Sir Wheetman Pearson, now Lord Cowdray, in the development of the Tampico oilfield. He traveled widely and was an unusually well-informed man. Of a cheery and kind disposition, bubbling over with good-nature and high spirits, he was beloved by a host of friends, who now mourn his sudden death. In him 'Americanization', a much abused term, found fitting expression; he was a good citizen, a loyal friend, a kind father, and a devoted husband.

EASTERN METAL MARKET

(By wire from New York)

September 12—Copper is quiet and stronger. Lead is quiet and higher. Zinc is inactive but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46 65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MR. FORD'S "RAILROAD MIRACLE"

The railroad miracle which Henry Ford is supposed to have wrought by converting within a few months the Detroit Toledo & Ironton from a deficit incurring property to a profit earning railroad has been discussed according to the current issue of the Railway Age, not to say change in method of operation but primarily to an increase in the average freight rate per ton per mile.

During the four months September to December 1920 inclusive, after the present railway rates were fixed the D. T. & I. handled an average of 49,246,000 ton miles of revenue freight per month and had freight earnings averaging \$493,800 per month. In the months of April, May and June 1921 the road handled an average freight business of 37,993,000 ton miles per month and earned from it an average of \$604,900 per month. In other words its average freight business in these three months was almost 25% less than in the last four months of 1920, while its average monthly freight earnings were over 10% greater.

This large increase in freight earnings in spite of a big decline in the total freight handled could have been due to only one cause, and that was an increase in the average rate. And there was a very extraordinary increase in its average rate per ton per mile—a thing to which public attention never has been called before. In the last four months of 1920 its average rate was one cent per ton per mile. The average rate per ton per mile in April, May and June 1921 was 1.88¢, or 88% greater than in September, October, November and December 1920. The average rate of all the railways in the country is only 1.2¢.

To what was this remarkable increase in the average rate per ton per mile due? Chiefly to two things. First to a great change in the character of the traffic handled. Mr. Ford began giving his railway practically all of his freight business, and the freight handled directly and indirectly for his motor works consists largely of relatively high grade commodities which pay a rate much higher than the average. Meantime the amount of coal handled by the railroad greatly decreased. Coal being a bulky and cheap commodity it pays a rate much smaller than the average. This change in the character of the traffic alone would have caused a large increase in the railway's average rate.

Secondly, the D. T. & I. has been able to use a large volume of traffic originated by the Ford interests to secure larger divisions of the through rates of all traffic handled partly over its line and partly over other railways, and the great bulk of the D. T. & I.'s business consists of this through traffic. Both the change in the character of the traffic and the larger divisions of the through rates obtained by the D. T. & I. have tended to increase its average rate per ton per mile, and the only really great change which has been made on the D. T. & I. up to July 1 was in the contract rates which determined its average rate per ton per mile.

But how about the reduction of 20% in its local rates and the advance in the wages of its employees which were so widely advertised? Neither of these were put into effect until July 1 or later, and therefore neither of them had anything whatever to do with the increase in the railway's net earnings which we have been so widely expounded. We shall have to get later data than are available before anybody can say what is the effect of these changes in important policies.

MONEY AND EXCHANGE

Foreign quotations on September 12 are as follows:

Sterling dollars	Cable	3 73 1/2
Demand	3 74 1/2	
Franc cents	Cable	7 28
Demand	7 30	
Mark cents	Demand	4 33
	0.96	

Eastern Metal Market

New York, September 7.

The general buying power has changed little; prices are in some cases stronger. The Labor Day holidays have also had their effect.

The elimination of most of the cheap copper has strengthened the market. Inquiry is good but buying not heavy.

The tin market is firm with moderate buying.

Prices of lead have been advanced; buying is steady.

The zinc market is stronger but demand is not heavy.

Antimony is unchanged.

IRON AND STEEL

An upward turn in output, after nine months of steady decline, is shown in the pig-iron statistics for August. The total was 954,193 tons, or 30,780 tons per day, against 864,555 tons in July, or 27,889 tons per day. Taken in connection with the larger buying of mid-August and the firmer tendency of prices, this increase in output confirms what has been said recently of a slight improvement in consumption.

While there was a net gain of but one furnace last month, the larger yield being due to the operation of many stacks at a better rate than in July, the outlook is for further improvement in September. Seven furnaces have either started since the first of the month or are scheduled to start before September 15.

The capacity of the 70 furnaces in blast as the month came in was 30,770 tons per day, against 28,175 tons per day for 69 furnaces on August 1, based on their performance in July. The gain of one furnace followed the loss of no less than 250 furnaces from the active list in the preceding nine months.

The slight upturn from the long decline in pig-iron prices made consumers cautious. Buying has been less active in the past fortnight; at the same time considerable inquiry is up and the balance between supply and demand is being closely watched in view of the starting of a furnace here and there.

COPPER

The tone of the market has improved perceptibly. Prices are firmer and there are less offerings of low-priced lots. This is due to the turn of the month and is analogous to the situation which has prevailed in the last two or three months. At the end of each month there have been offerings of weakly held lots which have caused prices to ease off at the close of each month, followed by a firmer market at the beginning of the new month. Electrolytic copper cannot be bought at less than 11.75c., New York, or 12c., delivered, for early delivery with most large consumers out of the market at this level or refusing to entertain less than 12.25c., delivered. Inquiries are moderately brisk and a better buying market is anticipated as the month progresses.

TIN

The market continues moderately active with prices tending higher. The London market continues strong and higher with prices about £5 per ton higher yesterday than a week ago; the market on this side is also advancing. Spot Straits, New York, was quoted at 27.25c. yesterday or 1c. per pound higher than a week ago, while spot standard in London was £16 15s. yesterday, future standard at £163 15s., and spot Straits at £162 per ton. Buying in the past week was moderately brisk on one day with dullness characterizing most of the other days. This was on Thursday, September 1, when the monthly tin statistics revealed a larger delivery into consumption than was expected. About 300 tons was sold to two or three dealers on that day. At

the close of the day there were more sellers than buyers and since then the market has been quiet because of the holiday. Deliveries into consumption in August were 3320 tons with 1761 in stocks and landing on August 31. Imports in the first 8 months of this year have been 12,978 tons against 36,688 tons to September 1, 1920.

LEAD

Last Friday, September 12, the American Smelting & Refining Co. advanced its price 10 points to 4.50c., New York and St. Louis, and this was followed by independent interests except that the latter quote 4.30 to 4.35c., St. Louis. The market is firm and there is a quiet steady demand. There is also some demand for future lead and sales for this position have been fairly good at premiums over the above prices of \$2 to \$3 per ton.

ZINC

The disappearance of the weaker offerings has resulted in a firmer market. Prime Western cannot be bought at less than 4.20c., St. Louis, or 4.70c., New York, for early delivery as against 4.12½c., St. Louis, a week ago. Demand has not improved so far as buying is concerned though there is a little business each day. The better tone pervading all the markets and business in general is having some effect in this case.

ANTIMONY

The market is dull and unchanged with wholesale lots for early delivery quoted at 4.50c., New York, duty paid.

ALUMINUM

Virgin metal, 98 to 99% pure, in wholesale lots for early delivery is quoted at 24.50c., f.o.b. plant, while importers are asking 19 to 20c., New York, for the same grade.

ORES

Tungsten: There is no life to the market and quotations are nominally unchanged at \$3, and up, per unit in regular concentrate.

Ferro-tungsten is inactive with quotations for the American alloy nominal and the imported product quoted at 36.50 to 40c. per pound of contained tungsten.

Molybdenum: There is no activity and quotations are unchanged at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: Foreign high-grade ore can be bought as low as the nominal quotation of 20c. per unit, seaboard, but there is no demand.

Manganese-Iron Alloys: German ferro-manganese, 76 to 80%, is quoted at 4930 marks per ton, seaboard, which is at least \$5 per ton less than the British product at \$65, seaboard. Demand is light and the only sale noted is one of 50 tons of domestic alloy, quoted at \$70, delivered. Two carloads of spiegeleisen are reported sold at \$26, furnace, for 20% alloy.

Production of crude-oil in Mexican fields for the first two weeks of August was 4,519,000 bbl., according to a recent report. Estimates for the entire month are an output of 8,000,000 bbl. This production compares favorably with that of July, the first month in which shipments were drastically curtailed. July output was in excess of 300,000 bbl. per day, about 50% below the normal average for the first six months of the year. Peak average production was reached in May, 560,000 bbl. per day. Oil in storage in Mexico has increased materially. Oil men will venture no estimate of the amount of oil in storage, but the capacity is now considerably in excess of 50,000,000 barrels.

Book Reviews

The Metallurgy of the Common Metals. By L. S. Austin. John Wiley & Sons, Inc., New York. 615 pp., ill. For sale by the 'Mining and Scientific Press'. Price, \$7.

This is the fifth edition of a treatise that was first produced in 1907, and is devoted to a description of processes for the recovery and purification of the common metals, which in this case comprise gold, silver, iron and steel, copper, lead, and zinc. The metallurgy of iron is treated only to the point where pig-iron is produced. Since 1913, the date of issue of the last edition, radical changes have been made in metallurgical practice; the present edition has been re-written to a large extent to bring it up to date. The chapters dealing with gold and silver were written by Mr. M. W. von Bernewitz, and the chapter on zinc by Mr. R. G. Hall. Under the subject of general metallurgy the following topics are treated: ores and metals; fuels; refractories; preparation of ores; crushing, grinding, screening and classifying; metallurgical furnaces; combustion; metallurgical thermo-chemistry; roasting; concentrating of ores as a subsidiary operation in metallurgy. The discussion on 'gold' includes: gold ores and classification for milling; amalgamation; hydro-metallurgy of gold ores; chlorination of gold ores; cyanidation of gold ores; typical gold-mill practice; treatment of concentrate; various treatments and calculations; smelting gold ores. The treatment of the subject of silver includes silver ores and their occurrence; the amalgamation of silver ores; silver milling in hydro-metallurgical practice; cyanidation of silver ores; parting gold-silver bullion. There is a chapter on iron ores and their smelting, and another on wrought iron and steel. The treatment of copper includes a discussion of copper ores; blast-furnace smelting of sulphide ores; reverberatory smelting; converting copper matte, the hydro-metallurgy of copper; the refining of blister copper; and electrolytic copper refining. A chapter on the properties of lead and its ores is followed by others on silver-lead smelting; products of the blast-furnace; production of lead ores and prices; refining of lead and base bullion. Under the subject of zinc there are chapters on roasting zinc ores, the smelting of zinc ores, and zinc refining. The concluding chapters of the book deal with plant, equipment, costs, and the business of metallurgy.

The distribution of wealth in the United States is considered as a preliminary to a study of the economics of engineering. The labor situation is discussed, with particular reference to the mining industry. The tyrannical power of labor unions is emphasized. Figures are given to show that a financial crisis may be expected in the United States either in 1926 or in 1927. It is suggested that the mining, smelting, and milling industries should unite to form a union; an executive committee would outline a form of propaganda. Such an association should use the lock-out judiciously and should prepare for the shut-down. Even as the union man will strike and starve to gain his end, the author says, so must the company do, confident that by such lock-outs a permanent improvement can be made.

Under the title of 'Organization and Operating', Professor Austin deals with the organization of a metallurgical company. The divisions of the administrative department are given, and the scope of each is detailed. The duties of the various officials in the operating department are defined; and a list of 'Rules of Work' is appended. Plant operation and the morale of inside men are considered, followed by an analysis of the various modes of payment in vogue. The financial aspect of the matter is dealt with under 'Capital Requirements', which is followed by an analysis of the work of the accounting department. The subject of profit and loss is considered in the final chapter. The book covers a

wide field and contains much that is not found in other treatises on the subject.

Concentration by Flotation. Compiled and edited by T. A. Rickard. 6 by 9 in., cloth, 692 pp. John Wiley & Sons, Inc., New York. For sale by the 'Mining and Scientific Press'. Price \$7.

The American engineer is particularly favored in the wealth of information given by the technical journals of this country. The rapid development of our technical industries has been largely facilitated by the free interchange of methods and ideas. The editor of a technical journal renders a great service to his fellows when he persuades investigators and operating engineers to place the results of their work before the world promptly through the technical press. He renders a second and very vital service when he collects, edits, and publishes in compact and readily consultable form the papers that give a comprehensive view of the latest developments of any branch of engineering.

The flotation process of concentrating ores has had a phenomenally rapid and important development. The whole mining world is indebted to T. A. Rickard, as to no other individual, for keeping the public informed as to the development, perfection, and application of this valuable process. Mr. Rickard has written much upon flotation himself, and has persuaded many of the engineers engaged in the development and application of the flotation process to describe the results of their work in the columns of the 'Mining and Scientific Press'. He has published two previous compilations under the titles of 'The Flotation Process' and 'Flotation'. These were issued by the 'Mining and Scientific Press' and the editions are now exhausted. The present volume is a compilation of articles appearing in the 'Mining and Scientific Press' during the years from 1915 to 1920, and includes, in addition to articles re-printed in the previous volumes, eighteen articles that have appeared since the publication of the later of the two earlier compilations.

'Concentration by Flotation' will be useful to all who are interested in the most modern work in concentration, as it contains a glossary of the terms used in flotation literature, a history of the development of the process, a discussion of the extensive patent litigation accompanying the introduction of the process, together with numerous articles on the physical and chemical principles involved in flotation concentration, descriptions of the numerous applications of the process to the treatment of different types of ores, and detailed instructions for testing ores by flotation. The gathering together of these many articles into a single volume makes them readily available for use by the teacher, the student, and the operating engineer. In the course of time we may expect Mr. Rickard to persuade others to contribute further to our knowledge of the technique and theory of flotation concentration, and again gather together a book bringing the subject up to some later stage of development. At the present, 'Concentration by Flotation' contains more valuable information on this subject than is presented in any other single volume. J. M. H.

The Handbook of Standard Details. By C. H. Hughes. Pp. 312, illus. D. Appleton & Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$6.

This book was compiled especially for engineers and draughtsmen, so that drawings, tables, and formulae of standard details might be available in convenient form. All who are in any way interested in the subject, and this includes all mining engineers, will find it invaluable. The contents are as follows: Drawings; Fastenings; Power Transmission; Pipe, Tubes, and Fittings; Rope and Chain Fittings; Miscellaneous Details; Structural Details; Useful Tables.

Company Reports

LUCKY TIGER COMBINATION GOLD MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills at El Tigre, Sonora, Mexico.

Operating Officials: R. T. Mishler, manager; E. J. Stanley, mine superintendent; W. A. Wasley, mill superintendent.

Financial: Concentrate sales, \$3,405,489.96; operating costs, \$1,870,011.30; general income, \$58,875; general expenses, \$107,376.59; net realization from operations, \$1,486,981.47; consolidated net profit, \$792,201.76; dividends, \$1,323,373.45; to date, \$7,469,572.89.

Development: 11,218 feet.

Production: 76,212 tons was milled, producing 6746 tons of concentrate, assaying 2.78 oz. gold, 433.31 oz. silver, 3.9% copper, and 14.05% lead. The extraction by concentration amounted to 96%, as compared with 94.2% during the previous year.

General: Increased efficiency is shown in the mining work, the output per man-shift having increased from 0.45 ton in 1919 to 0.64 ton in 1920. The increasing amount of zinc in the ore constitutes a metallurgical problem. It renders the ore less desirable for smelting and has been the cause of repeated increases in the smelting charges. The removal of the zinc at El Tigre by electrolytic methods is rendered difficult by the high cost of power and the low price of zinc. Experiments are being continued in the hope of solving the problem.

MINING CORPORATION OF CANADA, LTD.

Report for the year ended December 31, 1920.

Property: Mines, mills, and cyanide plant in Canada; owns the Cobalt Reduction Company.

Operating Officials: C. E. Watson, manager; M. F. Fairlie, mill manager.

Financial: Gross income, \$1,693,065.47; total cost, \$1,041,603.74; surplus as at December 31, 1920, \$3,268,628.53; dividends paid during the year, \$622,518.75.

Development: Ore-reserves, 103,603 tons containing 2,181,000 oz. silver.

Production: 51,918 tons milled for a production of 1,664,018 oz. silver as compared with 1,239,653 oz. during the previous year.

General: Active search was made during the year for new properties; three hundred received consideration, of which, in the case of 165, permanent records were prepared. The purchase of the Buffalo mine was completed. The corporation owns a large interest in the syndicate having under option the Flin Flon property.

GUANAJUATO REDUCTION & MINES COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mill at Guanajuato, Mexico.

Operating Officials: H. P. Smith, general manager; A. McDonald, mill superintendent.

Financial: Receipts, \$1,478,053.85; disbursements, \$1,490,175.65; deficit for the year, including bond interest, \$58,794.71.

Development: 5935 metres of new levels and raises driven in the Mother Vein mines. Ore-reserves amount to 233,145 tons of mine-ore blocked-out, with 219 grammes silver and 2.55 gm. gold per ton; and 483,113 tons of ore on dumps, with 158 gm. silver and 1.20 gm. gold per ton.

Production: Tonnage milled, 217,074; production, 35,618.95 kilogrammes of silver and 431,154,614 gm. gold.

General: A further reduction in cyaniding costs was made at the Flores plant, the expense being \$1.0909 per ton, as compared with \$1.2029 in 1919.

NEW YORK & HONDURAS ROSARIO MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill in Honduras.

Operating Official: A. R. Gordon, general manager.

Financial: Operating income, \$1,511,735.01; operating expenses, \$1,125,196.19; operating profit, \$386,538.82; New York administrative expenses, \$67,498.26; balance carried to surplus, \$211,667.54; surplus as at December 31, 1920, \$1,403,204.39; dividend, \$320,000; amortization, \$80,000; dividends and amortization to date, \$5,790,000.

Development: 16,838 ft.; ore-reserves, 211,783 tons containing 16.32 oz. silver and 0.067 oz. gold.

Production: 140,100 tons was treated for a return of 1,711,349 oz. silver and 8001 oz. gold; average silver recovery was 86.07%; gold recovery, 94.52%.

General: Tests made with the idea of introducing flotation have been unsuccessful. A new Dorr thickener was erected during the year.

SILVER KING COALITION MINES COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mill in Utah.

Operating Officials: M. J. Darley, manager; Forrest Mathez, superintendent.

Financial: Total income, \$1,056,041.55; expenses, \$644,952.15; net profit to surplus, \$358,359.61.

Development: 8974 feet.

Production: 14,517 tons of first-class ore, sold for \$807,862.24; 25,103 tons of second-class ore, producing 4568 tons of concentrate that was sold for \$198,825.03; 1849 tons of lessees' ore sold for \$116,957.88, producing royalty amounting to \$36,723.92.

General: A new flotation unit of 100 tons capacity was constructed and almost completed when fire occurred early this year, destroying the entire plant. It has since been decided to replace the mill with one of a capacity of 450 tons per day.

ROUND MOUNTAIN MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mill in Nevada.

Operating Official: Gibson Berry, general superintendent.

Financial: Total revenue, \$106,922.74; total operating costs, \$122,855.52; net operating deficit, \$15,932.78.

Development: Round Mountain Mining Co., 2006 ft.; by lessees, 2139 feet.

Production: placer operations, 64,665 cu. yd. gravel was hydraulicked for a recovery of \$56,277.37; lode and lode-leasing operations, 4513 tons was mined and milled for a yield of \$21,377.96.

General: It is stated that during 1921 the debts of the company will be greatly reduced if not entirely liquidated. Most of the difficulties have been surmounted; conditions are more favorable for gold mining, as far as the company is concerned, than has been the case for many years.

GREENE CANANEA COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Mines and plants in northern Mexico.

Operating Official: T. Evans, general superintendent.

Financial: Income, \$7,299,918.84; expenses, \$6,380,314.67; balance, \$560,078.50; dividends, \$1,000,000.

Development: 76,431 feet.

Production: 1,053,806 tons of wet ore was produced; the yield amounted to 43,672,939 lb. copper, 1,778,617.56 oz. silver, and 10,089,584 oz. gold.

General: Since the introduction of flotation at Cananea it has become evident that the flow-sheet can be simplified and cost of concentrating reduced. Plans are being prepared for the necessary changes.

T. A. RICKARD, Editor

ANOTHER technical society has been formed and is gaining a representative membership. We refer to the Society of Economic Geologists, of which Mr. J. Volney Lewis is secretary, with Mr. R. A. F. Penrose as president and Mr. Edson S. Bastin as vice-president. The economic geologists are a scholarly and widely-traveled group of men; they should be able to establish a useful and interesting association.

WE have received a letter from a subscriber asking whether a certain process would suit his ore, which, according to wet assays, contains gold and platinum, but which yields no precious metal when subjected to the fire-assay. This is an old story; in this case, as in others, it indicates chicanery, fakery, spoofery, trickery—in short, lying for a purpose. If an ore yield no gold or platinum by fire, and if the assay be made by a competent person, it may be taken for granted that it is not an ore in the technical sense, that is, it cannot be exploited at a profit for gold and platinum, because we know of no mineral containing these elements that will not surrender its valuable contents when treated with flux and fire under conditions that have proved sufficiently effective in the past.

DISCUSSION this week starts with a letter from Mr. Walter X. Osborn, who writes from Arizona to protest against the excessive price of articles made of brass. It is to be hoped that the newly organized Copper and Brass Research Association will take note of this. The purpose of the Association, of which the principal copper operators are members, is to stimulate the use of copper and brass. One way to do so is to prevent the imposition of extortionate prices on articles manufactured of copper and brass. Mr. Leon A. Perret writes from Yokohama on the subject of black sand, that is, the treatment of the heavy concentrate obtained in the course of placer mining. His suggestion to use the Berdan pan reminds us of the days when that little grinding machine was much in vogue in stamp-mills, for the treatment of the heavy sand and pyrite saved on blankets. Another criticism of the proposed revision of the mining law comes next, from Mr. A. G. Blackburn. A tunnel-driving record is claimed for the Hetch Hetchy engineering project by Mr. F. C. Hickman. From Queensland we have received a letter on the use of producer-gas; the writer, Mr. Erle Huntley, a well-known mining engineer,

sends a useful drawing of a gas-producer that has proved efficient. Another letter on the mining law comes from Mr. Gordon D. Stanley. He also joins with other prospectors in objecting to sundry of the proposed changes. We would like to hear from those who approve of the revision.

THE influence exerted on the magnetic needle by black iron sand was discovered by Mr. Arthur Gibson during the winter of 1905, on the Third Bench near Nome, in Alaska. The increased magnetic variation in the horizontal plane as indicated by a transit-compass when placed over the paystreak was pronounced, and this led him to make a closer investigation. The depth from the surface to the paystreak varied from 25 to 130 feet, and all the overburden was frozen. The common dip-needle held in the hand gave better results than the transit-compass; it was realized that sensitive instruments were needed; two were constructed, one of Mr. Gibson's design. Later, in 1910, it was learned that the Canadian government had been using magnetometers with success in tracing and defining deposits of iron ore, so he sent to Europe for two more instruments, known as the Thalén Tiberg and Thomson-Thalén models; the latter is so sensitive that it will indicate the approach as well as the direction of travel of a street-car that is three city blocks distant from the instrument. On another page of this issue will be found an interesting article by Mr. Gibson, who has familiarized himself with the instruments and their application, and now publishes a valuable contribution to the literature of the subject.

'BUY something made of copper.' To this slogan a recent special issue of the 'El Paso Times' is devoted. A circle drawn through Santa Rita on the east, Jerome on the north, Ajo on the west, and Cananea on the south would include copper mines that produce, in normal times, 60,000,000 pounds of copper per month, which is nearly half of the total output of the United States. The entire territory is largely tributary to El Paso, and although the city is by no means dependent upon mining, that industry is the most important of the surrounding region. A 16-page supplement is composed of articles by prominent engineers engaged with the copper-mining companies in New Mexico, Arizona, and Sonora; among them is an interesting his-

torical article, 'The Romance of Copper Mining', by Mr. John M. Sully, general manager for the Chino Copper Company, at Santa Rita in New Mexico. He describes the first production of copper in New Mexico, 114 years ago. Advertisements of progressive business firms of El Paso accompany the articles; one of them is the Mine & Smelter Supply Company, with whom originated the slogan—practical if not poetic—'Buy something made of copper'.

THE Utah Copper Company finds itself in a peculiar predicament in consequence of the clause in the Federal Railroad Act that requires every railroad company in a particular district to contribute, to a Federal fund, half of its profit in excess of an amount sufficient to yield a return of 6% on its investment. The company owns all the stock of the Bingham & Garfield Railroad Company, over whose line the ore from the mine at Bingham is transported to the concentrators at Garfield. It financed the building of the road; the separate company to operate the railroad was incorporated in order to gain certain conveniences and advantages in the matter of taxation that could not be obtained if the mining company were the nominal as well as the actual owner of the railroad. The railroad company charges the mining company for hauling ore, the profit being paid back to the mining company in the form of dividends. The mining company includes in its annual report the financial statement of the railroad company, and the whole proceeding is a matter of book-keeping. The railroad company became a prosperous corporation; so prosperous in fact that its officials looked with natural distaste at the provisions of the Railroad Act to which we have alluded. Legal strategists were called into consultation, and a contract between the two corporations was signed, whereby the Utah Copper Company obtained the privilege of using the Bingham & Garfield railroad, in consideration of which the mining company undertook to guarantee the railroad company a net return of 6% on its investment, thereby avoiding the possibility of the railroad company being obliged to disburse good money for the support of less profitable railroads in the Western district. Now the Public Utilities Commission of Utah and the Federal Interstate Commerce Commission have undertaken an investigation to determine whether the terms of this contract violate the law.

IN the course of his address on 'Earthquake Engineering', before the Engineers Club of San Francisco, Professor Bailey Willis of Stanford University made a plea for public support in behalf of a proposed appropriation of \$15,000 annually for five years for the U. S. Coast and Geodetic Survey, this money to be used for repeating the observations of the primary triangulation on this coast with a view to measuring the displacement of the surface that is caused by seismic tremors. He made the interesting statement that scientific observations along a particular parallel of latitude around the earth had proved that Ukiab, for example, was moving

north at the rate of about one metre per annum, this being the measure of the displacement along a rift parallel with that which marked the line of the great earthquake of 1906. Earth tremors are due to slippage along a shear-plane at such times as the stress, attributable to the pressure of the sub-oceanic mass against the continental margin, overcomes the friction between the two faces of rock. A major shock, or earthquake proper, usually follows a series of smaller tremors, and marks the culmination of an effort to restore equilibrium—the balance of nature. The Seismological Society of America, of which Dr. Willis is president, is about to issue an engineering bulletin accompanied by a map of the State, showing the principal rifts or faults, in order that the people in general and the engineers in particular may be able to avoid them, especially in selecting sites for buildings or other engineering structures. Along any of these rifts or lines of quake there is danger of further movement; also in 'made' ground near-by, which, during an earthquake, will tremble like a bowl of jelly, because the looser the texture the greater the vibration. It is hoped, by the adaptation of the instruments developed during the War for the detection of the movement of submarines and of marching armies, to be able to obtain a complete record of local tremblings, the growing intensity of which is regarded as the precursor of a bigger shake. Thus it may be possible eventually not only to predict the place but also the time of earthquakes, so that human beings may take steps to escape the ill effects of them.

Copper

The higher quotations for the shares of copper-mining companies indicate the growth of confidence that the period of idleness will come to an end soon. Moreover, it is recognized generally that, owing to the recent curtailment of production, the technical position of the market for copper is improving. In July the output of our domestic mines was 16,390,000 pounds, and of American mines abroad—all of which send their copper to the New York market—23,145,000, making a total of 39,535,000 pounds. The August output is estimated at about the same. Sales during the month are known to have amounted to 70,000,000 pounds. The normal production is about 145,000,000 pounds. For the first seven months of this year the production is estimated to have been 700,000,000; for the remaining five months it is expected to be 200,000,000, making the total 900,000,000 for the current year. Domestic consumption and exports for the first seven months averaged 98,719,000 pounds, or a total of 691,033,920. Assuming the same rate for the next five months, the total for the year could be placed at about 1,175,000,000 pounds. Thus the consumption would exceed the production by 275,000,000 pounds. Shipments abroad during the seven months totaled 331,033,920 pounds, but domestic consumption was low, averaging only 51,428,000 per month. The stock of refined copper in this country on January 1 of this year was estimated at 650,000,000 pounds, and the total

supply available during the current year may be taken at 1,659,000,000 pounds. Therefore the stock of unsold copper at the end of this year should be not more than 384,000,000 pounds. There is a great improvement in the statistical position. In consequence the copper-mining industry ought to start 1922 under excellent auspices. The supplies of scrap brass, cartridge-cases, shell-bands, and other residues from the War are becoming less abundant, and as they disappear there will come an increasing demand for new copper, especially from Europe. The industrial health of the United States is recovering from the depression that came so suddenly last November, and with the revival there will be a broader market for copper.

Institutes and Technical Journals

The latest issue of the 'Canadian Mining Journal' contains a valedictory from Mr. F. W. Gray on his retirement as editor. We have read it with sympathy, for it has a plaintive note. Mr. Gray asserts that it is no easy matter to conduct a national mining paper in Canada because the number of technical men is relatively small and they are scattered over a wide territory; moreover, the mining industry of Canada is small as compared, for example, with that of its big neighbor. He compliments the technical journals of the United States, having in mind, we hope, the mining papers; he says they are "excellent publications, backed by wealthy publishers, and, in recent years actuated by the consciousness of increasing importance in the world relations of the United States, the leading technical papers of that country have shown wide catholicity in their choice of matter, and have indeed taken the world for their parish". This is no small compliment, and in behalf of our contemporaries and of ourselves we thank our Canadian friend for it; but he is in error as to the backing of wealthy publishers. He might be correct if he omitted the 'Mining and Scientific Press', but we believe he did not mean to omit us, because more than once he has expressed a friendly appreciation of our efforts. No wealthy publisher has ever backed the 'M. & S. P.'; it has made its way on its own merits for 61 years. Mr. Gray says, "it is natural that Canadian publicists should avail themselves of the prestige and wide circulation of these American papers", but that makes it just so much harder for the 'Canadian Mining Journal' to obtain the requisite support from subscribers and literary contributors. In one respect, however, the Canadian paper has a slight financial advantage: it receives advertisements from the Dominion government and from the Mining Departments of the various Provinces. The issue before us contains three pages of such advertising. That is a small matter, however; it is poor solace for the inadequate support from the manufacturers of Canada. The apparent lack of success on the part of our Canadian contemporary is due, we venture to suggest, not so much to competition from this side as the trespass made upon its field of activity by the Canadian Mining Institute—which now has a longer

name. The monthly bulletin of this society is a far more readable and more comprehensive publication than the 'Canadian Mining Journal'; it is more attractive and more interesting, and is sold to members at \$1 per annum. The membership of the Institute includes a large part of the clientele that the 'Journal' desires, and among the contributors to the pages of the bulletin are the very men whom Mr. Gray, and his successor, would wish to co-opt. In short, we think that it is not the smallness of the Canadian mining industry, or the inability of the Canadian mining public to support a national paper, that has interfered with the success of the 'Journal', but the trespassing of the Institute upon the field of technical journalism. The Institute is doing excellent work as a publisher on its own account; its monthly bulletin contains a good summary of news from the various mining districts, besides editorial comment and special articles. It has usurped the principal function of a national mining paper. That is why the 'Journal' languishes. The question arises, does the Canadian mining industry gain from the expansion of the Institute's publishing activities when these compete unfairly with the 'Journal'. We say "unfairly" because the Institute primarily is not a publisher, and certainly was not intended to become the publisher of a mining periodical, but is an association for promoting the solidarity of the mining profession in Canada. The extension of its activities into journalism is due in large measure, we believe, to the initiative of its former secretary, Mr. H. Mortimer-Lamb, himself a man of scholarly attainments and wide human sympathy, qualities admirable in themselves but the exercise of which proved unfortunate for the editors of the 'Journal' because they lacked these qualities in equal measure and therefore were unable to meet the competition started by the secretary of the Institute. Its bulletin, of course, is a subsidized publication, that is to say, it is financed indirectly by the members of the Institute; it is not conducted purely on its merits as a commercial venture in journalism. It solicits advertising, and therefore cuts into the revenue that would otherwise come to the 'Journal'.

Let us accept the conditions as they are and assume that the issuance of the Institute's monthly bulletin will render it impracticable to conduct a profitable mining paper in Canada; is such a result desirable or is it deplorable? We ask this question not without a side glance at New York. The subject is one of timely interest and, we believe, of paramount importance. In London, the Institution of Mining and Metallurgy issues a monthly bulletin, but that publication contains no news items and no editorial comment; it is restricted to its proper function, and therefore does not compete with 'The Mining Magazine' or 'The Mining Journal'. It may be said of 'The Mining Magazine', at least, that it fulfills the purpose so well that it need not fear competition from the Institution's bulletin, but it is conceivable that if the latter were to be expanded into journalistic form it might trespass seriously upon the field of the 'Magazine'. The point is that such competition is unfair because these

journalistic activities of the engineering societies start with the advantage of a clientele won through other means, namely, the appeal to professional solidarity in behalf of a professional organization; not for the purpose of publishing a journal but for the purpose of publishing technical papers and more particularly for providing a public occasion at which these papers can be discussed. Now, we ask the members of the mining profession to face the issue squarely: is it to their advantage and to the advantage of the mining industry to approve of the journalistic exuberance of their institutes or institutions if this exuberance have the effect of killing independent journalism? It may be suggested that we need both the professional society and the technical journal each in its own particular field. The societies grew out of the professional spirit developed through the exchange of ideas in the mining journals, which have been their strongest supporters in the past; now the very existence of independent journalism is threatened by an invasion of their territory. The editors of the journals usually have abstained from professional practice, some of them consistently. Does the profession desire the continuance of professional journalism and independent editorial writing, or does it desire to place itself entirely, for good or ill, in the hands of a central committee? We dare to say that the profession and the industry in Canada, in Great Britain, or in the United States, will lose more by killing independent journalism than by limiting the activities of its professional organization, particularly those that seem to involve a surrender of its truly professional character for the sake of commercial gain.

The Inarticulate Subordinate

Reciprocity in the dissemination of interesting and useful information is recognized among mining engineers as one reason for technical efficiency, as well as for the avoidance of economic waste in the duplication of research and experimentation. A man who relies on his own experience and ideas can make little progress. In the current annual report of the St. John Del Rey Mining Company we note a continuation of the policy of obscuring the metallurgical work at the plant in an atmosphere of mystery. The mine is one of the most interesting, and has the deepest shaft in the world. The plan of metallurgical operations probably would be equally interesting if it were disclosed. The product is mainly gold; that much cannot be camouflaged. But when the interested engineer comes to a question of metallurgical practice he is tantalized by the lack of definite information and by vague references to the "first process" and the "second process". Attention is drawn in the report to a concentrating plant, and to "reconcentration strikes and furnaces"; the recovery from this, the "first process", it appears, "has amounted to 70.89% of the total content". In the "second process" it would seem that collecting and stirring-vats are used, but there is no hint of cyanidation; here the recovery of gold represents 20.08% of the total content.

To increase the mystery, the assay-value of the ore is given in 'oitavos'; it is comparatively high-grade. The St. John Del Rey company has not lagged behind in making use of contemporary improvements in technical practice, most of which are available at a negligible cost because of the frank publication of details by those companies and individuals who favor reciprocity and who appreciate their obligations in this respect. The reticence observed by this particular corporation in regard to metallurgical details is not typical of the best English mining enterprise. Recently we made enquiry of Messrs. John Taylor & Sons for technical information concerning the metallurgical operations at one of their mines in India, and our request was met with a spirit of frankness and courtesy, which inspires confidence and encourages co-operation. A mining company should be the first to realize that its annual statements constitute a valuable means of publicity on technical as well as on financial matters; it would be better if the reports of the heads of the mining and metallurgical departments were incorporated therein, so that the reader could appreciate the personality behind the description of work and progress. Although in many instances this may be impracticable, we believe that the plan should be followed to a greater extent than it is. The general manager would be spared the responsibility of sponsoring absurd statements on technical matters on which he frequently possesses no specialized knowledge; we call to mind a report of this kind that came to hand recently and that dealt with a technical problem in a manner that was hopelessly misleading. The second advantage of allowing the superintendents of mine and mill to be heard would be that the statements of those in such responsible positions would begin to reach a wider audience. Initiative and effort would be encouraged if such officials knew that at the end of the year they were to be allowed to state the result in their own language. The publication of such reports would stimulate an appreciation for correct and convincing statement, for concise wording of matter that is of technical interest; it would encourage a desire to succeed, if not to excel. The obligation of the company toward such men does not end with the payment of salary. Higher education should be fostered, and one of the best means to do this is to stimulate adequate self-expression. The best technical book on a well-known subject is always the one that gives credit to those who have gone before, who have blazed the trail and are deserving of credit for pioneer work. This is the scientific spirit; its absence invariably marks a divergence from verisimilitude, if not from truth. The men in charge of mine and mill have 'done their bit' to bring the industry to the state of technical efficiency in which it is today; they should become articulate in the company reports of the year's operations. The general manager who can appreciate this will find that much credit reflects on him for an attitude that bespeaks an appreciation of the work of others, and of a desire for general advance, based on a recognition of the fact that the ability of the individual makes for the efficiency of the staff as a unit.

DISCUSSION

Cost of Copper Products

The Editor:

Sir—I recently received a quotation from one of the largest pump manufacturers, for a telescopic joint for a sinker pump. Their price for a 4-in. by 16-ft. joint, with galvanized inner and outer tube, is \$200. With a brass inner tube, which is much superior, the price is \$550. The weight of the brass inner tube is not over two hundred pounds, so that they are asking a dollar and a half per pound for the brass, as the cost of fabricating a brass tube is not any greater than fabricating an iron one.

This illustrates one of the principal reasons why the copper industry is dead and the principal mines are shut down. As long as manufacturers ask such unreasonable prices for articles made of copper or brass, we cannot hope to see the demand for copper increase very much. A firm dealing in mining machinery has started a campaign in El Paso to stimulate the demand for copper. They have a card printed, 'Buy something made of copper', which they have displayed in a large number of the stores in El Paso. I believe they would accomplish more if they would use their influence with manufacturers to getting prices on copper and brass articles down to a point where they could compete with similar articles made of iron or cheaper metals.

Gold in Black Sand

The Editor:

Sir—The discussion aroused by the interesting information given by Mr. John Gross in your issue of November 27, 1920, and of April 9, 1921, touches a question the importance of which seems not to be sufficiently recognized by the practical placer miner. In fact, a great amount of gold is discarded and lost in the large quantities of black sand that are thrown away daily in almost every locality where gold-placer mining is carried on, owing to the absence of a cheap and simple method of treatment for the clean-ups. Although the combined quantities of black sand obtained on any goldfield is considerable the amount produced by the individual operator at each clean-up is small, and there lies the difficulty in devising a simple and cheap method of treatment without expensive and complicated equipment, such as a combination of classifiers, ball-mills, concentrators, electro-magnetic separators, and the like.

Mr. Holmes, in your issue of May 14, is quite right in asking "Why classify before grinding?" As certified by the experiments of Mr. Taylor stated in your issue of June 18, and by the tests conducted by Messrs. Gross and Davis at the Alaskan station of the U. S. Bureau of Mines, the main feature for successful recovery of gold from black sand is the grinding of the clean-ups, and my own practical experience has led me to the same conclusion. Consequently it all comes to the use of a cheap and simple grinding appliance. Such a one is the Berdan pan, which some thirty years ago was an indispensable part of almost every stamp-battery in Australia and New Zealand. I venture to say that this device will solve the black-sand question, as it meets all the requirements of the ease, doing the grinding and the amalgamation at the same time, and not requiring any particular attendance.

The accompanying sketch shows the equipment. The

BERDAN PAN

pan A and the ball B (about 12 in. diam.) are of ordinary cast-iron and can be made in any foundry. C is a copper-plated amalgamating-table. Mercury is used in the pan, which makes about 18 or 20 revolutions per minute. The incline of the shaft is about 60°. The driving gear is fixed beneath the pan to prevent oil and other greasy substances from interfering with the amalgamation. The pan requires about $\frac{1}{2}$ hp., and that amount can always be taken from any steam-engine or electric motor at work on the mine. Should this not be possible there generally is a ditch or a flume that can supply the water necessary to drive the pan by a miniature over-shot wheel. The cost of installation should not exceed a couple of hundred dollars, I suppose, and the device is simple enough to set up anywhere, even at the most remote placer mines of the interior of Alaska. It could be placed on any dredge. In working, one Berdan

pan can be used to treat the clean-ups of a great many placer mines, and the accounts with each individual black-sand producer could be settled in proportion to the volume, or the weight, of the material delivered for treatment, as in the same locality the gold content in the clean-ups is nearly constant, the nature of the gold being more or less uniform, the same methods of washing being used, and the panning being done with the same skill on all mines in the same district. The error in the accounts thus made should be very slight, I suppose, and this mode of procedure makes matters simpler than cleaning up the Berdan after each separate lot had been treated.

I have used the Berdan pan as described in a number of places in Russia, and in each instance it gave entire satisfaction. I have not the results at hand, but one case I remember distinctly, and that was on the Kolehan mines of the Orsk Goldfields, which at that time belonged to the Okhotsk company, in partnership with Messrs. Nadetzky and Stepanoff. During a visit to these mines in the autumn 1898 or '99, I advised the manager to install a Berdan pan for the treatment of the black sand, and gave him a sketch of it. A few months after the close of the next operating season I received a letter in which the manager thanked me for the good idea I had suggested, and informed me that the output of the mines had been a few pounds in excess of 40 poods (21,080 oz.) of gold. The Berdan had recovered from the black sand additional 28 Russian funts (367 oz.) of gold, which otherwise would have gone to waste. The whole equipment had cost between 400 and 500 rubles.

Yokohama, July 29.

L. A. PERRET.

[Stamp-mill and cyanide-plant metallurgists will find the apparatus described by Mr. Perret of considerable value for cleaning amalgam and for recovering gold from mill refuse and smelter slag.—EDITOR.]

Revision of the Mining Law

The Editor:

Sir—In your issue of June 18 you invite discussion of the proposed new mining law. Following are some objections of mine, approved by all the prospectors that I have discussed the matter with.

Section 5 is impracticable in that it cannot be made to apply to lands of the public survey. Speaking from experience, I would say that in large areas of the mountain States, survey stakes are almost as scarce as gold mines. In the rough and most inaccessible places they probably were never put out; in others they have been knocked down and destroyed by the elements and stock. I recall one instance, of four men, directed by a competent surveyor, working a week trying to find a corner to tie an application for patent, who failed to find one within six miles.

Article B is wrong, as it would enable persons or corporations to locate and hold, at trivial expense, large areas of the public lands for long periods of time without development. The mineral outcrops that smile at one

as they are approached have approximately all been found. Most of the recent discoveries have been made in a trench or shaft dug with a pick.

Article E. A bad one: as it permits even a questionable discovery, made in a drill-hole, to be covered by a patent of 160 acres. Some claim! To us of the hills, it looks like an entail of the mining regions of the West to engineers and mining companies, and in lieu of encouragement to the prospector it would tend to drive him out of the game entirely.

Why not eliminate that part of the old apex act that is objectionable, and give us vertical side-lines? We would then have a law that has stood the test for half a century, with the kick knocked out of it.

A. G. BLACKBURN.

Masonic, California, August 26.

Tunnel-Driving Record

The Editor:

Sir—I read with great interest the article in your issue of the 27th ult. regarding the new world's record for shaft-sinking by the Walter Fitch Jr. Co. As I have done a good deal of sinking myself I think it was great work. I am driving a tunnel now, and I established what I think is a new U. S. record for hard-rock tunnel-driving last month, namely, 776 ft. in schist and quartzite. The work was done at Priest Portal, which is part of the Hetch Hetchy project on the mountain division. Dimensions 11 ft. 3 in. by 11 ft. 3 in. Area of heading 106 sq. ft. An average of 28.3 lb. of 40% gelatine powder was used per foot. Ingersoll-Rand Leyner machines were used, three machines on the bar, and the Myers-Whaley mucking machines were used. Worked three shifts per day, and during the month 38 hours were lost on account of repairs and power failures. Messrs. A. C. Dennis and Fred Wilson are sub-contractors.

F. C. HICKMAN.

Groveland, California, September 4.

Producer-Gas

The Editor:

Sir—A letter by M. W. von Bernewitz in your issue of March 19 prompts me to send you a description of a producer-gas plant that has been in operation for over six years at the works of the Hampden Cloncurry Copper Mines, in Queensland, Australia.

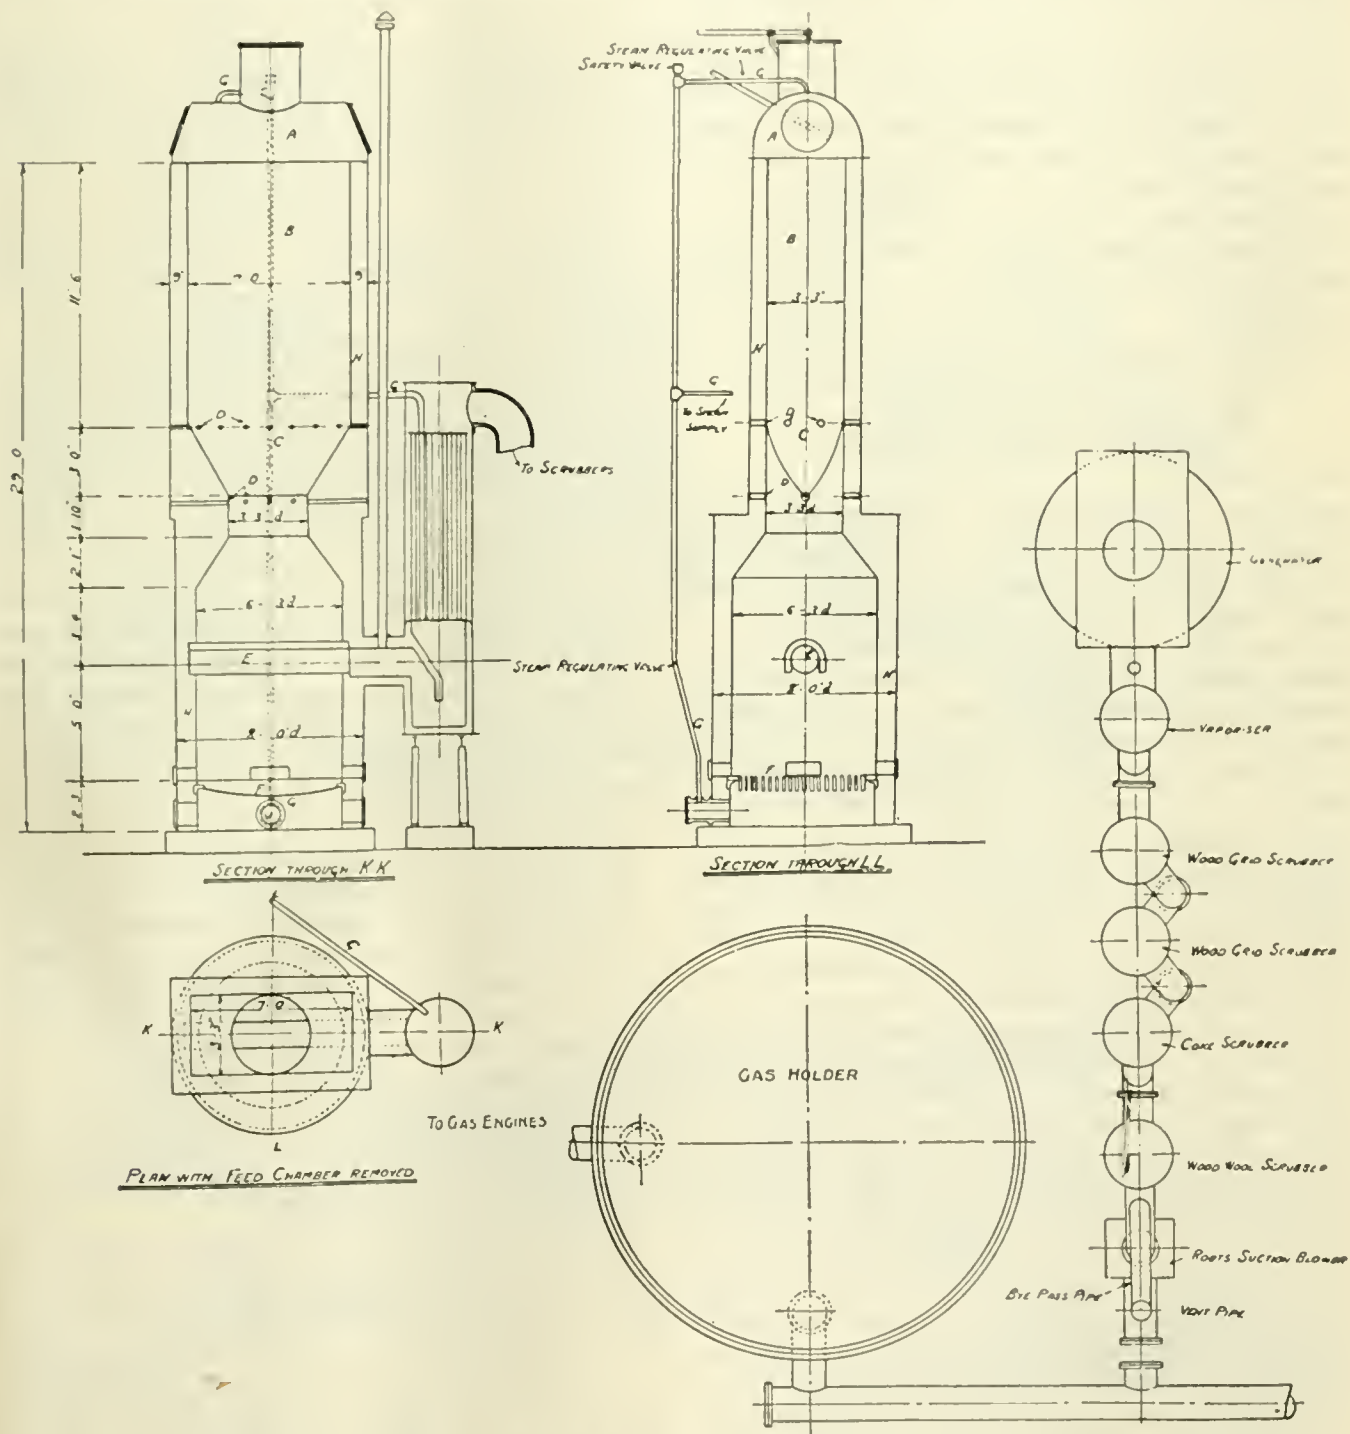

I can safely affirm that for over five years there has not been ten minutes stoppage of power due to defects in the producer or power installation. The plant runs 24 hours daily and 7 days per week.

The engine-plant consists of six engines of an average capacity of 250 brake horse-power each. These drive on a main-line shaft, the power from each driven pulley being transmitted thereto by a friction-clutch. Only four or five engines are used at one time, and, owing to the friction-clutch connection to the line-shaft, any engine can be laid by for overhaul at any time.

The gas-plant consists of three producers, each capable of making gas to develop 800 horse-power. Two of these, only, are used at one time. The fuel used is ordinary cord-wood, cut in 6-ft. lengths, and fed direct to the producer in all kinds of shapes and sizes. The consump-

Two men per shift are employed attending to the producers.

With fire-wood costing 17s. per ton, the cost of fuel per b.hp. is, approximately, 4.8 pence per day, and with labor at 18s. per shift, the cost of labor is 1.7 pence per

HAMPDEN WOOD-FUEL GAS-PRODUCER

tion of fuel over some years has averaged 2.2 lb. per hp-hour, or, say, three pounds per kilowatt; and this weight takes the bark and chips into consideration.

The gas produced has an average value of about 112 British thermal units per cubic foot.

The fuel used contains on an average about 25% fixed carbon.

hp-day, or a total of 6.5 pence per day, or, approximately, £10 per hp. per annum.

The accompanying plan and section gives dimensions and details of the producers in use. Two fires, one at the top tuyeres (D), and the other on the fire-bars (F), are kept continuously burning, the gas from both being drawn off together through a central arch (E), con-

structed of fire-clay or cast-iron. Into the top or feed-chamber (A), the crude fire-wood is fed. As this descends the column (B) of the producer, it encounters the air drawn through the upper tuyeres. This air is regulated to keep a bright fire at this zone. Passing through this zone the oils, hydro-carbons, etc., are decomposed or volatilized, and the wood converted into charcoal. The gas made is drawn down and out through the central gas-vent (E). The charcoal descends past the gas-vent and finally reaches the bottom fire-grate, under which air and steam is admitted as usual, and the carbon is consumed and converted into useful gas, which is drawn up and out through the gas-vent (E).

This producer was designed and built by the staff at the mine, and is known on the market as the Hampden gas-producer.

ERLE HUNTLEY.

Cloncurry, Queensland, June 7.

Revision of the Mining Law

The Editor:

Sir—I have read with much interest the letters of John F. Davis and Emile M. Renaud on the proposed change of the mining law, in the August 20 issue of your valuable paper. Having been a prospector for the last 30 years I feel qualified to pass judgment on at least most of the proposed changes. I have been prospecting and developing goldbearing quartz claims in the upper San Gabriel mining district for the past six years. I and my partner, Ben F. Miller, billed our bacon and beans to the mouth of Iron Fork on the main San Gabriel river, and, armed with a Forest Reserve map, took all the short cuts on foot. The third day after our arrival we discovered a goldbearing vein. Our map showed the country to be surveyed, and some of our locations appeared to be on Section No. 5. As the U. S. law requires the miner to conform as nearly as practicable to the Government survey, we undertook to discover a section corner. Being a practical surveyor and being entirely familiar with all the corners set by a deputy U. S. surveyor on sectionizing and subdividing, I took the map and undertook to find a section corner. After several days of painstaking and systematic hunting I failed to find any evidence of corners or even of lines. A careful inquiry among all the old-timers (some had been on the river for forty years) elicited the fact that they had not seen a corner nearer than 12 to 16 miles. That was in November 1915. After six years residence here and prospecting over every foot of ground, I have failed to find any evidence of Government survey. About two years ago John Hibsch (manager of the H. A. Williams store, at Azusa) representing the heirs of George Trogden, applied for a patent to a placer claim at Iron Fork. He employed a deputy mineral surveyor to survey the claim for patent. He came armed with field-notes from the U. S. Surveyor's office, together with a crew of chainmen and a good compass. After a week or more of surveying he failed to find any Government corners, and was finally compelled to establish a U. S. mineral monument to tie his survey. Mr.

Hibsch or the deputy U. S. mineral surveyor will verify this statement. Oregon and other States have many cases parallel to this.

The laws of the State of California require the prospector to stake, blaze, and record his discovery within 30 days after discovery. Without discussing the right of the State to impose such a law on the discoverers of mineral on the public domain, it is apparent that if a prospector was compelled to hire a U. S. mineral surveyor to establish a mineral monument, and tie his description to it, he would not be able to comply with the State law.

To my mind the most serious objections to conforming to cardinal lines is the fact that veins seldom run parallel to the survey lines. Even if the veins run straight, which they seldom do, it would be impossible to conform to the Government lines and cover the mineral.

Section 5B. Subject to limitations. I fail to understand by what course of reasoning consistent with honesty anyone could advocate the location of mining claims without first discovering mineral, since the law already allows you to prospect as long as you feel justified by indications of mineral. By all means let everyone be compelled to discover mineral in place before he can locate. We already have enough locations without discovery, usually surrounding some prospector who is developing his prospect. The legalizing of this class of locations would furnish many additional annoyances to the bona-fide prospector. It would not help the bona-fide prospector in any way, but, on the contrary, would enable the blanketting of all the mineral belts to the disadvantage of the real prospector, besides legalizing the holding of water sources and timber under guise of mineral locations.

Section 5B. Final C. E. in seven years as the primary object. The law should encourage the discovery and development of mines and not the monopoly of mineral sources. I cannot see any reason for compelling the prospector to patent his claim before he knows it is worth patenting. Under the present law, development continues as long as the assessment is required.

Section 6B. Payment into Land Office in lieu of development work. I think the idea is entirely out of joint with all the theory of mining or of mine development. It is too ridiculous to merit discussion.

Section 7. Pertaining to lateral rights. I believe with Mr. Renaud, if not jumping out of the frying-pan into the fire, at least he would have one foot in the pan and the other in the fire.

In conclusion, I will say that I entirely agree with Mr. Renaud, and want to add my wish to his that all miners communicate with their Congressmen and Senators as soon as possible. Congress has always been sane on the mining question, and although we no longer have the venerable patriarch of the Senate from Nevada to champion the cause of our scattered forces, we have some of America's greatest citizens there, who are always ready to oppose wrong and fight for what is right.

GORDON D. STANLEY.

Azusa, California, August 30.

on an elaborate series of maps and sections. In later years, Reno H. Sales, who has been at the head of the company's geological department, has carried the work

forward and broadened its scope. In 1905 Mr. Brunton published a terse description of a system of geological maps and sections such as he caused to be elaborated for the Anaconda company.* In 1913 Frank A. Linforth, who is still a member of the company's geological staff, contributed an excellent description of the methods employed.† There seems little excuse for my writing on the subject except as a compliment to those responsible for this good work and for the opportunity of making some friendly comments, such as may serve the purpose of drawing the attention of the managers of mines in other districts to the usefulness of the Anaconda system.

First, it will be well to outline the local geology. This I can do best by referring to the scholarly paper on the 'Ore Deposits of Butte', by Reno H. Sales, presented at the Montana meeting of the Institute in August 1913.‡ The country-rock of the Butte mines is granite, or, more technically, quartz-monzonite. It forms part of a funda-

FIG. 1

mental mass called the Boulder batholith, which, as a magma, rose through the sedimentary rocks at the close of the period associated with the great crustal movement that formed the Rocky Mountains, late in Cretaceous time. The granite is penetrated by dikes and tongues of aplite, which represents a differentiation from the granite when it cooled and cracked. Next came another intrusion of igneous rock in the form of nearly parallel dikes of quartz-porphry that extended in an east-west direction across what is now the Butte mining area. Much later came an intrusion of rhyolite, in two bodies, one of which forms the Big Butte, the conical hill so prominent in the local topography. From these intrusive masses of rhyolite there extend dikes running north and south, across the copper veins, which apparently were formed before the rhyolite and after the quartz-porphry, which follows the course of the earliest veins.

The granite, aplite, and quartz-porphry are traversed by systems of fissuring, producing the dislocations called 'faults'. Ore has been deposited in some of the fissures;

others are barren and play the unpleasant part, from the miner's point of view, of disturbing the continuity of the orebodies. Six systems of fissuring have been recognized; of these the oldest is the one constituting the Anaconda copper veins, which strike east and west, and dip steeply, usually south. Next, in point of time, comes the Blue system of veins. These also dip steeply, sometimes north, sometimes south; they have a general course northwest-southeast, and therefore cross and displace the east-west fissures of the Anaconda system. Both are crossed and dislocated by a series of breccia faults, that is, fault-fissures filled with angular fragments of rock that have been torn from the walls of the cleft. This breccia resembles concrete. The breccia faults have a general strike of N. 75° E. and dip 65° to the south. They range in width from six inches to 30 ft. Next come the Steward fissures; these displace both the Anaconda and Blue veins, as well as the breccia-faults. The horizontal displacement they cause ranges from 50 to 150 ft. The biggest fault is the Rarus, first recognized in the mine of that name. Its general strike is N. 50° E. and it dips uniformly 45° to the north-west. In places it is 250 ft. wide, of crushed rock. In the Rarus mine it causes a horizontal displacement of 240 ft. It carries no ore except such as it has torn from the veins that it crosses. The sixth system, known as the Middle fault, is the latest in point of time, and therefore displaces all the preceding, as much as 75 ft. It has a strike N. 65° E. and dips south.

Obviously these systems of veining and faulting, with different strikes and dips, produce a complex of fissures and dislocations that renders it difficult for the miner to follow the ore. Indeed, without geologic study and careful mapping, the underground structure would be a maze defying economical exploration. To assist those responsible for the supervision of the mining operations it has been found necessary to make detailed surveys, and to record not only the position of the workings but also the nature of the wall-rocks and fissures observed in the levels and cross-cuts. Thus the navigator underground is given a chart wherewith he may steer his course and so follow or find the ore that is the object of his search in the darkness of the underworld.

At first it was difficult to make the foremen, and even some of the superintendents, realize the usefulness of geologic data in their daily work, particularly of searching for new orebodies and correlating the faulted portions of the known orebodies. One can rarely go 500 ft. without encountering some kind of break or fault. In parts of the workings the displacements may be repeated at intervals of ten feet and in different directions, so that any rule-of-thumb method fails and the foreman is at a loss. The help given to him by the geologist may be summarized as follows:

(1) He need not waste money in cross-cutting where a drift on a vein reaches a fault. The usual and un-instructed method is to continue the drift while thinking what to do. Now the geologist has authority to tell the foreman what to do, that is, which way to cross-cut for

*Trans. A. I. M. E., Vol. XXXVI, pp. 508-540.

†Trans. A. I. M. E., Vol. XLVI, pp. 110-122. Also 'Some Features of the Geological Department of the Anaconda Copper Mining Company', by Paul Billingsley, 'M. & S. P.', June 19, 1920.

‡Trans. A. I. M. E., Vol. XLV, pp. 3-106.

the other part of the vein, which means the probable extension of the ore. The foreman is instructed by the superintendent to follow the advice of the geologist, as represented by a member of that department. For example, in Fig. 1, a foreman might continue the drift *AB* through the fault to *C*. The geologist, after study of the dips and strikes of the intersecting vein and fault, and other structural details, would determine the probable position of the faulted segment of *AB* beyond the fault, and thereupon would instruct the foreman to turn his drift as indicated by the dotted lines from *B* to *H*, the object being to reach the vein beyond the fault with the shortest length of cross-cut consistent with convenience in mining.

(2) It used to be the custom to run short cross-cuts into the walls, to obtain waste for filling. Although this

ground, that is, rock so broken as to endanger the subsequent maintenance of the shaft or possibly the actual sinking of it. Similarly the geologist is able to select a place for the drill-hole through which an electric wire will be extended in order to save the shaft from the danger of fire due to a break in the insulation. Such a drill-hole, of course, must be made in ground that will not shift.

(5) The main purpose of geologic study is to aid in the search for ore. That, of course, represents the direct winning of money, whereas the other aids he gives the miner represents savings, the cumulative value of which runs into a sum comparable with that of a large orebody. The exploration of new ground is based upon careful and detailed study of the maps and sections, and the comparing of ideas between members of the geological staff.

FIG. 2. A RECOMMENDATION SHEET

was a cheap method of filling the stopes, the general effect in the mine was not good because it tended to check prospecting and development work on the levels. It is now the duty of the geologist to select the points where cross-cuts and drifts will serve to explore the ground as well as yield waste for the fill.

(3) In the general scheme of mine development, the geologist selects the points for starting prospecting cross-cuts or other work that may serve incidentally as a means of exploration. It is natural for a foreman to select the 'convenient' place for such a cross-cut, having regard to the economical tramming of the waste, rather than the place geologically most attractive.

(4) When a new shaft is to be started, the geologist selects suitable ground. This he can do by reason of his knowledge of the distribution of the various fissures and faults, thereby preventing the sinking of a shaft in bad

Thirty years ago it was unusual for a mining company to retain a geologist, who was called into consultation only when serious trouble developed, more particularly in the event of a general impoverishment of the mine. The manager or the surveyor was expected to decipher the vagaries of the structural geology, and sometimes he did, but usually a specialist had to be called upon, and only too often he came after much of the evidence necessary for a correct diagnosis had been obscured or obliterated, as the result of mining or caving. It seems a far cry from those hit-or-miss methods of the past to such a system as has been established by the Anaconda company: its success is due in large part to the fact that the decisions for new work underground are not made until the evidence has been discussed by the members of the geological department. A decision is not always the judgment of one man, it may represent the result of a

scientific consultation between several competent geologists.

(6) Last comes the aid given by the geologist in litigation, meaning the lawsuits arising from conflicting interpretations of the mining law, under the provisions of which extra-lateral rights are claimed by neighboring owners to the ore in veins supposed to have their apex in the claims or locations of the opposing parties. The geologist finds it interesting to procure and prepare data for the lawyers. The effort made in a court of law to determine the facts in an apex suit is unscientific because in the last resort the decision rests with a judge or a jury unversed in geology and restricted or impeded by a law inconsistent with the facts of nature.

The educative value, to the community, of such a geological department as that of the Anaconda company is unmistakable. The foremen in the mines were slow to appreciate the usefulness of geology; this was true more particularly of the old-timers, who mined the rich veins, and did not need to be told where to find ore. Moreover, in the early days of the Butte district the miner was not troubled much by faults; these became a serious obstacle only when the workings became deep. How far down the scale of employment the appreciation of geology goes, it is difficult to say. The miners themselves know that their work is guided by the geologists, and so develop an interest in the rock-structure. Directions or orders, of course, are given by the geologists not to the miners but to the foremen; but the miners hear them and that awakens their intelligent curiosity, which is the beginning of scientific study. For a long time the geologist was supposed to be not 'practical', and even to this day there are mining companies that refuse to believe that a geologist can help them. The geologist used to be called a 'theorist', largely because most people do not know what a 'theory' is, but, as a matter of fact, the miner himself, especially the prospector, is full of 'theories', if by them is meant unsubstantial surmises as to the nature and distribution of ore deposits. At Butte the miners see the exploratory work changed by the geologist from day to day in this or that direction, and with such changes they associate the subsequent finding of ore. This must impress them. Some of them at least must realize the difficulty of carrying a mental picture in three dimensions, especially in a mine traversed by many faults, involving big dislocations both vertically and horizontally, and complicated by movement in different directions, where fracture-planes of various dips and strikes intersect each other.

To understand these structural complexities and to interpret them intelligently, it becomes necessary to make accurate maps. These are of various kinds and are drawn to different scales.

(1) Geologic data are recorded on cross-sectional paper in loose-leaf notebooks.

(2) These are transferred to a set of maps on a scale of 50 ft. to the inch. They constitute the permanent official record and on them are recorded all the essential data.

(3) A set of maps on a scale of 100 ft. to the inch is made, to cover a larger area and therewith to co-ordinate the information obtained in the members of a group of mines. Each geologist is given a specified territory and his work is co-ordinated with that of the other geologists.

(4) For small incidental underground problems of a complicated character it is customary to prepare maps on a large scale, say, 20 ft. to the inch.

(5) An entire district is mapped on a 200-ft. scale for the purpose of a comprehensive correlation, giving a bird's-eye view of the geology of the district as a whole, and assisting mental vision at a wide angle.

(6) Glass models are made, to solve local problems. These models are of the kind used in apex suits. Once, however, a man has obtained a good mental picture of a rock structure, he does not need a glass model, which then serves as a means of explaining the geologic conditions to the officers of the company.

(7) In addition to plans, it is necessary to make an elaborate series of cross-sections, usually on a scale of 100 ft. and at intervals of 100 ft. apart, but occasionally in two directions in order to cover both the east-west and the northwest-southeast vein-systems.

(8) To aid those in charge underground it is customary to furnish the assistant general manager and the general superintendent with a complete set of geological maps drawn on a 100-ft. scale. The two assistant superintendents likewise are given sets of maps covering the mines in their charge. The foreman of each mine is given a geological map relating to his mine. The scale of this map will depend upon the size of the area under his supervision.

The general policy of mine development is left to the general superintendent, of course. The amount of such work to be done depends upon the condition of the mine, as to which the superintendent is the proper judge. It is part of the duty of the geological department to provide the superintendent with a list of places inviting exploration. This is done by means of 'recommendation sheets,' one of which is photographed in Fig. 2. If the general superintendent considers that the foreman should do more exploratory work, the latter consults these 'sheets' or goes direct to the geological department for fresh hints. If the foreman is of the opinion that he can do work most conveniently on a particular level, he will turn to his 'recommendation sheets' and ascertain if a place on that level is mentioned; if not, he calls upon the geologists for advice as to the place where he ought to start the work—a place fitting his arrangements underground and one likely to be the most promising for the finding of ore. In general, the foreman is not supposed to start any new work without previous consultation with the geological department, because any work necessary for convenience in mining may be combined with an opportunity for useful exploration.

A definite scheme of coloring is established, as might be supposed. Veins are marked in red, and faults in blue; but where faults are mineralized they are also marked with red. The aplite dikes are marked in green,

so is the Rarus fault; the quartz-porphyry is recorded in yellow. Dotting with small v's show that granite has been recognized. Dips are recorded at irregular intervals wherever a change of dip is significant.

The geology of each stope-floor is mapped and recorded in a set of books accurately oriented. A glass-top table, illumined from below by electric light, is used for making tracings. Sets of maps are kept in steel cases. Tracings of the 200-ft. map are hung on a wooden strip that slips into a groove along the top of the case, so that they hang vertically, can be removed readily, and occupy the least space. As 50 miles of mine-workings are made each year, it is evident that these records are voluminous.

If any further proof of the effectiveness of the geological work be needed, it can be obtained by examining a map and observing with what success the workings follow a multi-faulted vein. It remains to add that the present general superintendent, C. L. Berrien, served with the geological department for five years and obtained a training that has stood him in good stead in the even more responsible duties of his higher appointment. Stopping operations have reached a depth of 3400 ft. in the Original mine, but the deepest level is at 3800 ft. in the West Steward, where 10 ft. of 4% ore was cut recently. At Butte 3% of copper constitutes 'ore' nowadays. The deepest working is 3900 ft. below the surface, this being the depth of both the Original and the West Steward shafts.

Sulphur Industry of Sicily

Until recent years Sicily was an important source of sulphur, but it has now been displaced by America, which has developed a large production owing to the easy extraction from the Louisiana and Texas mines, states a consular report. The production of sulphur in Sicily rose from 120,000 tons in 1860 to 538,534 tons in 1905. In 1919 production decreased to 181,374 tons, but rose to 219,844 tons in 1920. On the other hand, the production of American sulphur increased from 893 long tons in 1883 to 25,000 tons in 1903 and 491,080 tons in 1913, and reached 1,255,249 long tons in 1920. Japan, with an output of about 50,000 tons, is the only other important source of sulphur.

The gradual decline of the Sicilian sulphur industry during recent years is shown clearly by the statistics of production, stocks on hand, and export of sulphur from 1898 to 1920:

Years	Production Metric tons	Stocks on hand Metric tons	Exports Metric tons
1898	465,021	235,022	460,800
1900	516,789	242,438	574,460
1902	501,021	329,836	481,280
1904	499,322	370,606	490,090
1906	475,553	537,588	399,100
1908	404,207	616,419	377,610
1910	397,808	641,249	395,944
1912	356,555	450,917	447,590
1914	334,974	369,001	338,308
1916	233,835	155,372	396,035
1918	194,585	112,050	230,769
1920	219,844	147,886	190,175

From 1860 to 1876 the price of sulphur averaged 140 lire (\$27) per metric ton. The return was so remuner-

ative that it encouraged exploration and production, with the result that the price diminished gradually between 1876 and 1895, when it reached the low figure of 55 lire (\$10.62) per ton.

To relieve the result of an attempt to corner the market in 1896, a company was organized at London, with a paid-up capital of 20,000,000 lire (\$3,860,000), called the Anglo-Sicilian Sulphur Co., for the purpose of controlling the production of sulphur in Sicily, purchasing the product, and re-selling it at a reasonable profit. This arrangement lasted until 1906, when the company was dissolved. Its operation had not met with success, because only about 60% of the mine-owners joined the syndicate, which was therefore unable to control the sales. American competition began to make itself felt; a large reserve stock had accumulated, the disposal of which was a problem.

This prompted the Government to take a hand. A compulsory consortium, or syndicate, was formed on August 1, 1906, in which all producers had to combine for a period of 12 years. The consortium was to fix the price of sulphur periodically, and when necessary to limit the production. It was to be operated by a director-general with an administrative council. Upon its expiration the life of the consortium was extended for another 18 years. The company came to a private agreement with a company in the United States as to the division of foreign fields for the marketing of sulphur. This arrangement was continued in the early years of the consortium, after which it was abruptly terminated, and American sulphur began to enter the European market; Rotterdam, Hamburg, and Antwerp became centres of distribution for the product in northern Europe, and Marseilles in the Mediterranean. In the latter a large plant was erected for the preparation of refined, ground, and other varieties to compete with similar Sicilian products.

Sulphur, which was required during the War for the production of ammunition, was in great demand; but, owing to the lack of ships, the delivery of American sulphur to Europe was interrupted. The Italian government commandeered the sulphur, authorizing exportation only with special permits. Now that freights are again normal, American sulphur exporters are everywhere underbidding the Sicilian product. In fact, the quotation for American sulphur c. i. f. Hamburg, was, at the beginning of June 1921, 1320 marks, whereas the Sicilian product was quoted at about 3000 marks. The latter has been completely displaced in the Scandinavian markets, and is facing keen competition in Belgium, England, the Netherlands, France, Germany, and Africa.

It is said that American sulphur is superior to Sicilian for the chemical industries. However, the latter is preferred locally for the vineyards, where it is used to protect the foliage against parasites, because it is said that the product from the United States does not adhere to the leaf to the same extent as does the Sicilian. Partly for this reason and partly because of their geographic location France, Spain, Portugal, Algeria, and Greece still look to Sicily for sulphur to be used in the vineyards.

Fusion Welding

By A. S. Kinsey

*No modern mechanical process possesses more encouraging possibilities than the welding of metals by fusion. The welded joint is not of modern conception, and the forge weld undoubtedly dates back to the earliest working of metals. However, the other kinds of welds have been in use less than 20 years. All welding is done either by plasticity or by fusion. The forge, the electric resistance, and the thermit-compression welds depend upon plasticity; the electric-arc, the thermit-cast, and the oxy-acetylene welds employ fusion. The respective merits of these two methods of making welds are rapidly becoming understood. Welding by plasticity has accomplished much. We have but to consider the manufacture of ordinary wrought-iron and steel pipe to appreciate the value of the forge weld. The speed and non-oxidizing features of the electric-resistance weld also have proved to the greatest advantage, as in the making of steel chain, for example.

But the plastic weld is limited in its application and is confined almost entirely to mild steel. The fusion weld, however, has a broader range of usefulness among the metals. Especially is this true of the oxy-acetylene weld, which is applicable to mild steel, tool-steel, high-speed steel, the new alloy-steels, cast-iron, wrought-iron, aluminum, copper, brass, bronze, lead, tin, zinc, in fact all of the commercial metals.

The possibilities of a good fusion weld depend on high tensile strength, ductility, density, control of the welders, and a proper method of testing welds.

TENSILE STRENGTH. The tensile efficiency of a weld is proportional to its thickness. This efficiency is of first importance, but it must not be obtained at the expense of ductility, that is, the bending and stretching qualities of the metal. In the welding of steel, for example, the ductility is of much importance. Again, to secure the proper tensile efficiency the welded metal must be thoroughly fused to the sides of the V of the base-metal. One of the best ways of securing a high tensile efficiency with mild steel is to use a nickel-steel welding-rod having a tensile strength nearly double that of the original metal. The result is likely to be a weld of higher tensile strength than that of the mild steel. The reinforcing of a weld is common practice.

DUCTILITY. The ductility of a fusion weld, particularly of steel, must be considered, although some would argue that a weld does not need to have bending qualities. One of the best illustrations of the value of ductility in a steel weld is to be found in the manufacture of welded-steel tubing, which can be made cheaper than the seamless drawn tubing. In order to obtain small-size tubing, the practice is to weld the steel in diameters of from 1 to 2 in. and then cold draw these tubes to the smaller sizes desired, some of them being as low as 5/32

in. outside diameter with 1/12-in. hole. It is to be noted that this tubing has an oxy-acetylene fusion weld along its full length, which must be capable of withstanding the strain of repeated cold drawing as the large tube is reduced to the smallest diameter. The weld not only withstands this treatment, but is found to be ductile enough successfully to stand being flattened, crushed, knurled, or bent. The welding of the larger-size tube is done, at the rate of from 3 to 5 ft. per minute, with multiple tips in an automatic machine.

POROSITY. One trouble with welds has been the lack of homogeneity of the welded metal, and usually the trouble is due to oxides. This applies to all methods of welding, but probably less trouble is experienced with the oxy-acetylene weld. In most cases the weld must be absolutely non-porous, and the density of its metal should be equal to that of the original metal.

CONTROL OF WELDERS. There must be a better control of welders; we must know exactly what these men are doing. Much attention is being given to this problem at the present time by the American Welding Society. One plan discussed is to require the shop foreman employing welders to have a thorough knowledge of the possibilities of the art, so that he may be capable of inspecting the work of the welders from time to time. The welders themselves should be trained thoroughly to understand the principles of their work, by giving them, say, an evening course in the practical metallurgy of the subject. With these precautions, and assuming them to be of average intelligence and dependability, the danger of poor welds should be greatly diminished.

TESTING OF WELDS. A number of ideas have been suggested for the testing of welds. Some shops require their welders to make sample welds each month which are tested; the results are posted on a blackboard for all the shopmen to read. Another plan is to cut out a section of a weld, where practicable, and examine it for fusion and porosity. If the welder does not know just when his work is to be tested, he is likely to be careful. We know of some cases where welders are being required, after making a good-sized weld, to stamp their initials and the date alongside so that there can be no question as to responsibility if the weld fails.

The fusion weld was first used in the repair shop. During the past five years, however, it has been gradually expanding to the manufacturing plant, where now it is of the greatest value. There was a time when nearly all steel tanks were riveted. Now many of them are being made with all welded joints. The locomotive fire-box is now being welded. Intricate castings, formerly impossible to make, are now cast in parts and the parts welded together.

Success has been obtained in the experimental welding of steels containing nickel, chromium, tungsten, cobalt, and vanadium. The depositing of alloyed steel on cheaper base-metals, where intense heat and wear are concerned, has been successfully accomplished by the oxy-acetylene torch.

*Abstracted from an address delivered to the Cleveland Section of the American Welding Society.

LA LLAVE SMELTER AT ZIMAPAN

Smelting Practice in the Zimapan District, Mexico

By Robert B. Brinsmade

INTRODUCTION. The first smelting operations in the Zimapan district of Hidalgo, Mexico, began in 1632, to treat the silver-lead ores of the Lomo del Toro outcrop. Judging from the huge piles of slag—estimated at 1,000,000 tons—that mark the seat of the ancient plants, it seems evident that operations must have been continued with regularity since then and at an average rate of 20 to 30 tons daily. It has always been the practice to re-treat the old slag as a help in the smelting of the ore itself.

At present Zimapan contains one copper plant, La Equitativa, and five lead plants, La Llave, San José, La Purísima, San Antonio, and San Nicolás, of which only the first three have been operated during the Revolution. Besides this there are several abandoned lead plants such as the Monserat, La Soledad, El Loreto, El Carmen, and La Cruz.

LA EQUITATIVA. This plant is owned by the Hidalgo Copper Mining & Smelting Co., which is controlled by Ludlow Bros. of Pachuca. It possesses two duplicate water-jacketed blast-furnaces which are operated, usually, in alternation, for copper matte. Occasionally one may produce copper matte and the other work-lead, as the change from copper to lead smelting is easily effected by digging out the crucible and decreasing the smelting column from 12 to 10 ft., with a corresponding lowering of the blast-pressure and an increase in the lead of the charge.

The blast-furnace is an excellent example of the type adapted for small operations, to be carried on at a long

distance from a railway and repair-shops. It is of round type with a diameter of 3 ft. 3 in. inside the tuyeres and 4 ft. 6 in. inside the stack. The latter, like the crucible, is built of segmental blocks, cut from local rhyolite, and consists of two layers, of which the inner is 6 in. thick and the outer 12 in. The stack is supported on steel box-girders, which rest on four posts of 6-in. iron pipe, and is capped on the feed-floor by a sheet-iron stack (shown, in the illustration, next to the elevator) with one door for charging. There are 8 water-jackets, of which the six at the sides contain holes for 3-in. tuyeres; the front jacket contains the slag-tap, and the rear jacket is blank. Originally these jackets were of rectangular section and of flange steel; but when worn out they were replaced by jackets made of 12-in. iron pipe flattened to an inside thickness of three inches, closed at the ends with plate-iron, dovetailed to the pipe, and caulked tight with Smooth-On cement. The jacket interstices are luted with clay. The crucible is of cylindrical shape, with a tubular tap for the exit of lead and matte together, when smelting for lead.

The air is supplied at 12-oz. pressure by a No. 4 Wilbraham-Green cycloidal blower, turned by a 10 by 15-in. horizontal slide-valve engine, which is fed by a 25-hp. return-tubular boiler. As blowing one furnace requires only seven or eight horse-powers, the engine can also turn the small dynamo that lights the plant at night. The air reaches the furnace through a 14-in. sheet-iron bustle-pipe, which is joined to each tuyere by a 7-in. nozzle and canvas tube. The tuyere consists of a 3-in.

iron tee whose front and top holes contain 3-in. nipples to connect with the water-jacket and the canvas air-tube, respectively; its rear hole is fitted with a 3 by 1.5-in. bushing and a $\frac{1}{8}$ -in. plug for a peep-hole.

The principal ore supply for copper smelting now comes from the Concordia mine in the Monte district, and is bedded in two beds of 130 to 150 tons each, which are fed alternately. The oxides of the upper stopes of the mine are mixed with the sulphides from the sump to produce a bed that contains:

	%	
Copper	1 to	2
Lead	4 "	5
Iron oxide	8 "	12
Alumina	10 "	15
Silica	32 "	38
Lime	1 "	3
Silver	600 "	1000 gm.

Besides this, some ore is used from the Purisima mine in the Balecones district; this is a mixture of iron and copper pyrites and contains 4 to 6% copper and 700 grammes or more of silver per ton.

The daily feed to the furnace consists of

	Tons
Ore	10.0
Limestone, 17% of charge.....	2.9
Custom slag	3.0
Foul slag and speiss	1.1
Total	17.0

For this is required 12% of coke, or two tons, and in case charcoal partly replaces the coke it is reckoned to require twice the weight for the same duty.

Each ingredient of the charge is placed in small iron buckets, and raised from the yard to the feed-floor by an elevator of 300-kg. capacity, operated by a hand-windlass and consisting of two counter-balanced cages. The custom slag is really a low-grade matte, which is picked from the ancient dumps of the city, and assays 2 to 3% copper and 400 grammes of silver, while the 'foul' slag re-treated from the furnace itself assays only 1% in copper.

The slag is tapped every five to ten minutes into cast-iron pots, holding 135 kg., which are wheeled to the dump on a truck and there left to cool on their tripod base. When cold, the matte is broken off the bottom of the slag cone for shipment, and the shell of foul slag returned to the furnace. The waste slag runs 35% silica, 30% iron oxide and alumina, 16% lime, and 0.2% copper. While the matte runs 8 to 10% copper and 3 to 5 kg. silver per ton. Thus the concentration is 5:1 on a charge going 1.6 to 2.0% copper and 600 to 1000 grammes silver. Owing to the presence of arsenic and antimony in the charge, there is always a little speiss produced; this is broken off from the matte and returned to the furnace for de-silverization along with the foul slag.

The laborers work in 12-hr. shifts, and their wages vary from P1 per day for the unskilled to P1.50 for the tapper. The blast-furnace occupies 10 men per shift, distributed thus: one tapper, one helper, two slag-wheel-

ers, one engineer and fireman, two elevators, two feeders, and one fuel-wheeler.

LA LEAVE. This plant is owned by the Cia. Minera de Zimapan, and up to 1913 ran mostly on custom ores; but during the Revolution the company acquired many mines, from which 80% of the present ore supply is drawn. The process used involves blast-furnace smelting, a stall-roasting of the matte, and a refining of the work-lead for the production of litharge and silver bars for the local market.

BLAST-FURNACES. There are two rectangular and one round water-jacketed furnaces. The round furnace has eight jackets, made of flattened 12-in. pipe as already described, with a slag spout in front and a siphon tap behind, and it was formerly run continuously in alternation with a duplicate furnace. The present practice, however, is to run only one of the big rectangular furnaces, intermittently—the ore supply is insufficient to do otherwise—leaving the other rectangular and the round furnace in reserve. Each rectangular furnace is 36 by 72 in. at the tuyeres, with one steel jacket at each side (containing four 3.5-in. tuyeres) and one at each end. The rectangular shaft above the jackets is 4 by 6 ft. in its interior section, and is lined with fire-brick that rests on steel box-girders supported by a cast-iron post at each corner. The smelting-column is held at 12 ft. above the tuyeres except in case of an excess of fines. The blast is supplied at 12-oz. pressure by one Wilbraham-Green cycloidal blower, with a No. 1 Root blower in reserve, each belted to a Vim horizontal engine of 20 hp. Steam is supplied by a return tubular-boiler, which consumes 2 tons of local wood daily when blowing one of these 50-ton furnaces.

Unlike the copper-furnaces, these blast-furnaces are set on a side-hill bench, and consequently the storage-bins are on a level with the feed-floor; the ore needs no elevating before charging. The ores treated may be classified in two groups:

	Silver		Lead	
Lime	22 %		6 to	10 %
Iron oxide	6 to	8 %	18 "	20 %
Silica	8 "	14 %	22 "	24 %
Silver	800 "	2000 gm.	600 "	1000 gm.
Lead			12 "	20 %

And a typical charge of 500 kg., of which four may be fed per hour, is:

	Kg.
Ore	300
Limestone	40
Roasted matte	25
Foul and custom slag.....	75
Cupel slag	10
Charcoal and coke (11%).....	50
Total	500

This yields a slag assaying: FeO, 28%; CaO, 14 to 16%; Al₂O₃, 8 to 9%; Pb, 0.5 to 0.1%; and Ag, 30 to 35 grammes.

No speiss is accumulated from this furnace, the arsenic in the ore being volatilized in the furnace or during matte-roasting. The slag is tapped into small slag-pots.

and handled as already described. The matte is broken off the bottom of the cold-slag cones, and sent to the stalls; the work-lead is ladled out of the siphon tap into molds for cupelling. To operate the furnace requires, per 12-hr. turn: one tapper, one helper, two slag-men, one engineer, one boiler-man, and five feeders.

THE ROASTING-STALLS. These are built of brick or stone and comprise 17 stalls; of which three are 6 ft. wide by 9 ft. high by 7 ft. long and hold 16 tons; the remainder are 5.5 ft. wide by 6 ft. high by 7 ft. long, and hold 10 tons. In shape they are rectangular, with an arched roof, 12 in. thick, and are built in a row side by side, so as to avoid the use of buck-stays; they debouch into a brick flue in the rear, of 4 ft. width by 7 ft. height. This last flue, in turn, is cut at right angles in the centre by another flue, 160 ft. long, which is terminated by a brick smoke-stack 3.3 ft. square inside, by 40 ft. high, and is shown at the extreme right in the illustration.

To light a 10-ton kiln requires 400 kg. of wood; roasting is allowed to proceed for 10 or 11 days, so that the 18 to 20% of sulphur in the original matte is reduced to 8%. The copper in the primary matte is only 1.5 to 1.8%; but, by successive roasting and re-smelting, this is finally raised to 11%; it is then shipped for refining to Aguascalientes.

REFINERY. This comprises two round cupelling-furnaces built of stone, hooped with steel, and lined with fire-brick; the hearth, however, is formed of a mixture of ground quartz and slag. The charge of work-lead consists of 10 tons; it is fed gradually, and finished, for silver bars of 35-kg. each, once in 80 hr. The cupelling is attended to by three men on 12-hr. shifts; the litharge yielded is sold locally, and is mostly used for glazing the native earthenware. The dust-flue that takes the blast-furnace smoke is built of rubble stone-masonry with an arched roof, and is 6 ft. high by 4 ft. wide inside. It follows up a gentle slope to a stone chimney 6.5 ft. square inside, by 60 ft. high. The trapped dust is mixed with lime, made into bricks by hand, and dried in the sun for smelting.

The ore is brought in sacks to the plant, and is dumped into flat ore-bins, which are separated by stone walls and paved with cobble-stones. Every fifth sack or so is taken for a sample and this is dumped onto the pile nearby. Each sample-pile is reduced, by quartering and coning, to a sample for assay. The coke is also kept in roofless flat bins, but the charcoal is stored in bins with high stone walls and corrugated-iron roofs. The offices and warehouses are built of stone, with iron roofs; the furnace sheds have similar roofs, but merely wood frames.

SAN JOSÉ SILVER-LEAD SMELTER. The blast-furnace here is round, and of 33-in. inside diameter at the tuyeres, of which there are five of 3-in. diameter, one in each of the steel water-jackets. The siphon-tap has recently been taken out of the crucible, because it continually clogged from the chilling of speiss; only one of the arsenides of iron is easily fusible, the remainder being pasty at the ordinary furnace temperature. The lead and matte settle together in the crucible and, every

3 or 4 hr., are tapped out into a flat hole in the floor that is lined with clay. From this hole the work-lead can be ladled into iron molds, and is clean enough for direct cupelling; the scum of the hole is a mixture of matte and speiss, and is crushed for roasting. This furnace treats 15 tons of ore per day, which means a total charge of 25 tons. The work-lead output is at least 7% of the charge of ore and flux, and averages 8 to 10 kg. of silver, or about 1%. The furnace is blown by a 60-hp. Corliss engine, which was formerly used at the dismantled Monserat plant and is consequently much too large. However, by using only 50 lb. steam pressure and a minimum cut-off, the engine output is reduced to the 15 hp. or so needed for the No. 3 Root blower that supplies the blast-furnace with air.

A noteworthy feature of this plant is the sintering roaster devised by Aloys Preusser, the metallurgist and owner. Raw sulphide, matte, or speiss is first broken in a jaw-crusher, and then ground in a pair of 24 by 12-in. rolls to $\frac{1}{2}$ -in. diam. The sintering furnace consists of a steel stack of 26-in. diam. by 120 ft. high, around whose brick base are placed three fire-places, each surmounted by an iron grid, 7 ft. long by 3 ft. wide, and sloping outwardly at 4 to 1. These grids are made of cast-iron grate-bars, closely spaced; on them is spread a charge of crushed ore, 4 in. thick, and of such a composition, respecting lead and iron, as to sinter easily. The ore is lighted by igniting a cover made of dry magney leaves, or other refuse fuel, and continues to burn for 1 to 1½ hours, until the original content of sulphur of 15 to 20% has been reduced to 3 or 4%. In the day shift, of 12 hr., each of the three grates can put through eight charges of 400 kg., or a total of three tons. This method of sintering is a great improvement over the heap-roasting formerly in vogue for the same ore at the Baleones mine. The heaps were built to hold 200 tons of ore, and to reduce the sulphur content from 15 to 20 down to 6 to 8% might require two or three months. It was found advantageous to build these heaps on a porous floor, like a mine dump, so as to promote ventilation.

PURISIMA SILVER-LEAD SMELTER. This plant offers the best example of smelting in blast-furnace unprovided with water-jackets. There are twin round-furnaces of an inside diameter of 84 cm. at the tuyeres. The crucible and stack are built of local porphyry, cut of segmental shape in two layers, each about 9 in. thick, so the outside diameter is nearly 6 ft. The stone furnace is enclosed from tap to feed-floor by a sheet-iron shell; when the inner lining of stone is slagged out, which usually requires a month, the active furnace is blown-out for repairs, and the one held in reserve is blown-in. This furnace will handle about 10 tons of ore and flux daily, with a consumption of 12% of charcoal, and requires an 8-hp. steam-engine, which consumes only $\frac{1}{2}$ ton of wood per day. There is no siphon tap, but lead and matte are tapped every three hours from the crucible into a hole in the floor, and handled as described for the San José furnace. Air is supplied through three 3-in. tuyeres from a Root cycloidal blower. The ore of the

Ortiga camp charged here contains from 12 to 15% lead, and 600 to 800 grammes silver; only 25% of foul slag and some limestone and iron ore are needed to make a fusible slag. In 1919 the lead matte could be shipped to Aguascalientes when it assayed 8% of lead and 2 kg. of silver, but now it would hardly pay. The work-lead here contains 5 kg. of silver per ton, and is cupelled for marketable litharge and silver. The small quantity of speiss produced is used as a furnace 'medicine' to scour out accretions on the lining. For a small furnace like this the absence of water-jackets undoubtedly hinders freezing and saves fuel, but has the disadvantage of more frequent blow-outs in order to repair the lining.

SAN ANTONIO SILVER-LEAD SMELTER. This plant was re-built in the 'nineties, but was never blown-in because of an insufficient ore supply in the Lomo del Toro mine. The new blast-furnace was supplied by the Colorado Iron Works Co., and is 30 by 60 in. inside the tuyeres, of which there are three of 4-in. diameter on each side and one at each end, or eight in all. The water-jackets are of cast-iron, three on each side and two on each end, or ten in all. There is a slag tap at each end, and a siphon lead tap at each side of the crucible. The furnace is built against a hillside, so that the ore-bins are situated on the feed-floor, which is 15 ft. above the tuyeres. Power is furnished by a 30-hp. Erie return-tubular boiler, which supplies an Erie horizontal centre-crank engine belted to a Connorsville cycloidal blower. The cupelling furnace is built of stone, with a brick-and-stone chimney, and is distinguished by having an iron-bound removable brick roof, which places it within the German type of cupel.

TRANSPORTATION AT ZIMAPAN. One of the greatest handicaps to smelting operations has always been the distance from railway transportation; the heavy grades on the roads are such that the use of motor-trucks or caterpillar tractors is impracticable. Sayula, on the Nacional railway, is 45 miles; Ixmiquilpan, on the Honey railway from Pachuca, is 28 miles away. In fact, pack-animals are found cheaper and more convenient, for bringing smelter supplies, than carts. Coke arrives at Sayula direct from the Coahuila coalfields, and is brought by burros to Zimapan, who carry back litharge and matte, as return freight, from the La Llave smelter. The trip to Ixmiquilpan is hillier but shorter, so it is gradually displacing the Sayula route. The survey for the Honey railway from Ixmiquilpan to Zimapan was completed long ago; but, owing to the Revolution, its construction has been indefinitely suspended. Until Zimapan has direct railway connection, little can be done toward utilizing the large bodies of lead-zinc sulphides that have been developed in the Balcones mining camp.

Owing to scarcity of fodder at Zimapan, due to lack of rainfall and shortage of water for irrigation, the transport of ore from the mines, and of charcoal from the wooded mountains to the east, is costly. The freight on ore from Balcones camp is \$10 per ton, and is considerably more from either Monte or Ortiga; it is nearly half this sum from even the nearby camps of Arcabuz

and Poder de Dios. Charcoal is getting gradually scarcer, and its price, together with that of cordwood, is steadily rising, as they have to be garnered at greater distances. At present, charcoal varies in price, seasonally, from \$27.50 to \$33 per metric ton; wood is worth \$14 per cord.

OUTSIDE SMELTERS. The numerous small plants in the Zimapan district, outside the city, possess little beyond historical interest, as only one is at present in operation—the Barrera lead-silver works at Cardonal. This smelts in one of two small stone furnaces, which treat about 1.5 tons of ore daily, containing 20% lead, together with a nearly equal quantity of flux and ancient slag, using charcoal as fuel. The furnace is blown by a cycloidal blower, which also supplies the air for cupelling. The blower is turned by a 5-hp. engine, the steam being supplied by a wood-burning boiler.

AFTER the Armistice, zinc production was not begun in Belgium until May 1919; owing to the difficulty in securing coal and ores, the monthly production at the close of that year was less than 5000 tons, states a consular report. In 1920, conditions improved, and in May the production of raw zinc amounted to 7370 tons. The Belgian production in 1920 was 82,960 tons, in comparison with 19,860 tons in 1919 and 204,220 tons in 1913. At the close of 1920, Belgian producers began to curtail production, and the total yield of Belgian plants decreased to 6530 tons in February, 4640 tons in March, and 4320 tons in April 1921. Belgian manufacturers claim that, with the present prices of coal and labor, profitable production is impossible; zinc prices, which were 2300 francs per ton in January 1920 and 2850 f. in February, have now dropped to 1450 f. The Mines et Fonderies de Zinc de la Vieille Montagne produced, in 1920, 19,080 tons of raw zinc, and 70,000 tons of finished zinc products, in comparison with 130,000 tons of the latter annually before the War. The production of sulphuric acid for the past year by this plant was only 10,000 tons, as against the pre-war production of 100,000 tons per year. In general, however, the production of sulphuric acid in Belgium was unfavorable; approximately 400,000 tons of acid was produced in 1920. Besides the Vieille Montagne, there are in Belgium three other important zinc concerns—the Société Métallurgique de Corphalie, with a plant near Huy, which during the fiscal year 1919-'20 produced 3772 tons of raw zinc; the Compagnie des Métaux Overpelt Lommel, with plants in the northern part of the Province of Limburg, producing zinc, sulphuric acid, arsenic, and superphosphates; and the Société de la Nouvelle Montagne, producing at present about 10,000 tons of zinc products annually, including 5930 tons of raw zinc and 4438 tons of rolled zinc in 1920. This plant also produced 19,223 tons of sulphuric acid during the past year. Only two Belgian plants manufacture lithopone. They are the Société Anonyme des Produits Chimiques de Wilsela, near Louvain, and the Société Anonyme Stella, at Haren, north of Brussels.

The Magnetometer as an Aid in the Development of Mines

By Arthur Gibson

INTRODUCTION. The original Swedish mining compass, commonly called the dipping needle, invented more than 150 years ago, has been superseded by a sensitive type of instrument, known as the magnetometer. Magnetometric instruments for the determination of the earth's magnetic field were invented and developed in Sweden, and have been in use more than 40 years. Their application, so far, has been confined almost exclusively to iron-ore deposits, but I have obtained good results by the use of these instruments in both placer and hard-rock mining.

The design of the instruments has been improved greatly during the past 25 years, and it now proves a valuable aid to mining. Quoting Eugene Haanel's book 'On the Location and Examination of Magnetic Ore Deposits by Magnetometric Measurements': "In the hands of experts, furnished with such instruments, the Swedish methods yield data from which magnetic orebodies may be located, and in many cases their strike, direction of dip, and depth below the surface determined." Outside Sweden, such instruments have been used extensively in several of the European countries, in Canada, and at the iron mines in the Eastern and Middle States of the United States. The Swedish government had an exhibit of magnetometers in the Swedish building at the P. P. I. exposition; the University of California bought one of them for their mining department.

DESCRIPTION. Magnetometers are constructed to record either horizontal- or vertical-, or both horizontal- and vertical-magnetic intensities. The old method of reading the angle of variation, deviation, or deflection in the horizontal plane, and the angle of inclination or dip in the vertical plane of the magnetic needle, direct by degrees and fractions thereof, has been discarded, and a compensating or deflecting magnet has been introduced, whereby much closer and more accurate readings are obtained. The compensating magnet acts on the principle of like poles repelling and unlike poles attracting each other, thereby forcing the magnetic needle into certain positions when moved toward or away; the reading thus recorded is a measurement of the distance between the magnetic needle and the compensating magnet. The greater the magnetic intensity, or local attraction, the shorter the distance between the magnetic needle and the compensating magnet, and *vice versa*. One magnetometer, the Thomson-Thalén type, has the compensating magnet attached to a graduated stem that is operated by a micrometer screw, which is divided into 100 parts, each division representing a movement of the compensating magnet of three ten-thousandths (0.0003) part of an inch; this illus-

trates how much closer the readings are as obtained by magnetometers than by the old method of reading the angle direct.

MAGNETISM OF ORE DEPOSITS. Magnetic minerals can be classified into attractile magnetic minerals, and retractile magnetic minerals. Attractile magnetic minerals, such as magnetite and pyrrhotite, like tempered steel, retain their magnetism when once magnetized. Retractile magnetic minerals, such as hornblende and pyrite, like soft iron, become magnetic when attracted by a strong magnet, and lose their magnetism when removed from the magnet. Retractile magnetic minerals, in order to act as magnets, require a greater inductive force than that produced by the earth's magnetic field, and do not alone have any influence on a magnetic needle. When mixed with attractile magnetic minerals they become magnetic and exert a much greater influence on the magnetic needle. A deposit of magnetite and pyrite has a much stronger influence on a magnetic needle than a deposit of pure magnetite, other conditions being identical.

The magnetism of ore deposits may be due to the presence of attractile magnetic minerals, to the inductive effect of the earth's magnetic field, or to the inductive effect of electrolysis in the ore deposit. A mineral deposit containing two or more minerals, of which one is always more positive and one more negative than the other, electrically speaking, is frequently the centre of electro-chemical action that results from the penetration of surface water through fissures, crevices, or porous rocks, the water becoming alkaline or acid. This process is generally the cause of secondary enrichment, which rarely extends further than a depth of from 200 to 300 ft. below the surface.

These conditions are not alone confined to mineral deposits in hard rock or solid formation; they apply as well to some placer deposits. Gold has no attraction for, or effect on, the magnetic needle. Magnetometric indications of a mineral deposit or a concentration in a placer is due either to the presence of black iron sand, which generally follows the gold, or to two or more minerals. I have obtained good results by magnetometric surveys in placer deposits, and where there was no evidence of the presence of any magnetic (attractile) minerals.

MAGNETOMETRIC OBSERVATIONS AND DETERMINATIONS. Observations must be conducted by experts in order to obtain reliable results; this is particularly true in regard to calculations of the depth of orebodies. Magnetometric surveying is classified into horizontal and vertical measurements. The horizontal measurements are of minor im-

portance, but the vertical measurements furnish data from which valuable charts are platted, showing the extent and position of the ore.

A compass-needle that is influenced only by the earth's magnetic field is placed in what is termed the normal or neutral magnetic field, and a compass-needle that may be influenced by an ore deposit, or other local magnetic attraction, is placed in what is termed the disturbed magnetic field or, simply, the magnetic field. A compass-needle free to swing in the horizontal plane will place itself with its axis north and south, in the magnetic meridian. The magnetic meridian, with few exceptions, does not coincide with the true or astronomical meridian, the angle of deviation being termed the magnetic variation, or deflection. This magnetic variation is due to the influence exerted by the earth's magnetic field, and to other local magnetic attractions; it is either increasing or decreasing at an average rate of one to four minutes annually, depending on the locality. A compass-needle free to swing in the vertical plane, in the normal magnetic field, will place itself with its axis forming an angle with the horizontal plane; this angle is termed the angle of inclination, or dip, and is parallel to the magnetic lines of force for any certain locality. In the northern hemisphere, the north end of the needle dips when in the normal magnetic field; at the magnetic north pole, the needle will place itself perpendicular; at the magnetic equator it is horizontal.

The strength of the earth's magnetic force varies according to position upon the earth's surface. The total magnetic intensity of the earth at the north magnetic pole is equal to 0.64 centimetre-gramme-second; at the magnetic equator the average value is 0.32 c.g.s. The angle of inclination or dip in a disturbed field is generally greater than in the normal field for the same locality, but it may be less, or even reversed; in some instances the south end of the magnetic needle may dip on the northern hemisphere, which then is termed south polarity. North polarity is always considered positive, and is indicated on charts by a blue color; south polarity is always considered negative and is indicated on charts by a red color.

A magnetometric survey is conducted, first, by a preliminary investigation with a magnetometer, or dipping needle, to ascertain the approximate position and strike of an ore deposit; and, second, by dividing the surface into squares with sides of from 30 to 50 ft. that follow a base-line along or parallel to the general direction of the strike of the orebody. Magnetometric observations are taken at each intersection, with intermediate observations if necessary; from these the corresponding total vertical magnetic intensities of the orebody are calculated, and subsequently platted on charts. Calculations of the total horizontal and vertical-magnetic intensities of the earth's normal magnetic field, and of an orebody, are too exhaustive to be discussed. For a full and detailed account see Eugene Haanel's book (No. 4), listed at the end of this paper.

CHARTS OF VERTICAL MAGNETIC INTENSITIES. The total vertical-magnetic intensities are platted on cross-section

paper, and like or identical values are connected with contour lines, isoclinical or isodynamic lines, which show at a glance the location of the ore deposit.

The following rules must be observed closely in order to obtain accurate and reliable magnetic intensity charts: It is important to find the position for the maximum value of the vertical-magnetic intensity; for this purpose it may be necessary to take observations at 10- to 15-ft. intervals at and near the point of maximum magnetic intensity. Contour lines, showing elevations, should be platted on these charts wherever the surface is hilly or mountainous, otherwise serious errors may occur as to the true position and extent of the orebody. Objects such as houses, roads, rivers, lakes, telephone- and telegraph-lines, high-tension electric-lines, and railroads must be marked correctly on the charts for future reference. It is important to mark correctly the position of any and all dumps of magnetic rock on the surface, which generally show negative attraction along the sides, and positive attraction on top and underneath. The astronomical as well as the magnetic meridian, the latter in the earth's normal magnetic field, should be marked on the charts.

These vertical magnetic-intensity charts will indicate that the strike of the orebody is along the direction of the longest axis of the curve of maximum magnetic intensities; the dip of an orebody is indicated by the slow decrease in the vertical magnetic intensities in this direction; the most suitable location for a prospecting shaft is within the contour line representing the maximum vertical-magnetic intensities. The charts will show the extent of the mineral deposit or orebody.

The distance of the upper pole or apex of the orebody below the surface or plane of observation can be determined approximately. Several methods of calculation can be employed for this purpose. The depth of an orebody can in certain cases be determined approximately. Several methods of calculation are mentioned in Eugene Haanel's book, previously mentioned. The general rule is that the orebody has a considerable depth where the north-pole attraction shows a great width.

PROFILE CURVES. Profile curves of vertical-magnetic intensities along lines crossing an ore deposit at right angles to its strike are constructed by using distances between points of observations as abscissas, and values of vertical-magnetic intensities as ordinates. These curves show distinctly that where the vertical-magnetic intensity is at a maximum, the distance from the surface or plane of observation to the orebody is at a minimum. Where several orebodies occur in close proximity and more or less parallel to each other, the profile curves become complex, and it will be necessary to analyze them into their component curves.

CORRECTIONS TO BE MADE. Corrections must be made in order to obtain true and accurate values of the observations. Errors in this connection may be due to annual changes of the magnetic variation, diurnal changes of magnetic variation, temperature variations, which are the most important, and sudden variations, due to cosmic magnetic disturbances.

The annual changes of the magnetic variation are constant from year to year for both rate and direction, thus the corrections in this case are readily made. The diurnal changes of the magnetic variation are generally small, and are corrected ordinarily in conjunction with temperature corrections. Temperature variation in some climates differs considerably between morning, noon, and night; this affects the instrument as well as the magnetic needles. The errors caused by temperature variations in the direct-instrument readings may at times reach the most unexpected magnitude; and, for this reason, observers are cautioned not to overlook this matter. Sudden variations, due to cosmic magnetic disturbances, are, as a general rule, impossible to calculate or estimate; it is inadvisable to take observations during electric storms.

PRECAUTIONS TO BE OBSERVED. The observer should assure himself that he is carrying no magnetic bodies, such

instrument in a warm room until dry, with glass cover open if necessary. No observations should be taken during electric- or thunder-storms; magnetic readings are then more or less unreliable. Cloudy days are best for the taking of magnetic readings in the field. The instrument must be shaded from bright sunshine. Magnetometric instruments appear most sensitive at full moon.

THALEN-TIBERG MAGNETOMETER, PROVIDED WITH TANGENT AND SINUS ARMS, FOR READING HORIZONTAL INTENSITIES

THALEN-TIBERG MAGNETOMETER, PROVIDED WITH TANGENT ARM, FOR READING VERTICAL INTENSITIES

as pocket knives, keys, stick-pins, iron buttons, or hat wires on his person.

Magnetic bodies that occur in the field, and cannot be removed, such as magnetic-ore dumps or corrugated-iron buildings, must have their position accurately marked on the charts, so that the disturbing effect may be estimated. Bright sunshine, and the friction caused by wiping the glass cap of the compass-box, will electrify the glass, rendering the needle indications untrustworthy. By breathing upon the glass the electricity is discharged. The strength of a magnet decreases with increase in temperature; it recovers its original strength upon a return to normal temperature. Magnetic observations should not be made during rapid variations in temperature. The strength of a magnet decreases permanently as a result of concussion. The glass cover of the compass-box should be opened as seldom as possible, in order to avoid an accumulation of dust in the bearings, which reduces the sensitiveness of the magnetic needle. An accumulation of moisture on the needle during damp weather may impair its balance, and may cause defective readings when used as an inclinometer or dipping-needle. Moisture is best removed from both glass cover and needle by placing the

THOMSON-THALEN MAGNETOMETER, FOR READING VERTICAL INTENSITIES

The storing or carrying of magnetometric instruments in close proximity to direct-current generators or motors should be avoided. For instance, while riding on an electric street-car the magnetic needles may become demagnetized, or the poles may become reversed, thus rendering the magnetometer worthless for field use until re-magnetized and adjusted. The greater the sensitiveness of

the magnetometer, the more reliable the results. The observer must, therefore, be prepared to re-magnetize and adjust his magnetometers in the field in order to ensure accuracy.

FALSE CONCLUSIONS FROM MAGNETIC SURVEYS. Every attraction upon the magnetic needle extending over a large area does not indicate necessarily the presence of a mineral deposit of commercial value. Volcanic rocks and lava, more or less impregnated with magnetite, occur at numerous places, but they never contain magnetite in sufficient quantity to be classed as iron mines. These rocks attract the magnetic needle, generally over a large area, but do not show any definite or distinct area of maximum magnetic intensities. A series of observations taken at short intervals along a line crossing a deposit of this nature, at right angles to its general course or strike, shows a continuous variation of the vertical-magnetic intensity, in the same way as if a great number of separate and parallel orebodies did occur. A true orebody that attracts the magnetic needle, always shows one or more areas of maximum magnetic intensity.

Placer deposits containing black iron sand show light magnetic intensities along the course of the stream, with segregated sections of greater magnetic intensities that are due to a more intensified mineral concentration at 'drop-offs' or natural riffles in bedrock, and along the inside curves in bends or turns of the stream.

CONCLUSIONS. Magnetometric observations of vertical-magnetic intensities of ore deposits do not indicate any specific mineral or its value—these questions must be solved by actual prospecting and development work—but they indicate the sections that contain the greatest mineral concentration. Thus the battle is virtually half won when an engineer knows where to sink a shaft or where to commence development work, in order to reach an ore deposit with the least loss of time and with minimum expense.

It is true that some ore deposits have no effect on the magnetic needle, and cannot be traced or found by the aid of the magnetometer; but in most instances there are indications of weak vertical-magnetic intensities, if the magnetometer is properly sensitized and in perfect adjustment.

Magnetometric investigations are particularly valuable for ascertaining the position and extent of iron-ore deposits; also for picking-up the extensions of mineral deposits, in hard rock or solid formation, that have been displaced or faulted, or are covered and obliterated; in the exploration of placer deposits covered by lava, gravel, or other material, or in unknown narrow sinuous channels in wide valleys, where the cost of prospecting would otherwise be too great.

Magnetometric observations that indicate a mineral concentration in placer formation is no index of the presence of gold, but it does indicate that placer gold, if there, will be found where the mineral concentration is indicated; and this is where the miner or prospector should look for it.

In a paper read before the British Association, at Cardiff, H. M. Wells and J. E. Southcombe gave the reason why the fatty or fixed oils possess superior friction-reducing properties to that of mineral oils. They have shown that this is due essentially to the presence in fatty oils of minute quantities of free fatty acids, which are absent in the majority of mineral oils. In consequence of this discovery they have added small quantities (about 1%) of fatty or organic acids, which are easily accessible and relatively cheap, to mineral hydrocarbon oils. The products so obtained possess remarkably low frictional coefficients. As an example, the addition of 2% of common fatty acid to a mineral hydrocarbon oil reduces the coefficient of friction shown by this oil on a friction-testing machine from 0.0084 to 0.0052—a diminution of 26%. By choosing the type of fatty acid to be added to mineral oil, the behavior of oils in the presence of water and other contaminating substances can be modified at will. It is also shown that the risk of metallic corrosion is even less with these oils than with the usual compounded oils, because the latter frequently develops in working notable quantities of free acid.

GOLD may be electrolytically deposited, rapidly and quantitatively, from solutions of the chloride containing acetate, this method admitting of the separation of gold from copper, palladium, and platinum, according to W. H. Treadwell, in 'Helv. Chim. Acta'. The readiness with which palladium is attacked in comparison with platinum, when subjected to anodic polarisation in hydrochloric acid solution, serves as a means for the approximate estimation of the palladium content of a precipitate composed of a large proportion of palladium and little platinum.

Book Reviews

Mine Accounting and Cost Principles. By T. O. McGrath. 260 pp., ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price \$4.

The author, who is the auditor of the Shattuck-Arizona Copper Co., shows that the present tax laws of most of the States and of the Federal government require that accurate records be kept and that complete reports be made to the Government of the results of each year's business. The employees of large industrial units are demanding that they be informed of the results of their labor, and be given a share either of the profits of the business or in the savings resulting from their increased efficiency or effort. The general public is insisting that, because it is the consumer of all products, the costs and profits of industry shall be accurately determined and made public. The mining industry is operating on a narrow margin of profit; to protect against loss, the costs must be known from month to month. These preliminary remarks indicate the demand that is now being met by the publication of the book under review, which contains a complete presentation of the principles of accounting and costing of mining operations, with sufficient forms, charts, records, and procedure to illustrate how the principles are applied in actual practice. From it one can find how to determine the current expense, prepaid expense, and asset or capital charges, how to determine the current and accrued income by means of production accounts, sales and receipt accounts, and inventories, so as to conform to the requirements of the Treasury Department's regulations governing the making of income-tax returns. It will be found of considerable value to auditors, treasurers, comptrollers, and other directors and executives of mining companies. The contents of the book are as follows: Section I. Promotion, Development, and Equipment. Section II. Operating Production. Section III. Administrative Accounting. Section IV. Cost Accounting.

Elements of Specification Writing. By R. S. Kirby. vii + 153 pp., John Wiley & Sons, New York. For sale by the 'Mining and Scientific Press'. Price \$1.50.

This is the second edition of a treatise on the art of writing specifications and is the outgrowth of a series of lectures delivered before the senior class in civil and sanitary engineering in the Sheffield School of Yale University, in which institution the author is assistant professor. The following features are worthy of note: The fundamentals of a contract, particularly of a construction contract, with its attendant plans and specifications, are given. A chapter is devoted to the advertisement and one to the proposal. The general clauses are given detailed attention; many interesting cases are cited to illustrate their application to actual construction work. Practical suggestions are given that deal with the specific clauses. Outlines of such clauses for nine simple construction projects will assist the student as he endeavors to grasp the composition of specifications. A classified list of references will furnish the student and the instructor with much material for comment and illustration. The new edition contains much new material; the first two chapters have been re-written. The book will be found of value to all those who are interested in the subject.

Concrete Work, Vol. II. By W. K. Hatt and W. C. Voss. 206 pp., ill. J. Wiley & Sons, New York. For sale by the 'Mining and Scientific Press'. Price \$2.

This volume has been prepared to develop the practical ability of the concrete worker, the inspector, and the student in technical schools. As the author states in the preface, most of the applications of concrete are founded on a few

fundamental principles and operations: computing, selection of materials, mixing, and placing. Once these elementary principles are understood, subsequent applications in diverse construction may be made intelligently, and practices may be modified to suit new conditions. The book is meant to fill the gap between the theory of the engineer and the special technology of the contractor. The following subjects are treated: Section I. Drawing and Computing. Section II. Preliminary to Construction. Section III. Inspection, Proportioning, and Tests of Materials. Section IV. Forms. Section V. Mixing Concrete. Section VI. Reinforced Concrete Construction. Section VII. Sidewalk Construction. Section VIII. Products. Section IX. Walls.

Manhood of Humanity: The Science and Art of Human Engineering. By Alfred Korzybski. E. P. Dutton & Co., New York. 264 pp. Price, \$3.

As Count Korzybski states in the preface, this book is primarily a study of Man, and takes into consideration all the characteristics that make Man what he is. An effort has been made to approach the problem from the mathematical as well as from the scientific point of view. It is obvious that, in order to be able to speak about the great affairs of Man—his spiritual, moral, physical, economic, social, or political status—it must first be ascertained what Man is. Although care has been taken to avoid vague terms, and although the book may seem critical of things metaphysical, it has been written with a desire to find the source of the qualities of mind, soul, and spirit, to measure their scientific significance, and to adduce scientific proof. By doing so, they may be studied without the digressions and misinterpretations that are caused by the personal emotions. The contents of the book are as follows: I. Introduction: Methods and Processes of Approach to a New Concept of Life. II. Childhood of Humanity. III. Classes of Life. IV. What is Man. V. Wealth. VI. The Capitalistic Era. VII. The Survival of the Fittest. VIII. Elements of Power. IX. Manhood of Humanity. X. Conclusion. There are three appendices, on (1) Mathematics and Time-Building; (2) Biology and Time-Building; and (3) Engineering and Time-Building.

Aircraft Handbook. By Fred H. Colvin and Henry F. Colvin. Pp. 415, illus. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

The first edition of this book was compiled under the stress of war conditions; it was not a complete study of the question but, nevertheless, it was used extensively, both at home and abroad. The development of aircraft during and since the War has necessitated a thorough revision. Aviation today is much more a matter of science and certainty than before. The increasing use of instruments, both for navigation and for the information of the pilot has involved the addition of a new section. International air laws are in force; extracts are given. A large amount of technical detail is included. The contents are as follows: 1. Simple Airplane Theory. 2. General Construction. 3. Woods for Airplane Construction. 4. Propeller. 5. Rigging the Plane. 6. Notes and Instructions to Government Inspectors of Airplanes and Airplane Engines. 7. Airplane Engine. 8. Characteristic American Airplanes. 9. Assembling the Curtiss JN4. 10. Liberty Motor. 11. Table of Characteristics of American Airplane Engines. 12. Curtiss OX Engine. 13. Curtiss C6 and C12 Engines. 14. Hall-Scott Airplane Engines. 15. Wright-Hispano Engine. 16. Gnome Airplane Engine. 17. Instruments. 18. Extracts from International Air Laws. 19. Landing Fields. 20. Military Equipment. 21. Airplane Standards. 22. Trouble Shooting for Airplane Engines. 23. Tables and Diagrams. 24. Nomenclature.

Elements of Engineering Geology. By H. Ries and Thomas L. Watson. John Wiley & Sons, Inc., New York. 5½ by 8½, 365 pp., ill. For sale by 'Mining and Scientific Press'. Price, \$3.75.

This book emphasizes the practical application of the problems of a geologic character that confronts the engineer in almost every branch of his profession. It is more than a condensation of the author's larger text, 'Engineering Geology'; it is the result of the complete re-writing of many parts of the larger book and the amplification of other parts. Those who may require a smaller volume to meet the requirements of a briefer course will find this a reliable textbook. The contents are as follows: The Important Rock-Making Minerals. Rocks and their Relations to Engineering Work. Structural Features and Metamorphism. Rock-Weathering and Soils. Development Work and Control of Rivers. Underground Water. Land-Slides, Land Subsidence, and their Effects. Relations of Wave Action and Shore Currents to Coasts and Harbors. Origin and Relation of Lakes and Swamps to Engineering Work. Origin, Structures, and Economic Importance of Glacial Deposits. Road Foundations and Materials. Ore Deposits. Appendix A: Geologic Column.

American Sulphuric Acid Practice. By P. DeWolf and E. L. Larison, with a chapter by W. M. LeClear. McGraw-Hill Book Co., Inc., New York. 270 pp., ill. For sale by the 'Mining and Scientific Press'. Price, \$3.50.

As stated in the preface, the writers' purpose in preparing this volume has been to provide fundamental information for the man with little preliminary knowledge of the subject. It does not pretend to cover acid manufacture with the thoroughness of Lunge. Sullivan's 'Handbook' deals with the laboratory end so satisfactorily that his methods are recommended by the authors, and laboratory practice is not included in the present volume. The subjects dealt with include: alchemy, history, development, status; elementary chemistry of sulphuric acid; characteristics and uses; raw materials; production of sulphur dioxide; brief description of the chamber process; dust-settling apparatus; the Glover tower; Guy Lussac towers; the chambers; acid circulation; introduction of nitre; draft; testing; operation; concentration; outline of the contact process; purification of gases; converting; absorbing; converter mass; accounting. The appendix contains many useful data, and the book will be found of value to all who are interested in the manufacture of sulphuric acid.

Heat Treatment of Soft and Medium Steels. By Federico Gholitti. Translated by E. E. Thum and D. G. Vernaci. Pp. 363, ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

This is probably the most complete discussion of the theory and practice of the heat treatment of soft and medium steels that has ever been published. Particular attention has been paid to the effect of various impurities and addition agents upon the properties of the finished steel, and special emphasis is placed upon the fact that commercial heat treatment of steel depends primarily upon the diffusion of carbon and other soluble substances contained, gaseous or solid. The principal headings under which the text is divided are as follows: The Phenomena of Diffusion in Primary Solid Solution; Effects of Diffusion Upon Secondary Crystallization; Diffusion in Austenite as Applied to the Heat Treatment of Steels; Preliminary Heat Treatment of Steel Castings; and Preliminary Heat Treatment of Forged and Rolled Steels. The book is well illustrated, and the translators have performed their part of the work credit-

ably; it should be in the hands of everyone engaged in the heat treatment of soft and medium steels.

Engineering of Power Plants. By Robert H. Fernald and George A. Orrok. McGraw-Hill Book Co., Inc., New York. 595 pp., illus. For sale by 'Mining and Scientific Press'. Price, \$5.

In the preface to the first edition of this treatise the authors stated that the material was compiled for use at the Case School of Applied Science, and was used later at the University of Pennsylvania as the fundamental course in power plant work for all senior engineering students, including mechanical, electrical, chemical, civil, and mining engineers. Besides offering much general material relating to the engineering of power-plants, the underlying thoughts in the preparation of the book were (1) to bring the student a realization of the fact that engineering, although based on the exact sciences, is not in itself an exact science; it requires, on the part of the successful engineer, a natural fund of common sense, and the application of engineering judgment; (2) to give the student some idea of the commercial side of engineering work. It will be found an important reference book for practising engineers; the present edition, the second, brings the material abreast of modern developments.

Ceramics. By A. Malinovsky. D. Van Nostrand Co., New York. 274 pp., illus. For sale by 'Mining and Scientific Press'. Price, \$3.

This little book discusses the weathering, the soaking, the molding and drying of clays, and other technical phases of manufacture. Refractory wares are described; defects are classified and remedies are proposed. Actual reference to the subject of ceramics occupies only a small proportion of the contents. The remainder of the book discusses qualitative and quantitative analysis, as well as a number of subjects indirectly connected with the industry. Tables of logarithms, and other information, are included.

Wilson's Mining Laws, 1921. By Calvert Wilson. Pp. 240, paper. For sale by 'Mining and Scientific Press'. Price, \$1.50.

This useful treatise contains a summary of the mining laws of the United States, Arizona, California, Colorado, Nevada, Oregon, and Utah. General legal information is also given, with models of forms necessary. A complete index is provided.

REVIEW OF MINING

MEETING OF SAN FRANCISCO SECTION OF THE A. I. M. E.

Four valuable papers relating to sundry phases of the application of electricity to mine operation were the feature of the monthly meeting of the Institute held on Friday evening, September 23. The meeting was held jointly with the local section of the Electrical Engineering Society. The papers were: 'Rates of Electricity in Mining Industry', by R. E. Fisher; 'How Operations About a Mine or Metallurgical Plant Can be Scheduled to Fit a Power Contract', by B. B. Beckett; 'The Application of Electric Equipment in Connection With Mining and Milling Operations of the Alaska Gastineau Mining Company', by B. L. Thane; and 'Prevention of Electrical Accidents in Metal Mines', by R. L. Eltringham.

MINING CONGRESS CONVENTION AT CHICAGO

The twenty-fourth annual convention of the American Mining Congress will be held in Chicago from October 17 to 22. In conjunction with the convention there will be held the National Exposition of Mines and Mining Equipment. Among the important questions that will be discussed are the following: The relationships between the railroads and the mining industry, the legal responsibility of labor unions, the benefits or disadvantages of co-operative organizations through a modification of the Sherman Anti-Trust Law, the proper protection of our home industry, the establishment of wise methods of taxation, the increased utilization of metal products, and the development of American interests abroad.

The official announcement of the convention says:

"The twenty-fourth convention of the American Mining Congress will be dominated by a single purpose—to create through its conferences and discussions a program which will represent the needs of the mining industry and which will benefit the nation in the establishment of efficiency and economy in mine production and in the conservation of our great natural resources. Every mine executive, every mine operator and official, every trade and commercial organization, every engineer or teacher, everyone interested in furthering our industrial development is invited to participate in this convention as a partner in an effort to bring about a revival of the mining industry as a means to national prosperity."

In addition to Alaska and Mexico, the States of Arizona, California, Colorado, Oregon, Utah, and Wyoming will be represented by attractive exhibits. There will be about 200 representative exhibits, illustrative of the latest forms of mine-machinery and mine-equipment, at the exposition. It will furnish the mine operator and official a unique opportunity to study the equipment that they need in furtherance of efficient operation. The headquarters will be at the Congress hotel.

IMPROVED OUTLOOK FOR THE AMERICAN SMELTING & REFINING CO.

A slight improvement is reported in the affairs of the American Smelting & Refining Co. The first half of 1921 was not profitable, although the diversity of business helped

somewhat at a time when the copper mines were closing down. With its payroll reduced and the cost of materials decidedly lower, the company has been reducing its losses. From silver and lead, it has been enjoying a rather steady income and some profit, while its copper business has suffered from the low prices at which the comparatively few sales have been made. The company has been producing between 4,500,000 and 5,000,000 oz. of silver monthly, of which about 60% has been derived from foreign sources and 40% from domestic ores. The foreign silver has been sold in competition at the open-market quotations of between 50 and 55c. per ounce. Silver from domestic ores is sold to the United States Mint at \$1 per ounce.

The company has also been a buyer of much of the German silver, which has been brought to the United States from time to time. Its copper production has been averaging about 3000 tons monthly or about one-half its normal output. Since the beginning of the year, when it gave up the sale of all metal but its own, the company has been marketing its copper as produced, so that today it has no unsold surplus from 1921 operations. It still has an accumulation of copper from 1920 to be marketed.

It is believed that the preferred stock will remain in the ranks of the dividend payers even though it be necessary again to dip into surplus account.

BINGHAM MINES COMPANY IS OPERATING AT A GOOD PROFIT

The Bingham Mines Co. has made an excellent showing on its operations in Utah this year. In the first eight months, with August estimated, the company's profits and its equity in those of the Eagle & Blue Bell company have been at the annual rate of \$228,594, or \$2.29 per share, before allowance for depletion, depreciation, and taxes, and \$19,975, or 41c. per share, after these charges. The physical condition of both the Eagle and Victoria properties is better than ever before. Recent development at the latter has disclosed an orebody containing high silver content which has been proved to extend continuously from the 1350-ft. to the 1700-ft. level, running from 4 to 14 ft. wide. This is one of the best orebodies recently opened in the Tintic district. In the past twelve years the Bingham Mines Co. has paid off \$1,500,000 of indebtedness, purchased two properties for over \$1,000,000, and paid dividends of \$675,000, with a net increase of only \$54,510 in capitalization.

GOLD MINING ON THE MOTHER LODE IS FLOURISHING

That conditions along the Mother Lode in California have improved materially and that prosperity in gold mining is on the upward climb is the statement made by Stanley Arnot, superintendent of the Plymouth Consolidated mine, one of the steady producers of Amador county. Arnot states that the cost of materials used in mining are continuing the drop that has been in progress for some time and that labor again is abundant. These two conditions have served to bring about a revival of operations by some of the big producers of former years that were compelled to suspend during the War, and to cause new development

in some properties that have not operated for a long time.

The Plymouth mine, with its 30-stamp mill and re-grinding equipment, is declared by Arnot to be handling a larger tonnage of ore than any other mine in Amador county. Three hundred tons of quartz is being crushed each day in this plant. The ore is low-grade. The Plymouth mine is working with a crew of 200 miners and mill-men.

Discussing conditions throughout the county, Arnot said the Kennedy mine had resumed operation. This mine, near Jackson, has a 100-stamp mill. While the company has resumed operations following a long shut-down due to a fire and following flood, it will be operating on a larger scale soon. The Argonaut mine, companion to the Kennedy, which was also closed by fire and flood, has been operating for some time. Fifty stamps are dropping at present and more will be falling soon.

Development work of an important nature is being done in the Fremont mine. Eyes of Mother Lode mining men now are turned to operations in the Moore mine near Jackson. This mine, said to have been sunk to a depth of about 500 ft. 25 years ago, is being re-opened. Machinery has been installed and the unwatering of the shaft now is in progress. It is understood these operations are based upon reports as to ore conditions in the mine when it was abandoned years ago.

MARKET FOR LEAD ORE AT JOPLIN SHOWS IMPROVEMENT

Sales of zinc ores in the Joplin district during the week ended September 10 approximated 3600 tons, the prevailing price-scale being \$19 to \$20 for first grades. There were a few sales at \$18 and \$18.50, but this was confined to less desirable ores. There were no sales of calamine. Shipments slightly exceeded purchases and the general market trend seemed a trifle stronger than the previous three-week period. The lead-ore market was decidedly stronger, prices advancing to \$55 for 80% grades and the demand appeared unsatisfied at the week end. The market for lead ores was apparently strengthened by the fact that the Ontario smelter, which had been down for some time, again started operations, and the other large consuming interests seemed to be utilizing a larger ore-supply than previously.

The fall months opened with considerable eagerness on the part of ore-producers to do everything in their power to maintain operations at plants that are running or even to increase the number, providing it can be done without capital investment. The unemployment situation has been serious for many months in the field, and only the migration of labor to the harvest fields of Kansas, Nebraska, and the Dakotas made the situation tolerable during the summer season. With the closing of these seasonal industries it is expected that a considerable portion of the labor that had migrated will return and add to the unemployment problem of the field. A canvass of the district last week disclosed 3070 miners employed at underground operations. This total compares with a normal employment of 12,000 to 15,000 men by the zinc and lead industry of the three States.

ARIZONA

Bisbee.—At the Calumet & Arizona property 300 men are still on the payroll; a like number is employed at its associate mine, the New Cornelia. Considerable development work has been under way in both properties, while advantage is being taken of the suspension of production to do some needed repair and improvement work in the shafts at Bisbee. The new Campbell shaft has been concreted down almost to the 16th level, the shaft having been completed and bottomed at 1700 ft. At the Junction shaft the concrete pipe-line is installed from the 2300-ft. level to surface. This shaft, which handles most of the water for the

entire Bisbee basin, is lifting about 3200 gal. to the surface every minute. New Cornelia is producing in a limited way, it having been found inadvisable to close the leaching-plant entirely. Operations at both properties are being conducted at a loss. Experiments are being carried on at the Calumet & Arizona's S5 mine in New Mexico, and at the Verde Central property at Jerome.

Jerome.—The development program that the Shannon Copper Co. is carrying on at its Yaeger mine and its property at Gleeson is exposing better ore than was being uncovered several months ago. While no ore has been shipped from either property for some time, due the smelters being closed, the stock-piles are steadily growing larger, which will mean a substantial sum to Shannon just as soon as shipments start. On ore that is now being taken out of the Yaeger mine, Shannon could today show a profit even with the metal at current low prices. Shannon continues in an unusually strong financial condition. It has between \$390,000 and \$400,000 of net quick assets, equal to better than \$1.30 per share on the stock. Expenses at the Yaeger and Gleeson properties are averaging between \$3000 and \$4000 per month.

CALIFORNIA

Cima.—Promising gold discoveries have been made in this vicinity. The veins are said to be in quartz, and, besides gold, contain silver and lead. Claims have been staked along the strike of the lode for a distance of about five miles. E. J. Ginn was the original discoverer.

French Gulch.—The Atascadero Copper Co. has purchased the Greenhorn group of copper claims situated three miles west of Tower House. The final payment of \$50,000 was made recently. The claims were located in 1916 by Henry B. and J. F. Warren.

Grass Valley.—The Malakoff hydraulic mine, near North Columbia on the San Juan ridge, is to be re-opened immediately. The project is in charge of Abe Hall, a well-known mining man here. He is said to be backed by a group of mining engineers and mine officials of this district. The mine produced many millions by the hydraulic process, but was closed by the Sawyer decision of 35 years ago. For several years it has been under control of W. B. Bourn and associates, who made no effort to work the deposits. The new operators plan to sink to bedrock and then drift along the channel to the point where gold deposits are believed to exist.

La Grange.—The La Grange Gold Dredging Co. has contracted with the Yuba Manufacturing Co. to erect a dredge that will cost approximately \$185,000, to mine its property in this vicinity. Shops and derricks are being erected by the Yuba company preparatory to starting construction.

Placerville.—O. A. Ingraham is operating a 5-stamp mill at the Havilla mine, at Nashville. New ore of good grade has recently been developed.

Randsburg.—The Pittsburg & Mt. Shasta Mining company has purchased the Black Hawk mine. Emil Jonsen will be in charge as general manager, D. A. McCormick, of Keswick, long connected with the company, will be its superintendent. The company, which has interests in the copper belt of northern California, is one of the strongest organizations that has yet entered the Randsburg district. It is understood that development will start at once on the Black Hawk and adjoining claims.

Tuolumne.—At the Phoenix mine, lying south of the Providence, a surface plant was put in operation on September 1. James Leary, who is in charge of the work, will commence sinking as soon as the shaft is unwatered.

COLORADO

Cripple Creek.—The Ajax Mine Leasing Co. has taken a

long-time lease on the Ajax mine. The Ajax property is said to be only superficially developed, although a production of \$5,000,000 is recorded. A number of sub-leases have been let to experienced miners, and shipments have started. H. C. Colburn is superintendent.

IDAHO

Coeur d'Alene.—The Ajax Mining Co., owner of 13 patented claims, in the Lalande district, will drive an adit into its property from the lowest point obtainable in Burke canyon, according to A. C. Bixby, mine manager. A site has been acquired at a point within a few hundred feet of the main highway to Burke, and about a mile east of the town. The erection of buildings and the installation of machinery will be started at once. The cost of developing the mine by a shaft became a problem, considering the increasing expenses, such as electric pumps, transporting timber and supplies up the mountain, and operating hoists and pumps. With the knowledge that a deeper tunnel eventually would

for its benefit — The Mascot Mining Co., recently organized, has installed a 50-hp hydro-electric plant, a new saw-mill, and additional equipment. Active development with 10 men has been commenced.

MICHIGAN

Houghton. It probably will be spring before new hoists are installed in the Seneca and Gratiot shafts of the Seneca property. The matter of new hoists is soon to receive the attention of the directors. In the meantime, development of the Seneca branch will continue. Until the Centennial-Allouez resumes operations, Seneca will continue to have the use of the Baltic mill. Drifts are being pushed forward from the four lower levels of Seneca, northward in the direction of Gratiot with which they ultimately will connect. Copper content varies, but on the whole is satisfactory and averages well with Kearsarge lode 'rock' in neighboring mines. Stoping continues on the 4th level in an excellent quality of ground.

Power-Plant of the Cumberland Mines Co. at Mayday, Colorado

be necessary, it was decided to drive a tunnel now. — The Chicago-Boston Mining Co. proposes to change its name, increase its capital stock by 1,000,000 shares, and buy the property of the Kill Buck Mining Co. with the proceeds, according to notice to stockholders from Donald A. Callahan, president. The capitalization of the Chicago-Boston is 1,500,000 shares, all of which is outstanding. The Chicago-Boston is driving east on the 400-ft. level to pick up the ore found on the 200-ft. level.

Hailey.—The Federal Mining & Smelting Co. has purchased the Baltimore group, an old-time producer in the Wood River district adjoining the Independence. The company has commenced drifting from one of the lower levels of the Independence into this ground. Recent discoveries of new ore have been made. The Independence has been producing almost continuously for about three years. — The Bunker Hill & Sullivan company has been conducting active mining operations for more than 30 days. That the company is well satisfied with the possibilities of the district is evidenced by the options it has taken on adjoining ground and its negotiations for two properties in the same locality. It has erected substantial buildings and is using electric power from a seven-mile transmission line run from Hailey

Directors of the Arcadian Consolidated have decided to continue development work at the property the coming winter, employing a small force. Disclosures in the drift that is being driven south from the 942-ft. level of the New Baltic shaft, to connect with the 900-ft. level of the New Arcadian, continue encouraging. Some minor faulting has been found, but there has been no difficulty in recovering the vein, and the mineralization thus far is described as highly promising. There is no present need of additional financing and this matter will not be taken up until a later date.

Despite the fact that the majority of the mines have been closed for five months there is little evidence of distress in the district. Public relief agencies report that requests for aid are not unusually frequent and as a matter of fact the Houghton County Poor Commission paid out for relief less money, by \$1000, in August this year than in August 1920. An extensive highway-construction program has worked well as a relief measure and in addition to this several hundred men have been given work in extending the Calumet & Hecla water-main from Calumet to Ahmeek and also from Calumet to the Ahmeek mills. There have been no business failures. It is realized, however, that with the cessation of road-work

and other outside operations, it will be necessary to adopt some organized form of relief. The relief organization, which will be largely supported by voluntary contributions, will have its greatest task in the north end of Houghton county or the Calumet district.

MONTANA

Butte.—Increased operating efficiency is being obtained by the Davis-Daly company, for which J. L. Bruce is general manager. It is planned now to have six shifts weekly get out the same amount of ore that formerly required 13 shifts; recently even this ratio was exceeded, more than 400 tons being hoisted. During the War, Davis-Daly hoisted between 250 and 270 tons with a force approximately twice the number at present employed. Costs at present are around \$6.20 per ton, contrasted with more than \$14 in times past. Another noteworthy saving has been effected in the sorting out of waste and the maintenance of a higher grade in the shipments, this serving to effect an economy of about \$6000 monthly.

Cross-cutting is under way on the 750-ft. level of Davis-Daly's Hibernia mine. From the showing of ore on the 600-ft. level and on the 800-ft. level of the Nettie mine of Anaconda adjoining the Hibernia, there is little doubt as to the ability of Davis-Daly to develop ore on the 750-ft. level.

Cooke City.—It is reported that a vein of high-grade ore has been found in the Glengarry mine at Cooke City.

DeBorgia.—After 30 years of inactivity, work is to be resumed on properties of the old Rock Island mine, six miles north of DeBorgia, now known as the Silver Rock, according to Chris Ehrenberg. During early years valuable deposits of silver and lead were found in the old mine. During the summer the new company, composed of Eastern capitalists, has been building three miles of road, making possible the hauling of ore to DeBorgia. Several bridges have been constructed.

Deer Lodge.—The mill of the Champion Mining Co., being operated by the Butte-Jardine Co., is producing 40 tons of concentrate per week. This is shipped to the East Helena smelter, the principal value being in the silver, which averages 250 oz. per ton. The mine is worked through a 1500-ft. tunnel, which taps the old shaft at the 600-ft. level. Approximately 100 men are employed in the mine and mill, and the small town of Champion is flourishing. Miles Blunt is superintendent.

Helena.—The East Helena smelter of the American Smelting & Refining Co. virtually has retired from the east Helena ore field in Butte, the explanation being given that Butte ores are proving too silicious for this plant to treat. The East Helena smelter is of the silver-lead type and does not pay for any copper found associated with the silver-lead ores it reduces. It exacts a penalty for zinc above a certain figure. Mining companies operating in the vicinity of Helena are reporting miners ready to work at \$3.50 per day and this lowered wage with the reduced freight-rates on low-grade ores is expected to promote a revival in silver and gold mining.

NEVADA

Blide. The re-organized Victory company has resumed work following the collection of the first assessment. No work has been done since March. The former work was all done west, or toward the Belcher, from the north-south fault, but now a cross cut is being driven to open the vein east of this fault or toward the Brougher. This work is being done on the 200-ft. level. There is exposed from the bottom of a 500-ft. winze an ore-shoot 25 ft. long, 18 in. wide, and averaging \$70. John Schwable is in charge of the work.

The Tonopah Divide Co. is shipping 50 tons daily to the Belmont mill at Tonopah; the average of ore shipped last

week was \$32 per ton. The Divide Extension has been shipping 33 tons daily to the MacNamara mill, averaging \$68 per ton.

Eureka.—At the Eureka-Holly Extension the head-frame over the Standard shaft is in service. The shaft has been newly timbered down to the 50-ft. level. The ore found 100 ft. south of the shaft averages \$2.06 in gold and 52 oz. silver per ton and 48% lead, according to the assays. Two cars of oil have been received by the Eureka-Holly. A connection between the 500-ft. and 600-ft. levels has been made, and the ventilation is thereby improved. A new and good prospect has been found on the 400-ft. level. On the 600 a drift is in progress to cut a block of ore-bearing ground east of the shaft. A fault intervenes and no ground east of the fault had ever been exploited at such depth, but high-grade ore has just been found. A big tractor is in use, hauling ore to the railway depot.

At the Bullwhacker the old Laird stope is being explored below caved ground, and 2 ft. of good lead ore has been cut. Ore is being hoisted for shipment. The 430-ft. level of the Holly is being extended 250 ft. to intercept an orebody in the Bullwhacker.

The Cortez Silver Mines Co., operating in the northern part of Eureka county, has driven the lower adit over 2400 ft. and encountered more than 2 ft. of primary sulphide in a limestone fissure, at a depth of about 360 ft. vertically below the old workings. The ore is reported to assay from 150 to 200 oz. silver and 0.25 oz. of gold per ton.

Gardnerville.—A winze from the lower tunnel of the Veta Grande mine, 12 miles south of here, has cut the ore-shoot exposed in the tunnel. A shaft will be sunk at once from a point below the portal of the tunnel.

Gold Circle.—The Elko Prince mine continues to develop high-grade ore at depth, a winze sunk 60 ft. below the 750-ft. level continuing in good ore. The Big Chief Con., owned by Clarence Berry and associates of San Francisco, has resumed work and may soon begin building a mill.

Goldfield.—The Goldfield Deep Mines has levied assessment No. 3, at the rate of 1c. per share, delinquent on October 22. The shaft passed a depth of 1000 ft. on September 20. Assessment No. 2, the first general assessment, brought \$82,442, according to the statement of H. G. McMahon, secretary. The expenditures to September 1 total \$179,739, of which \$130,054 was for operation, \$27,482 for equipment, and \$22,202 for properties as follows: Milltown, \$10,000; Goldfield Combination, \$9045; Diamondfield, \$158; office-building, \$3000. Under the item 'operation' are administration, \$15,334; legal advertising, \$7458; development, \$3972; legal services, \$6264; Atlanta Mines Co. expense, \$8683; incorporation expense, \$6279; shaft sinking, \$72,993; traveling, \$1117; telephones and telegrams, \$443.

Hornsilver.—The shaft of the Orleans has been sunk 30 ft. below the 580-ft. level and it is being continued at the rate of 3 ft. daily. The only other work being done is the preparation of the levels above the 580-ft. for further development. From the surface to the 400-ft. level the shaft is in the vein, but at the 400-ft. the vein goes far into the hanging-wall side of the shaft, gradually straightening below this level, and it is expected it will be entered again by the shaft at 675 to 700 ft. No further development work will be done until the sinking of the shaft has been completed.

Klondyke. The Knox Divide is shipping 100 tons weekly from its Golden State property to the Tonopah Mining Co.'s mill at Millers, 15 miles west of Tonopah.

Mina.—The most important discovery since the opening of the main orebody is reported by P. A. Simon, general manager for the Simon Silver-Lead Mines Co. The discovery was made west of the west major fault on the 400-ft. level. While the extent of the deposit has not been de-

terminated as yet, both faces of a 15-ft. drift are in ore. Fifty tons of ore hoisted to the surface averaged: gold, 0.04 oz.; silver, 23.24 oz.; lead, 2.9%; approximate value, \$27.50.

The Minn Mercury Co. will install two new retorts to supplement the two now in operation. A new deposit of crystallized cinnabar has been exposed; the shaft will be sunk deeper.

The West End company of Tonopah recently has taken over, for a price reported to be \$50,000, a group of claims owned by J. M. Krippner and F. J. Barr of Reno, and Martin Pitting and Joseph Jones of Hawthorne. The claims, known as the Mabel group, are on the western extension of the vein in the old Garfield mine, formerly a silver-gold producer. They are 20 miles north-west of Mina. Late in 1919 the men who have sold to the West End made their first shipment. This ore, from the Ida claim, assayed 180 oz. silver and \$9 in gold. Other shipments followed and recently five carloads of ore of a total net value of \$20,000 was shipped. The West End acquired the claims directly from Sol M. Summerfield and George F. Thompson, holders of an option.

Pioche.—The Prince Consolidated has suspended operations on the 800-ft. level until more powerful hoisting and pumping machinery can be obtained. M. C. Godbe, general manager, is inspecting the mine and it is expected he will make an announcement of his plans soon.

Reno.—The Standard Metals Co. will sink the main shaft from the 300 to the 500-ft. level at once and the mill will be closed while this work is in progress. A stope on the 300-ft. level is said to show five feet of \$100 ore.—The Fravel-Paymaster shaft is being sunk to the 500-ft. point.

Tonopah.—Bullion production from this district is at the highest point reached for a number of years; shipments from the mills of the Belmont, West End, Tonopah Mining, and Tonopah Extension, from the second August clean-up, aggregated \$267,500. Of this total the Belmont shipped bullion valued at more than \$94,000, making its total for August \$117,000. The Tonopah Mining and Belmont companies are treating custom ore in addition to that from their mines.—On deeper levels of the Rescue-Eula a large tonnage of good mill-ore has been blocked.

Virginia City.—The Pittsburg Comstock Co., adjoining the United Comstock and acquired recently by H. G. Humphrey and associates, has started work with Al McCoy as manager. A stope near the junction of the Bright Star and Trojan veins in this ground produced \$75,000 from above 80 ft. The lower tunnel, 600 ft. long, will be driven to the vein junction. William Sharp is consulting engineer. The United Comstock haulage tunnel passes near the east side-line of the West Trojan claim, belonging to the Pittsburg Comstock Co., at a depth of 1400 ft.; ore developed here will be accepted by the United Comstock at its mill.—The Comstock Silver Mining Co. has developed a considerable quantity of mill ore in its Scheels group, in the Succor vein, one of the best of the rich cross-fissures extending between the Comstock and Brunswick lodes at the south end. The 10-stamp mill on the company's Overland group is to be remodeled and enlarged. George Drysdale is manager and Frank W. Royer is consulting engineer.—A large force of men is engaged in sampling the dumps, surface, and old workings of the middle mines, including all the properties on the lode between the Con. Virginia and United Comstock. These properties are under option to the Boericke brothers of Philadelphia. Harold Boericke has been spending a fortnight at the property in company with Albert Burch, consulting engineer, and R. B. McGinnis, superintendent.

UTAH

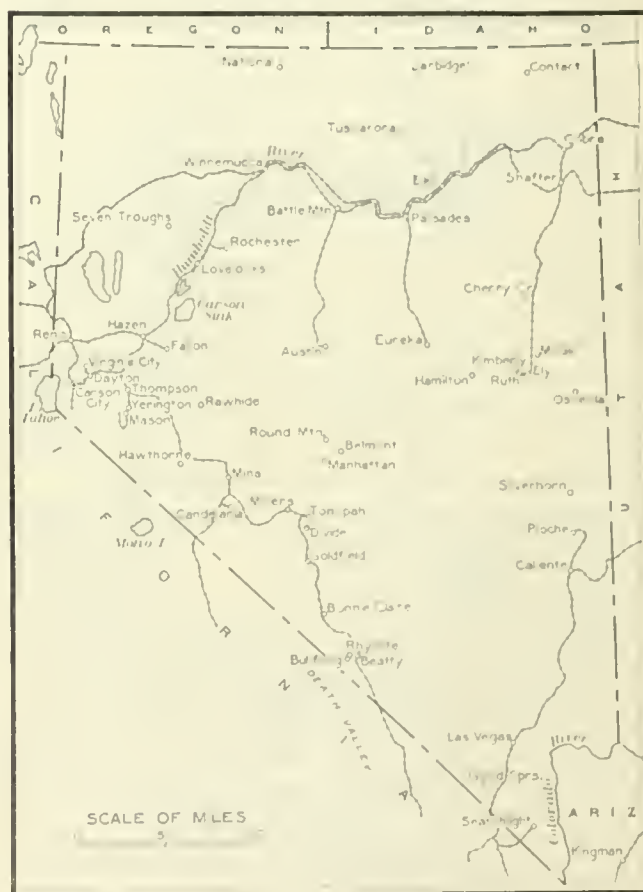

Alta.—The shoot recently found at the property of the Alta Tunnel & Transportation Co. continues to improve; the

ore is at the top of No. 3 rulse and has a width of eight feet. Samples show from \$11 to \$55 per ton in silver and lead. The ore is a carbonate, easily mined and, owing to the absence of water, can be handled cheaply. F. V. Bodfish, manager, is continuing development work to ascertain the length of the deposit.

American Fork.—A recent heavy rain on the east slope of Boxelder mountain in American Fork canyon exposed a 4-ft. vein of copper ore. The discovery was made by Earl Devey and Arthur McDaniel, who filed on a location.

The American Leasing Co. is now the heaviest shipper in this district. Shipments from their leases average about 70 oz. in silver, with some gold and lead. The Wild-Merced lease in the Dutchman mine is also extracting ore of good grade. Recently a high-grade lead-carbonate ore was found. This lease has been shipping zinc ore for some time.

Big Cottonwood Canyon.—Encouraging reports come from

Map of Nevada

the Twin Peaks mine in this district, of which S. A. Parry is manager. The tunnel is being driven in a bedded vein, and recent picked samples give assay returns of \$3 in gold, 30 oz. in silver, and 5% lead.

Enreka.—E. J. Raddatz, president of the Tintic Standard Mining Co., denies rumors recently circulated to the effect that the mine has suffered several cave-ins and that the chloridizing plant is a failure. These rumors have been circulated in connection with the recent weakness in quotations for Tintic Standard stock. Mr. Raddatz states that about three months ago there was a cave-in, but the shipping records prove that it did not interfere with ore production. As to the mill, for several months past it has been making an average extraction of 83% of the silver, treating an average of 140 tons per day. An experimental plant with a capacity of 25 tons per day has been built recently to save

the lead in the ore. An average of 45 cars of ore is being shipped per week, 65% of which goes direct to the smelter and the remainder to the mill. The company is employing 300 men, and is engaged in an extensive exploratory campaign, according to Mr. Raddatz.

Development work at the Eureka Lily property is being done on the 500-ft. and 1400-ft. levels. The drift on the 500-ft. level has cut bunches of low-grade ore. At present high-grade ore, 18 in. thick, is showing in the face of the drift. Assays of this ore give returns of 39.5% lead, 24 oz. silver, and 60c. gold. On the 1400-ft. level, a rich shoot of ore was recently entered, which assayed 33.8 oz. silver, \$12 gold, and 26.2% copper.

Ore shipments for the week ending September 10 totaled 137 cars, as compared with 155 cars for the preceding week. The Tintic Standard shipped 42 cars; Chief Consolidated, 34; Victoria, 14; Dragon, 10; Eagle & Blue Bell, 9; Iron Blossom, 6; Swansea, 5; Centennial-Eureka, 4; Gemini, 3; Iron King, 2; Colorado, 2; Bullion-Beck, 2; Mammoth, 2; Gold Chain, 1; and Sunbeam, 1.

Koosharem.—Preparations are being made by C. D. Ray of Salt Lake City and associates to resume work at the Indian Red Paint mine in Sevier county, near here. The deposit at this property is a deep red clay, with an aluminum base, and almost entirely free from silica. The deposit is said to be one of the best of its kind in the United States, and the owners of the property have made a favorable contract with calcimining concerns on the Pacific coast. The deposit is near the surface and can be excavated with scrapers.

Logan.—Work is to be started at the property of the Mineral Point Copper Co. in East Paradise canyon, according to Andrew Madsen, superintendent. Some time ago a tunnel, 282 ft. long, was driven at a shallow depth. Recent work cut 20 ft. of gold-bearing quartz. One hand-picked sample gave returns of 77.2 oz. gold and 6.6 oz. silver. The property is about seven miles from a railroad.

Park City.—Ore shipments for the week ending September 10 totaled 1354 tons, of which the Judge companies shipped 524; Silver Coalition, 442; Ontario, 388. Shipments for the previous week were 1914 tons.

Salt Lake City.—A brief report has been compiled by Carl A. Allen, district mining engineer for the U. S. Bureau of Mines, at the request of officials of the Bureau at Washington, on the present status of employment in the mining industry. Allen states that at present the three smelters operating in this State employ 1300 men, as against 2300 a year ago, 2500 two years ago, and 5000 employees three years ago. The working forces in the Park City and Tintic mines are about normal. Very few men are applying for work at the mines and there is even a scarcity reported of good machine-men. Mr. Allen's investigations lead him to believe that most of the men thrown out of employment by the closing down of the Utah Copper, Utah-Apex, and Utah Consolidated properties at Bingham obtained work on farms and in road construction, although a large number have left the State.

BRITISH COLUMBIA

Allee Arm.—A body of high-grade ore is reported to have been opened up on the Silver Standard and the same may be said both of the Queen and the Moose properties.

Hope.—The Eureka mine, situated in the Cheam mountains, and one of the oldest lode mines in the Province, has been re-opened. Messrs. Sperry and White, of Vancouver, have acquired control of the property and are planning to invest from \$75,000 to \$150,000 in development and plant. Confidence is expressed that the old property will become a large producer of silver.

Princeton.—The Princeton Mining & Development Co. is engaged in the opening up of a promising property situated

east of the town of Princeton. The ore contains copper, gold, and silver. The richer orebodies have given returns of: copper, 16.9%; silver, from 2 to 12 oz.; and gold, from 45c. to \$2.50. Three tunnels have been driven and mine plant and accommodation has been provided.

Stewart.—The Portland Canal Mines Co. has been organized in the United States, as a holding company for the Daly Mines, Ltd., in British Columbia, to take over and operate the Big Missouri mine. T. H. Wilson, of New York, and Pat Daly are at the mine in consultation with regard to future development. Exploration work is to be started at once and continued through the winter, Pat Daly acting as superintendent.—Grant Mahoot has struck rich ore at the Divide group, at the head of Salmon river. Assays of some of the best ore have run up to more than 2000 oz. in silver per ton.—R. L. Clothier has a crew of men at work on the trail and is cutting brush for the new tramway at the Silverado group. Some 500 ft. of snow-shed is being built. Work is being rushed with a view to keeping the mine in operation during the winter.—The new wharf that was built last year by the Dominion government is altogether inadequate for the business of this place. It is to be extended at once and the warehouse on it is to be enlarged.

Trail.—The ore receipts for the week ended September 1 at the smelter totaled 6552 tons, 6287 tons coming from the Consolidated company's mines. The other shippers were: Josie, Rossland, 89 tons; Knox Hill, Republic, 77; Little Maime, Ainsworth, 11; Paradise, Windermere, 45; and Spokane-Trinklet, Ainsworth, 43. The Consolidated company has suspended production at its Sullivan mine, at Kimberley, temporarily, in order that repairs to haulage-ways and other parts of the mine may be made. The single men have been laid-off and the married men are doing the repair work. It is expected that production will be resumed within a week.

MEXICO

Chihuahua.—La Nortena, a group of 15 mining claims, situated on the Roncesvalles hacienda, in the municipality of Las Cuevas, has been taken over by Ramon C. Reyes. The ores of this district contain gold, silver, and lead.—Carlos Perez has filed with the mining agent at Chihuahua city application for the Guadalupe group of mines, situated in the Guadalupe mountains in the municipality of Aldama.—Some new silver-lead properties have been located by Hilario Perez, to be titled under the name of La Reina del Cobre. The survey is being made by Jose M. Licona of Chihuahua.

Activity is also noted in the Chinipas district where Charles Ballow, representing Albert H. Davison and George Johnston, is operating extensively. Ballow has recently located three different groups in that vicinity, the Santa Rita, situated in the Santa Barbara camp, the Elena, and the Santa Barbarita, all of which contain bodies of gold and silver ores. Some of the old workings will be cleaned out and new shafts will be sunk on the principal veins which traverse the properties.

Las Chispas.—A shipment of 121 tons of ore and concentrate by the Minas Pedrazzini Gold & Silver Mining Co. was made during this month. The ore is freighted by mules and burros to Nacozari, the nearest shipping point. This shipment will net about \$65,000. Steady shipments have been made for over two years, approximately 500,000 oz. of silver and 2800 oz. of gold having been produced.

Nacozari.—The La Gran Republica, Lady Goodlander, and Tres de Abril claims are being opened up by the Sonora Development Co. of Kansas City, Missouri. This property is situated about four miles east of the Pilaes mine of the Moctezuma Copper Co. and was worked in several places by the Spaniards. Several bodies of high-grade ore have been mined during recent years. Work has been pursued during the past year to develop low-grade ore for milling purposes.

The ores carry gold, silver, lead, and copper. R. W. Brown is manager.

Saltillo.—The State of Coahuila has placed a tax on all ores mined in the State, the tariff being as follows: gold and silver, 2% of the gross value; copper, 1½%; lead, 1½%; and zinc, 1½%. The tax is to be paid on the gross production, the price of mining and freight and treatment-charges are not to be deducted.

Leopoldo de la Peña is developing some zinc mines in the Mimbres canyon near Parras. There are six claims in all composing La Esmeralda group.

The delinquent share-holders of El Destino Mining Co. are advised that unless all over-due assessments are paid within the next 15 days the stock will be declared forfeited. Payments may be made to Manuel V. Valdez, treasurer of the company, who has offices in the city of Saltillo.

The report of the Temiskaming, covering a period of 18 months ending June 30, during which the company's mill operated only 11 months, shows an operating deficit of \$135,765. The net production was \$179,294 and other income \$51,479, making a total revenue of \$220,773, and operating and other charges amounted to \$366,539.

Ottawa.—A report issued by the Dominion Bureau of Statistics states that the total gold production of Canada for the first six months of 1921 amounted to 396,391 oz. with a value of \$8,194,129, representing 52% of the amount mined during 1920. A feature of the market for gold is that all sales to the Royal Mint at Ottawa are paid for in New York funds. Ontario produced 73.5% of the total Canadian output, British Columbia ranking second with 22.9%, and the Yukon third with 3.3%. Quebec, Manitoba, and Nova Scotia combined produced 0.3%.

ONTARIO

Beaver House Lake.—At the Argonaut about 100 ft. of drifting has been done on the vein found on the 350-ft. level. Assays obtained at intervals of 5 ft. have shown gold content averaging \$15 per ton.

Cobalt.—The Nipissing during August mined ore of an estimated net value of \$172,931, of which \$147,552 was silver and \$25,380 cobalt, and shipped bullion from Nipissing, and custom ores of an estimated net value of \$236,558. At the second level of shaft 63 a vein was found having a width of 2 to 3 in., which assays several thousand ounces per ton. The Nipissing has taken an option on two Porcupine properties, the Rochester directly north of the Hollinger, and the Edwards claim a little east of the Dome. Diamond-drilling on both is in progress.

The La Rose is drifting on the new high-grade vein on the Violet property at the 570-ft. level. The vein is widening out considerably and shows increased enrichment as it is followed.

Porcupine.—It is officially stated that the Dome Mines is now treating an average of 840 tons daily, recovering approximately \$6.17 per ton. Adding the premium of American funds this gives an income of approximately \$6.80 per ton or at the rate of \$5712 per day.

The report of the McIntyre-Porcupine for the year ended June 30 shows net earnings of \$1,088,513, compared with \$1,280,232 for the preceding year, the decrease being due to the curtailment of operations during the winter owing to shortage of power. After deductions for taxes and depreciation a net profit of \$815,530 was transferred to surplus. Ore was produced to the amount of 171,916 tons of an average value of \$11.67 per ton and gross value of \$2,005,672. A considerable increase is shown in the ore-reserves, which were estimated at 624,422 tons valued at \$6,392,394. J. P. Bickell, president, says "We feel warranted in increasing our milling facilities by the addition of a new 500-ton unit, part of which will be used to bring our production up to 1000 tons of ore per day."

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Max Kraut is at Mexico City.

W. J. Loring is on his way to Boston.

B. M. Snyder is on his way to southern Mexico.

Frank D. Pagliuchi has returned from New York.

Courtenay De Kalb is now residing at New Orleans.

R. W. French, of Oakland, is at Newport, Delaware.

D. W. Brunton is sojourning at Long Beach, California.

R. N. Dickinson has been geologizing in Siskiyou county.

Fred G. Farish has been at Telluride, Colorado, for several weeks.

Walter L. Reid and R. A. Hardy have been at Juneau, Alaska.

Walter H. Aldridge is now at 41 East 42nd street, New York City.

L. S. Cates is at Boston, having been called there by the death of his mother.

Harold A. Titcomb has returned from Palo Alto, California, to Farmington, Maine.

F. G. Cottrell is expected at Washington, on his return from Europe, about October 18.

Henry H. Ray is at Nevada City, California, as engineer to the Yuba Development Company.

Herbert R. Hanley has returned to San Francisco from a visit to the smelter at Trail, B. C.

Robert M. Keeney has moved from Leavenworth, Washington, to Somersville, Connecticut.

C. W. Purington arrived at Boston on September 14, and is expected in San Francisco shortly.

W. B. Donoghue, of the Cerro de Pasco Copper Co., Casapalca, Peru, was recently in New York.

Charles B. Croner is at Alpine, Idaho, on special metallurgical work for New York capitalists.

F. E. Calkins, of Globe, has completed his examination of the Lincoln mine, near Prescott, Arizona.

H. Foster Bain and T. T. Read will be entertained by the local section of the Institute on Tuesday, October 4.

C. M. MacNeill, president of the Utah Copper Co., visited the company's properties at Bingham and Garfield last week.

E. J. Atkison has returned to Los Angeles from the Bishop Creek Milling Co.'s property in Inyo county, California.

J. Mackintosh Bell has returned from the Alberta oil region and is now at the Keeley mine, near Porcupine, Ontario.

L. C. Penhoel is at Metahuala, San Luis Potosí, Mexico, where he is erecting a mill for the Santa Maria de la Paz company.

Raymond F. Bacon has resigned as director of the Mellon Institute and will be succeeded, in January next, by E. R. Weideln.

H. Hardy Smith writes from Sydney, Australia. He is on his way to South Africa, where he expects to remain for some time.

Morton Webber entertained the Warren District Luncheon Club at Lubee recently with a talk on the diamond mines of South Africa.

Frank S. Allen, of Silver City, Utah, has been appointed general superintendent of the Knight properties in the Tintic district.

John I. Lane, mining engineer for the American Smelting & Refining Co., has moved from Saranac Lake, New York, to El Paso, Texas.

Galchi Yamada, Assistant Professor of Metallurgy in the Kyoto Imperial University, has concluded his research into

the flotation of coal, at the U. S. Bureau of Mines station at Seattle, and is now at Minneapolis.

Fred B. Ely, together with a party of geologists, has left for the western part of Mexico to make an extensive examination for oil and gas.

O. W. Freeman, professor of geology, has moved from Lewistown, Montana, and is now at the Stockton High School, in California.

Frederick Lyon, formerly vice-president of the U. S. Mining, Smelting & Refining Co., was in San Francisco this week on his way to the Orient.

Henry J. Kruse, of Crosby, Minnesota, has arrived in San Francisco, after traveling in his own automobile from Joplin to Seattle and thence hither.

Oba Wiser has returned to El Paso, Texas, from Kingman, Arizona, where he has been investigating the treatment of the complex ore of the C. O. D. mine.

Frank R. Wicks, consulting engineer of Los Angeles, has returned home after spending the past eight months at the Royal Tiger mine, at Breckenridge, Colorado.

Bailey Willis, Professor of Geology in Stanford University, addressed the Engineers Club of San Francisco on the subject of 'Earthquake Engineering' on September 15.

J. R. Mongin has resigned as Chicago representative for the Mine & Smelter Supply Co., to become mill manager for the Ore Chimney Mining Co., at Northbrook, Ontario.

B. A. Middlemiss, formerly mine manager and, later, assistant general manager for the Chile Exploration Co., Chuquicamata, Chile, has returned to the United States and will take up professional work in this country.

Arthur J. Hoskin has moved from Denver to Urbana, Illinois, where he is Assistant Professor of Mining in the University of Illinois and is engaged in coal-mining investigations in co-operation with the U. S. Bureau of Mines.

E. Roche Rice, previously in charge of the operations of the Van Dyke Copper Co., at Miami, Arizona, is now in partnership with L. H. Foster, of Kingman, Arizona. The firm will be known as Rice & Foster, mining and civil engineers.

Tudor S. Rodgers has resigned as chief chemist and assistant superintendent for the Tecopa Consolidated Mining Co., at Tecopa, California, and has opened law offices at Salt Lake City. The firm name will be Rodgers & Rodgers, and they will specialize in mining and corporation law.

E. H. Wells, who conducted special geological investigations for the Chino Copper Co. for the last two years, is the new president of the New Mexico State School of Mines at Socorro. Other newly elected members of the faculty are: W. T. Quayle, engineer of metallurgy, a graduate of the Colorado School of Mines; J. W. Jourdan, recently professor of civil and irrigation engineering at the New Mexico College of Agriculture and Mechanic Arts; R. E. Bowman, who has been chemist for the Cleveland Cliffs Iron Co. and the Republic Iron & Steel Co.; W. C. Ramlow, engineer of mines, from the Colorado School of Mines; C. W. Vaupell, who was on the geological staff of the Anaconda Copper Co.; and E. C. Studley, until recently field-engineer for the Weiland Engineering Co.

OBITUARY

Alton L. Dickerman, one of the foremost mining engineers in the United States, died at his home in Colorado Springs on September 15. He was born in Stoughton, Massachusetts, in 1850. He represented John D. Rockefeller in the development of the iron mines in Minnesota and also was a pioneer in the copper region of Michigan. For years he represented Marshall Field, of Chicago, in Mexico and Alaska. The Hecla and Calumet copper mines also are included in his early discoveries. He is survived by a daughter, Miss Foster Dickerman, of Colorado Springs, and a son Alton L. Dickerman, of New York City.

Zinc-dust, cents per pound.....	9

EASTERN METAL MARKET

(By wire from New York)

September 19—Copper is quiet and firmer. Lead is active and strong. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 40.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

NICKEL

Financial statements of the International Nickel Co. always have to do with dollars rather than quantities of metal produced or sold, but an insight into the physical end of its business may be gathered from government figures showing a tremendous falling off in receipts of nickel ores and matte into the United States, where the company does its refining. The drop has been more precipitate during the past few months than in the later months of 1920, as July imports were about 2,500,000 lb., against nearly 5,000,000 lb. a year ago. From its high record the arrivals of nickel ores and matte have dropped as follows:

Year ended June 30	Pounds	Value
1919	52,911,658	\$9,740,693
1920	39,015,625	6,848,090
1921	22,077,238	4,971,062

In July there was received in this country from abroad but 225,823 lb. of nickel against 1,649,343 lb. a year ago, and in the seven months to the end of July there had reached here but 2,023,681 lb. in comparison with 25,956,071 lb. in the same period of 1920.

THE MARKET FOR PLATINUM

"Platinum is now firm at \$79 per ounce. It was worth \$3 in 1893, rose to \$158 in December 1919, and fell to \$72 in April of this year. A fair minimum, for the next two years at least, would be \$100 per ounce." This statement is made by Arim Meluk, a Syrian merchant from Cartagena, one of the Colombian ports on the Caribbean, who with Carlos Rume is now in New York. The two firms A. & T. Meluk and Rume Hermanos, purchase and export 70% of platinum mined in Colombia, except that dredged by the Americans, says the Boston News Bureau.

Mr. Meluk bases his estimate for 1922 on these premises: In 1912 Russia exported 300,000 oz., Colombia 12,000, and other countries 15,229 total 315,229 oz. at an average price for the year of \$15.55. In 1919 Russia exported 30,000 oz., Colombia 35,000 other countries 2180, total 67,180 oz. at average price of \$114.61. In 1920 Colombia exported 28,757 oz. and other countries 54,124 total 82,881 oz. at average price of \$110.00.

A small part of the large amount received in the United States from other countries may be from Russia, but is mostly composed of war accumulations by European governments. Now unloading their stocks. During the first six months of this year they sent us 13,771 oz. and Colombia 13,406, total 27,177. Except some very small shipments from Canada—in June 170 oz.—all new platinum is coming from Colombia now, say 30,000 oz. against 12,000 in 1912. "The world requires much more platinum than in 1912," says Mr. Meluk. "More instruments of precision are manufactured now and there is a much greater demand for platinum jewelry. Diamonds look better mounted in platinum, and are safer in that setting."

Native production in Colombia is diminishing more quickly than is apparent from figures of total production: 35,000 oz. in 1919 and 27,000 in 1921. American dredges mine about 6000 oz. per year. Their output is not decreasing. Native production has fallen with the price from 29,000 oz. in 1919 to 21,000 oz. in 1921, say 28%.

Diminution in production must surely continue unless there is an improvement in price. Colombian exporters of platinum do not control the output of the mines. The negroes of the Choco do that. They can always find enough gold to live upon within easy distance of their homes, but platinum is very scarce and they sometimes waste much time searching for a place where bedrock is not too deep for their primitive methods of excavation. Without the stimulus of a high price they prefer to wash the gravel in the streams for gold."

MONEY AND EXCHANGE

Foreign quotations on September 20 are as follows:

Foreign	Cable	3 Months	6 Months
Sterling, dollars	3.72 1/2	3.73	7.10
Franc, cents	7.12	4.25	0.98
Lira, cents			
Mark, cents			

Eastern Metal Market

New York, September 14.

The tone of all the markets continues good; as September progresses optimism and business slowly increase.

Prices for copper are a little higher but the volume of buying for domestic consumption is not heavy.

The tin market is quiet and steady.

Lead is in good demand and prices have again advanced.

Demand for zinc is slightly better and prices are a little firmer.

Antimony is a little lower.

IRON AND STEEL

An advance of \$2 to \$3 per ton in the prices of the American Steel & Wire Co., effective September 10, has broken the long succession of declines in steel products. Prices for wire have been the lowest on the list in relation to cost, and the fact that there has been little cutting in the past two months seemed to indicate an effort to turn the tide. Independent producers have followed the Steel Corporation advances, and all mills made large bookings at the old prices before the advances went into effect.

The heavy influx of wire and wire-nail orders just before the advance showed the country to be bare of stocks to a degree never known. Jobbers covered 60 days requirements while manufacturing consumers in many cases bought for longer periods. Wire fence, in view of low agricultural buying power, remains at the old price.

The Steel Corporation's wire production, in response to the re-stocking orders, has gone up 40% of capacity and promises to increase further. In sheets and tin plate the corporation's rate is still 50%. For all subsidiaries the average is 33%, against 30% in August.

A reduction of 298,000 tons in unfilled orders in August has a more favorable construction than was generally given when it is stated that shipments were 100,000 tons more in August than in July.

That the consumers of independent steel companies also called for increased shipments last month appears from a steel-ingot output for the country in August of 1,351,628 tons. At 27 working days this was 50,060 tons per day, or 31% greater than the daily rate of 38,126 tons for the 25 working days in July.

While reports are not of one tenor, demand on the whole is better than in August, indicating that July was the lowest month of the nine. Apart from wire, prices tend lower, the heavy products, plates, shapes, and bars lagging most.

COPPER

The principal unfavorable feature of this market is the absence of any real domestic buying power. Inquiry is reported as better, but it does not result in purchases except in limited amounts. Foreign buying is good and it is a striking fact that, according to official statistics for the first seven months of this year, Germany not only has been the heaviest buyer, but she has purchased more than the combined purchases of any two other countries. Therefore these statistics confirm a report which has been current in the market for some weeks. Prices generally have stiffened, electrolytic copper for early delivery being quoted at a minimum of 12c, New York, or 12.25c., delivered, from certain sellers with several large producers still out of the market. Lake copper is quoted at 12.25c., delivered, with some sales recorded.

TIN

The week has been a quiet and uninteresting one. Demand from consumers and dealers has been light as com-

pared with previous weeks. There has been a little buying from London when the prices here ruled below parity, and on the New York Metal Exchange there were two sales, one of 25 tons Straits tin for July-August shipment at 27c. and one of 25 tons December delivery at 26.62½c. Spot Straits tin in New York yesterday was quoted at 26.75c. or ¼c. below last week and prices in London yesterday were about £5 below those of a week ago, with spot standard at £156 12s. 6d., future standard at £158 15s., and spot Straits at £157 7s. 6d. per ton. Arrivals thus far this month have been 2075 tons with 2085 tons reported afloat.

LEAD

The feature of the week has been another advance by the leading interest on September 9 to 4.60c., New York and St. Louis, an increase of 10 points. This is the second advance in two weeks. It is stated to have been accompanied by heavy buying so much so that the leading interest is not as heavy a seller as recently. The outside market is quoted at 4.60c., New York, or 4.40c., St. Louis, at which levels a good business is reported.

ZINC

The market is quiet but steady at 4.20 to 4.25c., St. Louis, or 4.70 to 4.75c., New York, with little desire shown by some producers for business at that level. There is no active demand, though some consumers are asking for prompt shipment, particularly galvanizers. One seller regards the market as firmer and slightly higher.

ANTIMONY

There is very little interest in spot or future metal. Quotations are largely nominal at 4.45c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

The leading producer continues to quote virgin metal, 98 to 99% pure, at 24.50c., f.o.b. plant, while the same grade from importers is available at 19 to 20c., New York.

ORES

Tungsten: The market is devoid of interest and quotations are nominally unchanged at \$3 per unit and upward, depending on the grade of concentrate, the delivery, and the amount.

Ferro-tungsten: This market has undergone no change and prices continue nominally the same.

Molybdenum: There is no business heard of and prices are still nominal at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese Ore: Stagnation rules with high-grade foreign quoted nominally at 20c. per unit, seaboard.

Manganese-Iron Alloys: British ferro-manganese has been reduced to \$58.35, seaboard, by one British maker, and others will probably follow suit. Inquiry aggregates about 500 tons in 100-ton and smaller lots, but no inquiry is reported. Spiegeleisen is quiet at \$25 to \$26 per ton, furnace, for the 19 to 20% grade.

Ferro-silicon, 50%, is quoted at \$60 to \$65 per ton, delivered, with demand light.

Stocks of crude and refined oil combined, in the United States at present, total 270,261,000 bbl., of which 188,162,000 consists of crude and 82,099,000 refined. Refined-oil stocks include 17,872,000 bbl. of gasoline, 10,358,000 of kerosene, 29,730,000 of gas and fuel-oil, and 6,211,000 of lubricants. At the present rate of consumption, and allowing for three months working supply as a minimum, these stocks are a little more than 4½ months supply.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

HARDINGE COMPANY ISSUES REVISED BULLETIN

Owing to the large demand for literature, the Hardinge Co. has found it necessary to revise Section No. 1 of its No. 7 catalogue, which is now available. This section deals with the principles of operation of the conical mill, and gives a general description of its uses in the industrial, mining, and special fields. Those wishing copies should state in what class of grinding they are interested, in order that they may receive information dealing with their particular class of requirements. In general the advantages of the conical mill are pointed out as follows:

1. Power for a given output is saved as the energy is roughly proportioned to the work performed.
2. The range of grinding for a given size of mill is large, as the different sizes of grinding media and material are segregated, thus presenting no interference with one another.
3. The capacity for a given unit is large, since the ground material is forced forward as soon as produced by the classifying effect of the discharge cone.
4. The wear is slight, as less grinding media are required to effect a given reduction and those that are used do effective work, which saves the lining as well.
5. The conical shape ensures extreme rigidity and simplicity of construction. Mechanical troubles during operation are almost unknown.
6. The physical characteristics and fineness of the product can be controlled, owing to the many different methods of operating the conical mill.
7. The floor-space and head-room required for a conical mill installation is unusually low, due to the compact method of driving and the fact that the mill is self-contained.
8. Owing to the 'truss' construction of the conical mill a great weight of metal is not required to ensure sufficient strength. This lighter construction saves in the cost of transportation; also lighter foundations may be used.
9. The conical mill is a slow-speed mill with very few moving parts and requiring but little lubrication to ensure efficient operation and reducing the possibility of burning out bearings to a negligible quantity.
10. The mill is water-tight when used for wet grinding, and dust-tight for dry grinding, thus ensuring a clean and healthy plant.

ENGINEERING TABLES THAT ARE WORTH HAVING

We have seldom seen more information of a practically useful nature packed into 20 pages than we find in a recent publication of the Aldrich Pump Co., of Allentown, Pennsylvania, that has recently come to hand. It is called 'Pump Data 50—Engineering Tables'. It is immaterial who made your pumps; this book will be of inestimable service to you if you have any kind of a pumping problem to solve. The first page, for instance, gives a graphic representation of the distribution of energy from the coal-pile to the pumping unit, by way of the boilers, turbines, generators, transmission lines and motors, and the comparative power cost of operating a pump at 60% efficiency and at 90%. This is

followed by tables of 'useful information' that are truly useful. These concern the properties of water and oil, heads and lifts, sundry tables of equivalents, pump-capacities, plunger loads, friction-losses and coefficients, nozzle-discharge, power-transmission, electrical data, pipe data, pumping costs, and sundry other matters, all presented in convenient and usable form.

MINE VENTILATION

Automatic mine-doors, which have been generally adopted as standard equipment by many coal-mine operators, are finding a wide application in metal-mine operation. Whereas a few years ago, automatic doors were looked upon with skepticism by mine operators and in some States were not allowed, today they are recognized as a decided improvement; State laws frequently have been changed to permit of their use. The number of accidents has been reduced by the use of automatic mine-doors and their positive action

Canton Automatic Mine-Door

does not permit of mistakes, loss of time, and contamination of air; moreover such doors have made possible the elimination of door-boys whose work in the past has resulted in numerous fatal accidents to themselves and an inefficient control of the underground ventilation.

The American Mine Door Co. of Canton, Ohio, was a pioneer in the development and application of automatic mine-doors. The inventive genius of N. K. Bowman and the co-operation of progressive mine operators has resulted in the use of automatic doors for a number of years past in the coal and metal mines of both this country and of Europe. The American Mine Door Co. employs ventilation specialists who will advise with mine operators as to their ventilation problems and make recommendation for the proper control of underground air currents.

The automatic mine-door is built upon scientific principles and is thoroughly practical and fool-proof. It will operate under adverse condition, mud and water not excepted, and without the use of that annoying and unsatisfactory evil—the trapper boy.

The Canton automatic mine-door is made with the best material and workmanship. Every part is designed and constructed to withstand, with a big margin of safety, the

hardest kind of rough usage. It is constructed in a modern plant and under the personal supervision of men who know just what is required for underground operating conditions. Although designed to be opened by the wheels of the car, the adjustment is so perfect that it opens readily and easily to the man passing through the mine on foot and closes instantly afterward. Under all conditions it is sure to open and sure to close.

In addition to the manufacture of automatic mine-doors, the company makes a complete line of doors for mine use. Doors for man-ways and other underground use which are not automatic but are operated by hand-levers or operating pedals are included. The American Mine Door Co. has published a booklet on mine-ventilation, which contains details regarding the use and operation of mine-doors; this will be sent upon request.

NOVO AIR-COMPRESSOR UNIT

The Novo Engine Co. is distributing its new catalogue, No. 921, just received from the publishers. This catalogue has been revised and brought up to date in all respects, featuring in addition to the line shown in the former cata-

logue new designs of pumps and hoists of large capacities, and an 80-cu. ft. compressor outfit. The latter is assembled with fan and radiator and a forced-circulating water-cooling system for both engine and compressor. It is shown in the accompanying illustration.

ELECTRIC SMELTING OF IRON ORE

By Frank Hodson

Generally speaking, it may be said that where a market exists for either pig-iron or finished steel, in the vicinity of good iron ore and cheap water-power, the electric smelting furnace has a scope. If it so happens, as is the case on the Pacific Coast and in countries where iron is not made, that material used is subject to heavy freight-charges, then the electric smelter is put on favorable terms.

At present all electric smelting furnaces may be broadly divided into two groups—those using open-top furnaces, in which no attempt is made to make use of the escaping gases, and the Swedish 'Electrometall' type of furnace, in which the smelting is done in a closed chamber. The gases and products of combustion pass through a central shaft, through which the charge is fed down to the final reduction zone. The use of these gases materially assists in the quick reduction of the ore and of course is economical, as compared to an open-top furnace. This type of furnace has been in successful commercial use in Sweden and Norway for the past ten years, and large plants with the 'Electrometall' smelter are now being constructed in Italy, Japan, and Brazil.

Some of the furnaces at present constructed have a kilo-

watt capacity of 5500, but, in the writer's opinion, an improved design of furnace will make it possible to have furnaces of this type of double the present capacity. Interest is now being shown on the Pacific Coast in electric smelting, and as an indication of the immense strides that have been made in Europe in the last ten years in this electric shaft-furnace, I would mention that a total of 27 furnaces installed have a rated kilowatt capacity of 99,700. Brazil is now erecting two of 3000 kw. each, this being the first installation in the Western hemisphere. Others are to follow the present installation. In this respect Brazil is showing steel-men in the United States the vision ahead. The U. S. Electric Steel Products Co. has recently announced its intention of constructing a large electric smelting plant on the Pacific Coast.

'METALKASE' MAGNETIC BRICK

'Metalkase' brick for lining open-hearth and electric furnaces consist of square or round soft steel containers, open at the ends, filled solidly with fine-ground dead-burned magnesite of the highest quality. 'Metalkase' are firmly packed and strongly bonded within the casing and will withstand rough handling. The square sections are 2½ in. on a side and the round 3 in. diam. Both types are made in 9, 13½, and 18-in. lengths.

For bulkheads the round 'Metalkase' 13½ in. long are preferred. They are laid in H. W. R. Co. furnace magnesite, barely moist enough to be worked with a trowel, and with the metal surfaces in contact. The 'Metalkase' are laid the entire width of the bulkhead from the floor-line to the top. There is a decided advantage in building the 'Metalkase' entirely across the wall, as this method of construction reduces to a minimum the cutting action of the gases at the corners and adds to the life of the bulkhead. A water-cooler or a course of chrome brick at the floor-line adds to the life of the bulkhead. A return water-pipe at the base of the cleaning-hole will act as a rest for the scraper and protect the refractories.

In bulkheads they have much longer life than silica; decrease repair costs; reduce the number of hot jobs; diminish the amount of slag in slag-pockets. In port walls they simplify operation by keeping the port section uniform. 'Metalkase' brick have the high melting-point and slag-resisting qualities of magnesite brick; they do not spall; they are unaffected by iron-oxide vapors. Incipient fusion of the exposed ends bonds the face of the wall into a surface which is highly resistant to the cutting action of hot gases and corrosion by slags. No material from an old wall is wasted.

The Schaffer Engineering & Equipment Co. has combined its administrative, sales, and manufacturing departments in its new general offices at 2828 Smallman St., Pittsburgh, Pennsylvania. This arrangement will enable it to render more efficient service to its clients, as the organization will be thoroughly co-ordinated and augmented with additional personnel and facilities. The company's new offices, adjacent to its city factory, have been completed. Removal to the new quarters took place on August 1.

'Volume v. Weight', a new booklet issued by the Hercules Powder Co., presents a phase of the explosive question which the average user very seldom considers. An important point which should not be overlooked is that the bulky explosives, such as Special No. 1 or Hercomite, may show a net saving over costs obtained by using the regular grades of dynamite. Everyone interested in reducing blasting costs should read this booklet. It may be obtained free, by writing to the Advertising Department, Hercules Powder Co., Wilmington, Delaware, or to any branch office of the company.

T. A. RICKARD, . . . Editor

AGITATION plays an important part in flotation; it is essential in many applications of the process. It may be applied indirectly or directly; purposely, or it may result as a concomitant of some phase of pulp conveyance. In the majority of instances it involves expense for power, and careful adjustment; hence the desirability of studying the matter from all angles. On another page of this issue we publish an article on the subject by Mr. Frederick G. Moses, the flotation engineer for the Barrett Company. Mr. Moses' previous connection with the U. S. Bureau of Mines will be recalled, when he made interesting contributions to the technology of graphite and on the influence of colloids in flotation.

DISCUSSION this week includes two letters on the mining law, the first from Mr. L. O. Howard, Dean of the School of Mines and Geology, in the State College of Washington, and the second from Mr. S. A. Knapp, honorably known as a mine operator in California and Nevada. Each treats the subject from a different angle. Mr. M. F. Donahae suggests that a larger use of copper would ensue if the public knew that bronze or brass is cheaper than steel for the making of machinery parts. Mr. Donahae is with the Los Angeles Foundry Company, which, he informs us, "is not in the brass or bronze business". Next comes a thoughtful contribution on the relative merits of electricity and steam as forms of power for use in gold-dredging. This is written by our friend Mr. Leon A. Perret, who is now at Yokohama. An engineer, who desires to remain anonymous, writes on the education of the mining profession. The last letter, from Mr. William Crocker, contains an ingenious suggestion.

METHODS of the ancients, for recovering gold and silver from ores, often formed the foundation on which modern practice rests. Curiosity has been evinced in many quarters as to the customary procedure in Chile and Peru during early times for the recovery of the precious metals, chiefly by amalgamation—a process that is still responsible for the production of more than half of the world's supply of gold. On another page of this issue we reproduce, from a book that was published in London about 100 years ago, an account of the methods of milling and amalgamating that had been evolved by the Indians of those regions. It will be noticed that the operators considered that salt, dung, and warmth were essential to efficient amalgamation. Dung, by the way,

is a *sine qua non* in such countries; it is still used throughout the nitrate *pampa* to aid in the clarification of liquors that contain *borra* or slime; its function is, probably, a mechanical one. The amalgamation process described included a fermenting stage; and a simple method of testing showed them whether the *cuerpo*, or moistened cone of concentrate, salt, and dung, had been properly treated, or whether it should be set aside for more fermenting. In the warm summer days the process took from eight to ten days; in winter, three weeks.

OUR contemporary, the 'Journal of Industrial and Engineering Chemistry', apropos of the recent visit of British and Canadian chemists to New York to attend the joint meeting of the Society of Chemical Industry and the American Chemical Society, affirms, *inter alia*, that "the period just before us is pregnant with possibilities of great good, not so much to ourselves as to the lands we love. It is a time for great things. The occasion is here. Unfetter the imagination. Let us plan for the future on the broadest lines, and unitedly set about to accomplish its fulfillment". Again, "The broad basis of sympathetic understanding in each of these joint meetings now in progress lies not so much in a common language as in the fact that in each of our lands the chemist, before the War, occupied a lowly plane in the body politic. He was considered a man apart, no glamor attached to his accomplishments, his opinions were given but scant attention by men in power". We accept the sentiment, for it applies equally well to the mining engineers. As we pointed out in a recent issue, the English-speaking chemists have shown what can be done in co-ordinating research and advance, and in the avoidance of duplicated effort in technical work; they now set an example of the value of personal contact as a vital factor in sympathetic understanding.

ALTHOUGH the United States has been accumulating gold for a considerable time, it is interesting to note that European governments are not being drained of their reserves of the yellow metal. This fact is emphasized in an analysis of the subject that appears in the current issue of 'Commerce Monthly'. Although over \$250,000,000 in gold was received from Europe during the first six months of this year, nevertheless a slight gain is noticeable in the total gold reserve of central banks and government agents there. Only three of the

14 chief gold-holding countries showed a diminution, slight in the aggregate, in their stocks between January 1 and July 1. The net increase among the 11 countries amounted to only about one million dollars. On the other hand, the gold stock held by the Federal Reserve banks in the United States increased by over \$400,000,000, or by nearly 20% of the amount held on the first day of the year. Two-thirds of this came from Europe, the remainder from non-European and domestic sources. The increments of gold since January 1 are accounted for chiefly by three streams of metal: one of these comes from Africa, by way of London; one from India, also by way of London; and one probably from Russia, through various European countries. The combined totals of gold received from Africa and India during the period under review amounted to \$106,599,000; the exports during the same period amounted to \$136,799,000. It is clear, because of small imports into England other than from Africa and India, and because of small exports other than to the United States, that almost all the gold sent here from England was made up of the equivalent of supplies from Africa and India. In addition, \$17,200,000 was received direct from British India; it has been estimated that no less than \$100,000,000 in Russian gold was imported during the same period. At the outbreak of the War the Russian State Bank held about \$800,000,000 in gold; by the end of 1917 this had been reduced to little more than \$600,000,000; and it is probable that little remains now. Apart from Russia, Europe is about holding her own as far as gold reserves are concerned. The stock in the United States at the beginning of July was estimated at about \$2,461,931,000. Our selling capacity is restricted by the stationary condition of the stock of gold in Europe.

BISBEE, in Arizona, has at least two resources. One is copper, for Bisbee is the centre of the greatest copper-producing district in the South-West—we would say in the world if it were not for the sensitiveness of our friends at Butte. The other, it seems, is climate. Anyone who has spent as much as 24 hours, during the summer, at Phoenix, the capital of Arizona, may demand substantial proof of this assertion. Bisbee is only 150 miles from Phoenix, and that prosperous city is among the five hottest places in the world during a large part of the year. However, it happens that there is a difference of elevation of some 4200 feet in favor of Bisbee, which may account for the ideal climate of that mining centre. Whatever the cause may be, the superiority of Bisbee's 'year-round' climate is vouched for by none other than Mr. A. G. McGregor, resident of Bisbee and known internationally as a designer and builder of smelters. We gather from a speech made by Mr. McGregor before the Warren District Luncheon Club at the Copper Queen hotel that he has turned his talents temporarily to 'industrial engineering', as their profession is styled by the fancy-salaried gentlemen who are showing San Francisco and other cities how to stimulate growth, develop industry, promote civic and municipal

prosperity, and, in general, in newspaper phrase, "launch booster campaigns". Mr. McGregor, as might be expected of a real engineer, is specific in his recommendations. The fact that the copper business, unfortunately, is temporarily comatose is no good reason for sitting with folded hands and waiting for 1922; turn to the other asset and realize on it, says Mr. McGregor. "There is not a place anywhere that has a better year-around climate than we have here; there is not a city in the South-West that is more convenient to the undeveloped resources of southern Arizona and Sonora. I believe, with a little effort on our part, we can materially increase our permanent population of independent citizens and also make summer our most prosperous period, instead of the usual dull season when many of our people go to the coast and spend their savings." He proposes a huge out-door swimming pool to provide the bathing that is afforded by the beaches of California. He urges the improvement of the golf-course at the Country Club and believes that opportunity would be created for bigger and better hotels. He advocates increasing the scope of the Summer School of the State University, which now meets at Bisbee; and he sees advantages in consistent and conservative advertising. It seems that the Warren district is composed of a number of small towns with different names; why not change these to East Bisbee and South Bisbee, and call Osburn, the point from which the branch railway leaves the trans-continental line, by its logical name—Bisbee Junction? Convert the Warren District Commercial Club to the Bisbee Commercial Club, arouse the interest of automobile tourists, and take other measures to make Bisbee known to the world, advises Mr. McGregor, who concludes with this sound observation: "A contented, enthusiastic people in the district will mean much to the mining companies as time goes on. It will mean more employees owning their own homes, better efficiency, the working of lower-grade ore; it will mean more intensive development of our wonderful mining district."

A Worthy Purpose

On October 10 a representative gathering of American engineers will assemble for dinner at the Engineers Club of New York to welcome delegates from the principal engineering societies of Great Britain and France. This event will celebrate the return of the mission of American engineers that went abroad this summer to bestow the John Fritz medal upon Sir Robert Hadfield of London and M. Eugene Schneider of Paris; it will also mark the launching of a movement to promote world-wide unity among the English-speaking peoples and among those who co-operated during the War against Germany. The idea of the movement was born during the War, when British and American engineers shared the perils of the battlefield and worked side by side with the French, particularly at the time when the German armies sought to drive the British under General Haig to the coast and win their way to the Channel ports. It is proposed now to establish a new international contact be-

tween engineers on the two sides of the Atlantic, with a view to promoting concord between English-speaking countries, to advance the art of engineering, and to work along conservative lines for the establishment of international peace. The gathering on October 10 is expected also to mark the recognition of the engineer as a factor in constructive national and international policies as well as in the technical field to which he is particularly devoted. For that reason Mr. Herbert Hoover will be one of the honored guests. Enlightened statesmanship will be represented by Lord Bryce and Mr. Charles E. Hughes. Besides these three exponents of international amity there will be present as guests twelve members of the deputation that went to Europe to bestow the John Fritz medal and representatives of the British and French technical societies whose hospitality they enjoyed while on their mission. It is now proposed to establish "a new international contact which shall promote concord among the English-speaking countries, advance the science of engineering, and work along conservative lines for the establishment of international peace". Never was a more worthy purpose announced; gentlemen, go to it, the profession that you represent so worthily is with you, heart and soul. Such a purpose should find support not only among Americans of colonial stock but among all intelligent and serious-minded citizens. We can imagine that it will make its appeal to German-Americans and others whom it is necessary to describe by means of a hyphen, for the movement is not political nor racial; it is the "peoples" that speak English that are asked to co-operate in furthering goodwill, not for political or economic aggrandizement, but to further the ultimate end of civilization, which is to promote the art of living in peace and plenty. Engineers—especially those devoted to mining—are nomadic persons, they make the whole world their field of action, and as travelers, more particularly in the countries where their own language is spoken, they should serve as excellent missionaries in behalf of a greatly useful idea. In a letter to Sir Robert Hadfield, Mr. Calvin W. Rice said: "We, as professional men, must not only have before us the highest ideals of the engineering profession but we must become internationally minded to the end that the peoples of all nations may be joined in the ennobling concept of a common ideal for all professional men throughout the world. It is not necessary to wait for Leagues of Nations to be consummated, and International Tribunals to be effected, before practising what we preach in regard to peace". Nor need we wait for the Disarmament Conference in order to disarm ourselves of sundry provincial prejudices that stand in the way of such co-operation. Already we have set an example in our relations with our good neighbors, the Canadians. Mining engineers in the East as in the West maintain the most cordial relations with our friends across the one international boundary that has neither fort nor sentry to provoke belligerency. Indeed the only guardians to be found there are those whose business it is to check an excessive fraternization by means of the trans-

fer of the spirituous liquors that are under the embargo of the 18th Amendment. The mining congresses and technical meetings that we share with the Canadians are among the best, in contributions to knowledge no less than in good-fellowship. That unfortified frontier is the best augury of international peace; it is more potent in its suggestiveness than any Hague Tribunal or Paris Conference; it is the symbol of good sense. If two energetic and competitive peoples such as the American and Canadian can live side by side in amity and goodwill, then surely it may be hoped that other nations—all nations—will do the same eventually.

Dr. Ricketts of Arizona

At the time of the Panama-Pacific Exposition in San Francisco six years ago the directors requested that each State should select its most useful citizen for the award of a medal. Louis D. Ricketts was designated the favorite son of Arizona. It was a fair and reasonable selection, for Dr. Ricketts has been identified with the mining industry of Arizona in a very special way. In this issue we publish an interview with him, in the course of which he has been compelled to tell the story of his professional career. We say "compelled" advisedly, for whereas he was willing to play golf with the Editor and even to dine with him, he demurred to an interview until we exercised compulsion. It was done in this way. When he declined the honor, as we deemed it to be, we asked him if in the course of his career he had not been assisted, from time to time, by capable and loyal younger men. "Yes, indeed", he replied. "Then", we retorted, "here is your chance to say so in print, where the acknowledgment means something." That settled it. "You have me." The interview was started forthwith. We commend it to our readers as the story of a remarkable career. Dr. Ricketts—for the prefix has clung to him all these years—had the misfortune of losing his father prematurely, but his mother was an exceptional woman, and enabled him to make a good start. To her tenacity and courage, under adverse conditions, he owed his education. Then, in the nick of time, came the fellowship at Princeton that gave him a special knowledge of economic geology and his doctorate in science. The benefactor who founded the fellowship deserves kindly mention, which it is the more pleasant to make because many of us knew W. S. Ward either at Leadville or at Denver, where he was engaged first in mining and then in real-estate speculation. He himself had taken a post-graduate course at Oxford, and in turn, when he had made a little money, used some of it to create opportunities for the younger Princeton alumni by founding the fellowship. He passed the torch; let that be his epitaph. Our subject started his active career as a surveyor at Leadville and then became geologist to the Territory and State of Wyoming. The critical event of his younger years was the contact with Dr. Douglas. How wide has been the influence of James Douglas and how many are the men eager to acknowledge their debt to him! His memory is

kept warm by the kind deeds he did to his juniors in the profession. To Dr. Ricketts the acquaintance and later the friendship with Douglas meant the opening of the doors of opportunity and the stimulating association with a big man. Before, however, he got into his stride, as it were, Dr. Ricketts went through the experience of losing money in a mine and of becoming 'broke'. That was a useful experience, for it gave him a keen appreciation of the part that money plays in the winning of ore, and inoculated him with the basic concept that mining is only digging unless done at a profit. The contact with the Guggenheims at the Pilares mine is interesting. Evidently at that time the Swiss-American captains of industry now so prominent in mining and smelting were timid of engaging in copper mining, in which since they have scored so successfully. At the Pilares, Dr. Ricketts built his first concentrator and first smelter. That was 25 years ago. Many are the mills and smelters that he has designed and constructed since then. Indeed his later life is crowded with achievements of this kind. He has been an extremely busy man. A veteran engineer remarked to us a few days ago: "Ricketts was as hard a worker as Hamilton Smith and worked in just that nervous way, not wasting a minute, day and night—early in the day and late at night". This association of names is appropriate; Hamilton Smith is only a name to the younger generation, but he was the undoubted leader of the mining profession forty years ago. That reminds us that our interlocutor had a copy of 'The Ores of Leadville and their mode of occurrence as illustrated in the Morning and Evening Star mines, by Louis D. Ricketts, B. S., Ward Fellow in Economic Geology of the College of New Jersey, Princeton, 1883'. That was the thesis by which he won his D.Sc. The newness of much of our engineering practice is suggested by the references to the introduction of belt-conveyors in mills and to the use of structural steel; likewise the adoption of gas-producers for generating power. In connection therewith, Dr. Ricketts had a chance to do honor to John Langton, and he availed himself of it gladly, as in his acknowledgments to Thomas Robins, H. A. Fitch, James S. Douglas, H. Kenyon Burch, Charles S. Shelby, Thomas H. O'Brien, Horton Jones, David Cole, W. D. Thornton, John C. Greenway, C. H. Repath, A. G. McGregor, Charles E. Mills, L. R. Wallace, L. O. Howard, James A. Potter, and Henry A. Tobelmann. It is a gallant company, of whose assistance and fellowship any man might be proud. After all, the choice of men is the larger part of generalship, and in this phase of his more important operations in the field Dr. Ricketts has shown a sagacity of no common order. And if a sagacious man works earnestly, he is likely to succeed. All he needs besides is opportunity and health. The latter Dr. Ricketts had in relatively small measure, for he has often taxed his physical strength unduly, but the wiry frame and the nerve of the hardy stock from which he sprang has stood him in good stead. As for opportunities, they were plentiful in the early days of Arizona and in the later days of big copper enterprises. He was ready for them.

He had the qualities to make the most of them. One of the qualities was a mind open to new ideas, willing to accept right suggestions, not unwilling to abandon a pet theory if it were disproved or to discard a favorite method if a better were forthcoming. A willingness to give credit to whom it was due stimulated the co-operation of his staff. From them we learn that once he has given a job to a man he lets him alone; he shows confidence by not worrying him; he does not interfere except when it is a part of his duty to do so. Under such conditions, as one of them has told us, there remains "nothing to worry about except the possibility of not proving worthy of that kind of confidence". The record of his varied achievements, covering notable accomplishments in geology, mining, milling, smelting, and other allied branches of engineering, bespeaks a flexible and comprehensive mind, able to make a scientific study of a fresh subject and to apply that study to economic purpose. Another characteristic, essentially scientific, is his refusal to take anything for granted, where doubt exists, in a technical matter. Before he commits himself to a plan of action involving large sums of money, he avails himself of expert advice from the outside. He is not cocksure, but deliberate. That is why he became so successful as a consulting engineer to some of the largest companies operating in the South-West. And with it all he has a sense of humor. William C. Greene, the Colonel of Cananea fame, was persuaded to bore for oil near the copper mines in Sonora, and when he failed to strike oil-sand he asked Dr. Ricketts to advise him where to sink his next well. The answer came promptly: "In Pennsylvania". His friends tell us that—until he was married—he was "not much on clothes". Indeed, there is a story of his having been rebuffed by a Pullman porter, who mistook him for a tramp. Also—until he was married—he was so immersed in his work that he looked upon the wedded state as interfering seriously with more important things. When a chauffeur whom he employed at Cananea disappeared for a few days, he was overheard to say: "I guess he has gotten in some serious trouble. I suspect it's marriage." However that prejudice of the Doctor's was cured in due time, completely. Among other honors that have befallen him we may mention the presidency of the American Institute of Mining Engineers, in 1916, and the award of a gold medal by the Institution of Mining and Metallurgy, in London, for his paper on 'Experiments in reverberatory practice at Cananea, Mexico'. During the last two or three years he has been trying to retire from active work, but his semi-retirement looks a good deal like an average man's busy season. Whenever he does withdraw from the stress of professional work he can do so with a keen realization of much done and supremely well done, of having fulfilled to the hilt the definition of an engineer as one who has learned "the art of directing the great sources of power in Nature for the use and convenience of Man", and, more particularly, of enlisting the hearty co-operation of other men in winning metals for the needs of our material civilization.

DISCUSSION

Revision of the Mining Law

The Editor:

Sir—It seems to me fairly evident that in revising the mining laws we have the interests of another eternal triangle to consider. This triangle is made up of prospector, capitalist, and engineer, technician, or operator. The interests of these three groups, while identical in many respects, may become divergent when considered on too narrow a basis, as appears to be the case in much of the discussion that has appeared in your columns.

Obviously eminent engineers composed the commission that prepared the draft of the proposed revision. A certain chain of events leads to this position of eminence and may result in a viewpoint widely and innocently divergent from that of the prospector. The more widely an engineer practices successfully, the more eminent he becomes, the less he has to do with prospectors and the more with capital. There is a tendency for his point of view to become progressively that of the large operator, or large company, which may be called the capitalist angle of the triangle. He is in close touch with the losses due to apex litigation, and in reaction against this is prone to allow the pendulum to swing too far in the opposite direction, and in trying to relieve operators of their onerous burden, he may in perfect good faith inadvertently add to the burden of the prospector.

On the other hand, the prospector is rarely concerned with apex suits, and views the revision from his viewpoint only. Discussion so far seems to have come from these two angles. As my present occupation has to do directly with neither prospector nor capitalist, possibly I may be conceded to have a viewpoint that is at neither extreme, and to be able to look at the question judicially in its bearing upon the mining business as a whole. Standing in the centre of the triangle it would appear to me extremely desirable to so modify our mining laws that the difficulties of applying the law of the apex may be eliminated, at least as to future locations, and as to re-locations of claims now held. We are all aware of the vast number of claims that are annually re-located in lieu of assessment work, so it may be granted that, after all, the new law would in course of time apply to a sufficient number of locations to make the reform worth while. While gaining this desirable end let us not add to the burden of the prospector. Vertical boundaries to avoid apex disputes, large square locations to ensure adequate ground in case the vein proves to have a course widely divergent from that assumed at the time of location, elimination of location by cardinal points to obviate the

endless difficulties of tracing old lines, often inaccurately run, would, I feel, accomplish the desired end. There would be some overlapping of claims, of course, but this would not be a serious objection, because the overlap would be in one plane only, and not in three, as under the apex law.

The discovery required may well be modified so that a claim may be held for a long enough time without discovery as will ensure diligent effort to find mineral. Surely if mineral sufficient to constitute discovery cannot be found within five years, the locator might with justice be compelled to forfeit his claim. Certainly no money payments after that date should be permitted to tie up claims indefinitely without discovery. By such an absolute limit to possession without discovery, the capitalist would not be favored at the expense of the prospector.

Most assessment work is known to be virtually useless. The law might, perhaps with difficulty, be amended to secure more bona-fide and effective assessment work. By no means should the payment of cash in lieu of assessment work be permitted. Many substantial reasons have been given in previous discussion and need not be repeated here.

Mr. Sheldon's recent comments concerning the need of permanent monuments are pertinent, and any engineer accustomed to examining prospects will be inclined to agree with him.

My excuse for occupying so much space in your valuable columns may be found in a desire to contribute something that should be free from the bias that has been too frequently evident in the recent discussion of the revision of the mining law.

L. O. HOWARD.

Pullman, Washington, September 12.

The Editor:

Sir—An examination of the text of the proposed new mining law indicates a radical departure from some of the basic principles of the present law. They seem to me to be unwise, both from the standpoint of the miner and of the Government.

The purpose of the law is, or should be, to secure the exploration and development of the mineral areas, and to do this, every encouragement should be given the prospector and miner that is legitimate, with as little hampering red tape as possible; and it should be recognized as well that the prospector is probably as honest as the Government appointees.

The search in the field by the prospector is what leads to the finding of new ore deposits—not sitting in an office,

and drawing checks in favor of the Government in lieu of such work, which method leads to tying up large areas without active development work.

To summarize briefly, I offer a few suggestions:

(1) Annual assessment work of \$5 per acre should be required, and performed (and not payment to the Government in lieu of same).

(2) Claims should be allowed to be staked without discovery, providing that in such cases work shall be commenced on such claim, say, within 60 days after location, and a shaft at least 5 ft. by 5 ft. square sunk at least 20 ft., or its equivalent, if done by tunnel, before the expiration of 120 days; this work to count as the assessment work for the first full year, and fraction of year, in which the claim is located.

(3) The affidavit of the locator, with one reputable witness as to discovery, should be sufficient. The prospector should not be compelled to pay the expense of a U. S. Deputy Mineral Surveyor to examine and verify same.

(4) It should not be compulsory to patent claims within seven years. The prospector may not have the means to do this, but, by his own labor, may be able to keep up his assessment work in the nature of development work on his property.

(5) Discovery should be specifically set forth, to be (in the language of one of our most competent judges, who was a miner himself) "such a discovery of mineral as will warrant the expenditure of labor and money in its development by the discoverer".

(6) In case of location of a claim, with an actual discovery, a 10-ft. shaft, 5 ft. by 5 ft., should be sunk (or its equivalent in cut or tunnel), within six months from date of location at said discovery point, to be counted as part of the assessment work.

(7) Locations should conform as near as possible to the lines of Government survey. The prospector in locating cannot be expected to be a surveyor, and until his location is perfected, he may not wish to disclose his discovery to others.

Copper

The Editor:

Sir—It seems to me that there should be some remedy for the diseased condition of the price of copper besides 'supply and demand'. It is unreasonable that a public necessity, on which depends the prosperity of the West and to a great extent of the nation, should sell at less than the cost of production, especially when that cost has been reduced to a minimum through the application of every possible device for saving material and labor, the use of modern machinery of enormous capacity, operated at a degree of efficiency probably unequaled in any other industry.

Of course, when the copper surplus has been depleted, the price will advance naturally, but in the meantime how many clean and wholesome copper prospects and

projects will be reported in the issues of 'The Copper Handbook' as 'dead'? Must we sit back and watch the industry suffer? We know that the largest producers are safely entrenched financially and can weather a long hard slump, but at what cost to the public?

Mr. J. L. Harmon, in his letter to you, opens a way for all of us to assist in a small way, in disposing of the accumulated copper. It would appear that the daily press of the country would be sufficiently interested to take the question up, as there is much that can be written that will interest the general public.

At the present price of copper, solid copper utensils of all kinds can be produced at a cost lower than many inferior materials having short life; they could be sold in competition with the inferior articles and if the public was advised of the value of these copper utensils, there would be a demand.

There are many small parts of machinery used in every line of endeavor that can be manufactured of brass. Today these parts can be cast of brass at a lower cost for the finished article than if made of steel—almost as cheap as if made of cast-iron.

When we are given patterns or drawings with a request for estimates on cast-steel parts, if in our opinion the parts will prove as economical if made of bronze or brass and will answer the same purpose, we offer the suggestion or make the recommendation that brass or bronze be used. If all manufacturers of machinery will do this, we believe that it will, at least in a small way, assist in disposing of the copper surplus.

M. F. DONAHUE.

Electricity v. Steam in Gold-Dredging

The Editor:

Sir—In criticizing my conclusions regarding the inadequacy of installing electric dredges on the Kolehau mines of the Orsk Goldfields, Ltd.; Mr. G. L. Holmes, in his letter published in your issue of April 30, rather side-steps the question. At the outset I wish to emphasize that nowhere in the course of my article did I argue against the use of electrically-driven dredges, and I had no intention to comment on the relative merits and advantages of steam-dredges as compared with electric ones. As clearly stated, my remark relates to the one particular case mentioned on the Kolehau mines, but as Mr. Holmes seems to advocate the installation of electric dredges in all cases, and under all circumstances without exception, may I be permitted to analyze his arguments.

On all well-designed steam-dredges the entire machinery—boilers, engines winches, etc.—is placed alongside and forward of the main gantry, leaving the whole deck aft of it free for the washing apparatus, just as is the case with electric dredges; and on account of this it is just as easy to place adequate gold-saving appliances on a steam-dredge as on an electric one. On the latter the fore part of the deck is clear, but it is of no use for the saving of the gold. Reduction of space for the gold-saving devices on dredges depends on the disposition of the

machinery, and is not necessarily a consequence of the use of steam as driving power.

Boilers economical in the consumption of fuel may be used on dredges, as, for example, boilers of the locomobile type with superheated steam (system R. Wolff, Buckau-Magdeburg), which may be considered as economical as any stationary boiler in a generating plant. The type of main engine and winches used on dredges may not be quite as economical in the use of steam as the stationary engines of a power-generating plant, but, on the other hand, to convert steam-power into electric current and again transform this latter into mechanical power is not an economical process; and then there is power lost in the line. All these losses have to be compensated by an extra consumption of fuel at the electric-generating plant, and I venture to state that all in all the application of steam direct on the dredge is more economical than by means of an electric-power plant on shore.

The escape of vapor from leaky pipes, to the action of which Mr. Holmes ascribes so prejudicial an effect, cannot be considered a serious factor, especially since wooden hulls are almost entirely abandoned. If there is an escape of steam from leaky pipe-connections it is a proof that the man in charge of the piping has not done his work conscientiously. On the Schouvaloff dredges, on which the whole machinery, the digging apparatus and washing appliances, was enclosed in a housing, and operations were carried on until the beginning of winter, sometimes even until the end of December, when the temperature was from 15° to 20° R. below zero, there has never in the course of ten operating seasons been a noticeable escape of steam from the pipes.

The conveying of wood-fuel on board the dredge is not so arduous a task as Mr. Holmes thinks, being greatly facilitated when piling the wood alongside and close to the lateral boundary lines of the area to be worked in accord with the advance of the dredge. This is an easy thing to do everywhere in Russia, the Kolchan mines included, as the haulage of wood-fuel is always done by sleigh at the beginning of the winter before the heavy snowfall, and therefore does not require the construction of any roads. With an electric-generating plant using wood-fuel supplied from the surrounding forest no permanent haulage-road can be constructed, as Mr. Holmes suggests, because the haulage is constantly changing as the felling of the wood progresses.

The handling and firing of fuel is the same in both cases, with electric as well as with steam-dredges, as it requires the same amount of labor (one man per shift) to haul the fuel from the stacks to the boiler-house as from the banks of the pond to the dredge. Thus, when using wood-fuel, a steam-dredge and an electric one are exactly under the same conditions as far as haulage and firing are concerned. As for the dirt, I think it is easier to sweep it overboard than to shovel it and carry it away from the boiler-house. There is one feature decidedly in favor of the steam-dredge that is of special importance in cold climates, consequently for the whole of Russia

and Siberia, and that is the heating, which on a steam-dredge is gratis, whereas on an electric dredge special boilers or stoves have to be installed, and above the extra expense the task of conveying fuel on board the dredge cannot be avoided, at least during part of the operating season.

Mr. Holmes says, "The life of the electric dredge (accidents excepted) will be 50% longer than that of a steam-dredge, that it will handle a minimum of 33 $\frac{1}{3}$ % more material than the steam-dredge, will be 100% more economically efficient". On what calculations are these statements based? They appear unfounded. The life of a dredge depends mainly, if not exclusively, on the strain to which the digging apparatus is subjected, and this is in direct relation to the nature of the ground worked quite independently of the mode of generating power for breaking up the ground. It is beyond contradiction that the same dredge dealing with loose sand, or working in easy ground, will have a much longer life than working in hard ground, such as cemented gravel containing large boulders, or breaking up tough and hard bedrock. Given two dredges of equal bucket-capacity, working the same ground under otherwise the same conditions, the yardage will depend on the power driving the bucket-line, that is, on the number of horse-powers applied to the shaft of the upper tumbler. Whether these horse-powers applied are developed by steam or by electricity makes no difference, especially when the usual mode of transmission of power by belting is used in both cases. Therefore, from a technical point of view, I see no plausible reason why an electric dredge should handle more material than an equally powerful steam-dredge of the same size working in other respects under identical conditions. Why just a minimum of 33 $\frac{1}{3}$ % in favor of electricity, and not 20 or 50%? What is the criterion? As far as economic efficiency is concerned it is a matter of consideration in each individual case, except, naturally, in those comparatively few instances where electricity can be generated by cheap water-power.

The case of the Conrey Placer Mining Co.'s dredges is not persuasive. Was it solely the substitution of one driving power for the other that converted a losing enterprise into a profitable one? If so, it only shows that in this particular instance, on account of local conditions, the generating of electric power by steam proved cheaper than the direct use of steam, but, I believe, there is far better reason to ascribe the favorable results to the fact that the ground had been worked before, and thus formed a loose disintegrated material, so that a considerably greater yardage and better saving of the gold were obtained. It is a fact known to every gold miner that ground re-worked even by the original method nearly always yields some profit, and it appears to me beyond doubt that if the Ruby placers had been re-worked even by the same old steam-dredges, some profit would have been made, if not so large as obtained by the installation of modern improved dredges. The main factor of success was that the new electric dredges were of modern construction, and certainly all the experience gained during

the operation of the old steam-dredges was taken advantage of in designing the new ones, first of all in regard to the gold-saving appliances. Mr. Holmes does not state if the new electric dredges had buckets of greater capacity than the old ones, but this is likely to be the case, because in the early period of dredging, before 1906, buckets of 7.5 or 9.5 cu. ft. capacity were not in use in close-connected bucket-lines, as far as I know. All this goes to show that the performance of the old steam-dredges and that of the modern electric ones, which replaced the former, is not comparable from an economical point of view. I venture to say that if the old steam-dredges had been replaced by modern steam ones, better built and better designed with adequate gold-saving tables, which, as said, can be placed in a perfectly satisfactory manner on steam-driven dredges, the result would have been much the same as with the electric dredges.

At present there are three kinds of driving machinery on dredges: electric, steam, and oil engines. The last type has been hitherto used for operating small dredges only, but if authorities in naval construction are thinking of supplanting steam by oil on dreadnoughts it is almost certain that in the near future this engine will be applied to large dredges also. Each of these three types of driving machinery has its own field and will prove the best suitable in certain individual cases according to the set of conditions under which the particular dredge has to operate. I am aware of the advantages of the electric dredge, but these advantages do not, under all circumstances, outweigh the positive features of the steam-dredge. I fully believe that electricity on the Conrey dredges was the most suitable driving power to use, the more so that the electric installation supplies four dredges, but Mr. Holmes' statements do not alter my opinion that the use of electricity for driving one dredge only* on the Kolchan mines, or the placing of the generating plant 15 miles away when there is plenty of the same kind of fuel close to the working area, is an exaggeration in engineering, from the economical as well as from a technical point of view, which cannot find its justification in any plausible reason.

L. A. PERRET.

Yokohama, July 21.

Education of Engineers

The Editor:

Sir—I have just noticed some excellent remarks on the above subject in a letter by Mr. Augustus Locke, which appeared in the issue of April 16. Among other things, Mr. Locke stated that, "A few simply stated precepts—such as that of William James: 'Seize the very first opportunity to act on any resolution you make . . . '—learned thoroughly and incorporated in the character by practice, might be more valuable than an average university education. It is conceivable that we will some time have important schools that will undertake to teach

nothing else". Let us hope that this may be so, for they would certainly teach something that need never be forgotten—something that would be of inestimable value throughout life.

The advice of William James, stated in simpler language, is, 'Do it now'; and no more valid reason for success in life was ever advanced than a profession of adherence to this simple rule. The unprogressive nations of the world are those which, as aggregations and as individuals, never do today what can possibly be put off until tomorrow; among the private individuals in any nation the failures are always to be found among those who procrastinate. It is not an easy matter to act up to the simple advice contained in so hackneyed a phrase; yet I believe with Mr. Locke that if we learned to respect the vital importance of prompt action, as soon as a good resolution was made and when our duty was clear; if we realized the cumulative ill-effects of unpunctuality, postponement, and delay, we could dispense with much of the useless facts and figures with which we clutter our heads when in school and college. Instead we would be in a position to discriminate between the worth-while and the valueless, between the trivial and the important, between the productive and the useless; and we could do this at a time when our training had taught us to 'do it now'.

More can be achieved by the exercise of an acquisitiveness for the information that we know is valuable, than otherwise would result by the reception of the miscellaneous facts, figures, and other data, the memorizing of which constitutes the modern idea of education. The failure of so many machine-made graduates is due to the entire absence of facility in the exercise of good mental habits, when the big problems of life have to be tackled. It would be interesting to learn how many successful men owe their present position, not to what they learned at college or at school, but to the recognition of the importance of fundamental principles of discernment between what is true and what is false, coupled with an encouraged acquisitiveness for what is valuable and useful.

San Francisco, September 7.

Flotation and Lubrication

The Editor:

Sir—Some time ago an old sailer told me that the bottom of a racing yacht was first painted, then tallowed in order to make it slip faster through the water. Wouldn't oiling the bottom of a vessel have the same effect as tallowing the bottom of a yacht? The oil could be forced through small holes in the bottom. But how make the oil stick to the sides? Here, it seems to me, is where the flotation engineer might apply his science. It strikes me there are great possibilities in the way of saving time and fuel by lubricating the sides of a vessel with oil.

WM. CROCKER.

Prescott, Arizona, September 17.

*According to latest information given in Mr. Speak's letter published in 'M. & S. P.' of June 18, 1921.

ORE-CONVEYOR IN THE NEW CORNELIA MILL

Louis Davidson Ricketts, of Arizona

An Interview. By T. A. Rickard

Dr. Ricketts, you are a New Englander by birth?

No; I am a Marylander. I was born at Elkton, in Cecil county, Maryland, in December 1859.

Were your people interested in mining in any way?

My father was the owner and editor of a country newspaper, and his family had been farmers in Cecil county since the 17th century. My mother was the daughter of a Scotch-Irish school-teacher, from the University of Belfast; he came over to this country with his wife and conducted a private school. My father died a few months after I was born. My mother had four children and made up her mind she was going to educate them. She was in the South, the war came on, and she had to wait five years to settle up my father's estate. Then she moved up to Princeton and gave all of her children a higher education, for the time being at great personal sacrifice.

You went through the public schools and then to Princeton?

No; I had a defect of the eyes when I was born and did not learn to read until I was ten, so I received my preliminary education in private schools. You know our public-school system was not much to boast of in those days. I entered the John C. Green School of Science, in the College of New Jersey, now known as Princeton University.

When did you graduate?

I graduated in 1881, was awarded a fellowship in chemistry, and spent the following year in post-graduate study.

In chemistry?

Yes, in chemistry. About that time, Dr. McCosh, president of Princeton, had made a tour of the West and met a Princeton man named W. S. Ward, of Leadville. Ward offered a competitive fellowship in economic geology open to post-graduates. I was awarded this fellowship and went out to Leadville, in accordance with the terms of the fellowship, to study mining geology.

At that time Leadville was booming, was it not?

Leadville was in its glory, although there were really no very large individual mines, as measured by later standards; it consisted of a number of large ore deposits chopped up into small holdings. After I had completed my studies at Leadville, which lasted four or five months, I returned to Princeton in the fall of 1882, wrote my thesis on the ores of Leadville, for a doctorate, and was granted a degree of D.Sc., 'in course', at Princeton.

What does "in course" mean?

It means that you take the degree as a result of examination after two years of post-graduate study; it is not an honorary degree.

How did you pass from chemistry to mining?

While I was trained as a chemist, I had had a little experience in surveying. At the end of my post-graduate course, I was offered the choice between teaching at Princeton and going to work as a surveyor for the Morning and Evening Star mines, which were under the management of Mr. Ward, and I remember particularly the advice that was given to me by my dear friend, Professor Henry B. Cornwall of Princeton. He told

me that, although he would be glad to have me as his assistant, he knew that there were great mountain systems in the West, that Gilpin county had been developed, and that now Leadville had come, and that he thought there surely would be a great development of mines in the mountains of the West, and he believed that, if he were I, he would take the chances and go out and grow up with the West.

He must have been a man of some imagination?

I should hardly say that; he had wonderful common sense.

When did you go to Leadville as surveyor?

I went there in July 1883, and remained as surveyor of the Morning and Evening Star mines until the spring of 1885. At that time I was given the opportunity to go to Silverton, to take charge of the development of some mining claims on Galena mountain and in Poughkeepsie gulch. They were owned by the Gipsy Maid Mining Co. of New York City. Slight development showed that these prospects were valueless, so, in the fall of 1886, I recommended that they be closed-down, and was out of a job.

I remember meeting you at the Morning Star mine at Leadville in the fall of '86, so I presume you returned to Leadville.

Yes, I returned to Leadville and entered into general practice as a surveyor and remained there until the spring of 1887, when I was offered the position of Geologist of Wyoming, which I accepted.

How did it happen that you were offered this appointment?

Wyoming was then a Territory, and President Cleveland had appointed Thomas Moonlight, of Kansas, as Governor. The position of Geologist of the Territory was vacant, and he, not being a mining man, requested the Governor of Colorado to recommend a man.

Was Alva Adams the Governor of Colorado at that time?

Yes; Governor Adams referred the matter to Fred Buckley, of Leadville, who recommended me for the position.

You liked your work in Wyoming?

Yes, I liked it very much. I was inexperienced and was really not much of a geologist, but I liked mining and kindred subjects, and I not only worked officially and published various reports, but I was also encouraged to, and did, take outside consulting work within Wyoming, and during my time there had experience in railroad reconnaissance work for the Union Pacific and Burlington railroads.

How long did you remain there?

In 1889, I think it was, Wyoming became a State, and Francis E. Warren was elected governor. He is now U. S. Senator. He re-appointed me as Geologist, and I remained until the fall of 1890, when I resigned to take a position in the South-West with Dr. James Douglas.

How did you first meet Douglas?

In the summer of 1881 I joined a college friend in surveying his father's country place on the Hudson river. Eight years afterward, my friend and his father recommended me to William E. Dodge as a capable young man, and Mr. Dodge spoke of me to Dr. Douglas, who sent for me and, after taking me on a trip to Arizona, employed me as an examining engineer. That was in the fall of 1890. I spent some time in studying the coalfields of northern Sonora and those on the Apache Indian reservation in Gila county, Arizona. These coalfields were worthless, but Dr. Douglas was very anxious to find coal and sent me back repeatedly to examine them. I remember that he told me that the transmission of electric power was going to become vastly important, and that if I could find even an inferior grade of coal that would burn at the pit he believed that we should acquire it, because, with the development of electric transmission, it would be of great service to the Arizona mines, on account of the great distance that coal had to be hauled to the South-West. At that time Dr. Douglas had purchased the Copper Basin mines, near Prescott, and was installing a small leaching-plant to test the Hunt and Douglas process. For about a year I was in charge of this enterprise. The process was sound theoretically, but metallurgically it was a failure, owing to the mechanical imperfections of the plant and the volatilization losses. Apparently, oxy-chlorides were formed in large quantities, which could not be removed by washing, and caused great loss by volatilization when the impure sub-oxide of copper was smelted.

What did you do next?

About the close of 1892 I left Dr. Douglas and worked on my own behalf in Colorado and Wyoming as a consulting engineer. I also mined on my own account in the Silverton district, making trips to the South-West for Dr. Douglas at intervals. At Silverton I obtained the most valuable experience of my life. I took a lease, jointly with friends, on the Sierra Madre mine on Galena mountain. We struck a pocket of 10-oz. gold ore and made a little money. This gave us courage to put up a mill before the mine was sufficiently developed. The result was that in 1895 I 'went broke' and had to borrow money to pay my debts. What seemed then a disaster proved to be a blessing, because it taught me two things: first, that it is necessary to develop a property before capital expenditures are made for a plant; second, that it is unwise to try to operate a low-grade mine without sufficient capital.

So the rich pocket happened to be—

It proved to be superficial, and the larger bodies of lower-grade ore that we relied upon were likewise superficial.

You will agree with me, Dr. Ricketts, probably, that a little experience in leasing is an excellent experience for a young engineer, by teaching him the fact that the purpose of mining is to make money; in other

words, it brings him face to face with the economics of the industry.

Yes. In those days, I think, it was advisable that a young man should either lease or otherwise go into min-

to go to work underground? As you know, there has always been a question as to whether educated young men should begin their careers by doing manual work.

THE SMELTER OF THE CANANEA CONSOLIDATED COPPER COMPANY, IN SONORA, MEXICO

ing on his own account, in order to gain a concrete idea of the responsibility of mining, and the same thing, I

I think that depends very much upon the individual. Manual work gives him an opportunity to know the

THE CANANEA CONCENTRATOR

think, holds good today, except that there are not as many opportunities for leasing and mining in a small way.

Then would you expect a graduate from a mining-school

viewpoint of the workman; and, if in the future he is called upon to handle men, such an experience is immensely valuable to him. This is merely an opinion, because I have not worked either as a miner or a smelter-

hand; but I have always regretted that I did not have a little experience of the kind, in order that I might be closer to the worker's viewpoint.

You were saying that your mining near Silverton left you 'broke'. How did you extricate yourself?

Dr. Douglas employed me as his assistant. I went to work for him in the previous winter of 1895. That winter I took a pack-train and made an extensive investigation of the resources of northern Sonora. Among other places, I went to Nacozari. At that time the Guggenheims had bonded the Fortuna and Pilares mines, and were doing development work. They were operating a small silver-mill that had nothing but a crusher, rolls, and jigs, and they were packing concentrating ore from the Pilares six miles down the mountain, treating it at this mill, and roasting the concentrate in a Pearce turret-roaster, using oak as fuel. The calcine was then briquetted and smelted to a matte in a 36-in. water-jacketed furnace. The smelter was running intermittently, of course; the ore that they were mining contained about 6% copper; and the smelter was 90 miles from a railway, so I assumed that the work was being done in order to obtain information for a proper metallurgical plant. It transpired, I believe, that the owners expected to profit from the operation, and when they met with a decided loss they became discouraged. I was tremendously impressed with the Pilares mine and thought it a great property, so, when later the Guggenheims represented to Dr. Douglas that they were not copper miners and offered to turn the property over to him if he would assume the bonded debt, which was small, and pay them a very reasonable compensation in case he developed the property successfully. I advised him to make the deal. Dr. Douglas himself visited the property in the fall of 1896 and purchased it for himself and his associates of Phelps, Dodge & Company.

So you became the godfather of Nacozari?

Yes. I succeeded Mr. Danforth as general manager, developed the mine, designed and built a concentrator and smelter. At the same time I designed and built a 400-ton concentrator, a large mill in those days, for the Detroit Copper Mining Co., the financial interest in which was purchased by Phelps, Dodge & Company in 1897. In designing this mill I met Thomas Robins, who had but recently formed the Robins Belt Conveying Co., and as a result I installed one of his 36-in. and two of his 18-in. belt-conveyors at Morenci. This installation, as far as I know, was the first of its kind in the Rocky Mountain region. At this time, in 1897 or '98, I forget which, I made a trip through the North-West to study milling practice. At Salt Lake City I met L. S. Gillette, who founded the Minneapolis Structural Steel Co., and he convinced me of the superiority of steel over wood construction for mills and smelters. As a result of this conference, I introduced all-steel construction in the South-West. Since that date I have directed work consuming many tens of thousands of tons of structural steel. H. A. Fitch, a young designing engineer and salesman in the employ of Gillette, began to come to the South-West a few

years afterward. He aided me greatly in designing and made many valuable suggestions. We became warm friends and later in 1906 we became associated in the structural-steel business, which he wished to enter. While I knew nothing of the business, I knew the man. He has become highly successful after a long and hard pull.

In the construction of the Nacozari plant, my old friend, John Langton, designed the transmission machinery and the power-plant, and supervised its construction. This plant was novel in that it consisted of seven 250-hp. Crossley gas-engines, belted to d.-c. generators, the motive power for the smelter and concentrator machinery being furnished from this central plant. Mr. Langton installed a gas-producing plant of two Loomis-Pettibone producers. At that time Nacozari was 90 miles from a railroad, and as there was abundant oak in the vicinity, Mr. Langton was of the opinion that he could generate a producer-gas from wood, which was done successfully for several years.

Langton died recently, did he not?

Yes, Langton died of pneumonia, in February 1920, at Inspiration. He was a man of splendid personality. He had a tremendous fund of general information, was a good critic of books and plays, and had a profound knowledge of the theory of his profession, and as a consulting mechanical engineer, especially on power and the transmission of power, he did splendid and valuable work. As a mechanical engineer he was identified with the development of the great copper industry of the South-West.

Returning to Nacozari, did you remain there long?

As the Nacozari mines developed, it became evident that a railroad was abundantly justified, and the railroad was completed, though not as soon as I advocated. After the plant had been completed and the success of the mine demonstrated, I was transferred by Dr. Douglas to other work, and was succeeded by his son, James S. Douglas, who managed the property for a number of years very successfully. When the railroad was completed to Nacozari, the steam-turbine had been sufficiently developed, and coal was then obtainable as fuel, whereupon Langton designed a turbine-plant replacing the Crossley engines, which had become antiquated. This was one of the first turbine-plants in the West, I think. At the same time H. Kenyon Burch designed a much larger concentrator to meet the requirements of the mine; this was constructed under the supervision of Mr. Douglas. In the meantime, a reduction works had been built by the Copper Queen company at Douglas, the Nacozari smelter was abandoned, and the concentrate shipped to Douglas for treatment. The Nacozari property continues to be a great producer and has proved enormously valuable.

What was your next task after you left Nacozari?

I took a rest and went to Europe. On my return I was sent to Globe. In 1890 and succeeding years, Dr. Douglas had acquired the Old Buffalo mine, the Hoosier property, and other claims at Globe, which were brought together

under the name of the United Globe Mines. The development work on these claims, for the time being, was dis-

ship of Charles S. Smith. The possibilities of this great mine had not been recognized. It had been worked ex-

THE INSPIRATION MINE

appointing, and for several years the work there was more or less quiescent. In the meantime, the Old Dominion

elusively for high-grade ore; the low-grade material had not received attention, nor had the mine, which had de-

THE INSPIRATION MILL AND THE INTERNATIONAL SMELTER, AT MIAMI, ARIZONA

mine had been acquired by the Lewisohn-Bigelow interests, and after a somewhat varied career the control was taken over by a group of stockholders under the leader-

veloped large quantities of water, been equipped with the proper machinery. As a consequence, the company was nearly bankrupt. In 1903 a consolidation was effected

between the Old Dominion and the United Globe mines, through which the then Phelps Dodge interests assumed control. I was put in charge as manager, and completed the construction work that had already been started by the Old Dominion company under the supervision of Frederic W. Hoar. During the three years following my assumption of the management, I designed and built a concentrator and completed the smelter, but the main task was to re-open the mine. For years the workings had followed the main fault-fractures along which the ore deposits occurred; here the ground was soft and the openings could not be maintained; the foot-wall of the ore deposit, however, which was of diorite, was firm and solid, and an entire new set of workings had to be opened up in the foot-wall country on the six active levels in order to eliminate prohibitive maintenance costs and to avoid ruinous delays. The ore-bearing ground was attacked through numerous short cross-cuts.

Did you have any metallurgical problem?

Yes, several important problems. When I assumed control of the Old Dominion a young man who had worked at Aguas Calientes for the Guggenheims was the metallurgist; and this was my first meeting with Charles S. Shelby. In the years that followed I was associated with him intimately. Shelby was somewhat of a dreamer, but had a wonderfully suggestive mind, and was, I believe, one of our metallurgical geniuses. As often happens, his mind was so active in suggestion that it was difficult for him to separate the commercially feasible plans from the impracticable ones. Shelby left me finally to go to Cerro de Pasco. He did, I am told, invaluable work for that company; and, I believe, by his unfortunate death in an automobile accident, the metallurgical profession was deprived of one of its most valuable members.

During the years that you were at Globe was your attention ever called to the low-grade deposits on which the success of the Miami and Inspiration companies is founded?

No; I knew of the claims, but I had no comprehension of their latent possibilities at that time.

Did you make any changes at the smelter?

After the concentrator was completed, it became evident to me that the blast-furnaces at the Old Dominion ought to be supplemented by a reverberatory plant, because the fine concentrate tended to blow out of the blast-furnace about as fast as it was put in, and the mechanical loss of copper was excessive. At first Dr. Douglas was unwilling to authorize me to proceed with this heavy expenditure; however, he gave his consent finally, but about that time I left the employ of Phelps, Dodge & Company, and the furnace was never built. It is interesting to speculate on what the result might have been had a reverberatory plant been erected by the Old Dominion company, for the reason that in that event undoubtedly it would have contracted to smelt the Miami concentrates and thus would have gained knowledge of latent possibilities that would have been invaluable. Such a de-

velopment in metallurgical practice would have revealed the potentialities of the Miami district outside the Miami Copper Co.'s property.

You are referring now to a period before the Inspiration Consolidated Copper Co. was organized; do you refer to the group of small mines such as the Black Warrior, Keystone, and Live Oak?

I am referring to the groups of claims that have since become the property of the Inspiration Consolidated Copper Company.

You had a lot of water in the Old Dominion?

We had a lot of water. Previous to my coming they had purchased a number of large Prescott direct-acting steam-pumps. These pumps were flagrantly extravagant in the use of steam, and proved a source of great expense. In spite of the fact that the company had just purchased these pumps, I made up my mind that, with the great quantities of water to be handled, a higher-class pump should be used; accordingly I arranged to put in high-pressure boilers, and purchased four triple-expansion duplex crank-and-flywheel pumping-engines, each of 1000 gallons capacity, from the Nordberg Manufacturing Co. These pumps were delivered, but not installed, during my regime as manager of the Old Dominion. I understand that when they were installed some years later they reduced the pumping expense about \$10,000 per month.

How much water were you pumping?

The amount of water varied, but at that time it averaged about 3½ million gallons per day from a depth of about 800 feet.

What fuel did you use?

Oil. That reminds me; it was during this period that Dr. Douglas purchased the El Paso & Northeastern Railway in behalf of the Phelps Dodge interests. At the same time the same interests purchased the Dawson Fuel Co. The coal-washer at Dawson, New Mexico, was inefficient, and it was evident that the slack or crushed run-of-mine coal had to be washed in order to produce a superior grade of coal for coking. At this time I went to Europe to study the progress that was being made in England and Germany in washing coking coal, and on my return in 1905 I designed a coal-washing plant in conjunction with Thomas H. O'Brien, who afterward became manager for the Dawson Fuel Co. and is now general manager for the Inspiration Consolidated Copper Co. This washing plant was a new departure in the coal-mining industry, and I think that most of the good people of Colorado and New Mexico thought that I was mildly insane in building it, because I introduced steel construction and reinforced concrete work, building a substantial plant, instead of the usual ramshackle wooden affair that requires excessive repairs and a maximum labor cost. Although the plant became antiquated in time, it was very successful; it did clean work at a minimum cost, and produced good coke.

Do you remember any figures of cost?

No; it is too far back. All I remember is the costs were

as estimated, the coal was cleaner, and the saving of coal was greatly increased. For the construction of this plant I recommended Horton Jones to Mr. O'Brien as construction engineer. He was a genius at this kind of work. Later he did splendid work for me in the construction of the Arizona Copper Co.'s smelter, and is now assistant manager, I believe, for the International Nickel Co. at Sudbury.

It is interesting to note how men like Messrs. O'Brien and Jones have been able to apply their knowledge of engineering and of human nature with equal success in the production of one mineral as of another, although

sonal benefit. The point of Dr. Douglas's character that stands out in my mind was his imagination. He had great insight, and in conjunction with William E. Dodge and D. Willis James, who had the shrewdest financial sense, he built up a great and wonderful enterprise. I want to lay emphasis on his remarkable sagacity in foreseeing the latent possibilities and resources of the South West, and upon his untiring efforts to improve metallurgical processes.

When did you begin your connection with Cuanea?

While I was at Globe I acted as consulting engineer for the Greene Consolidated Copper Co. in so far as their con-

THE ARIZONA COPPER COMPANY'S SMELTER AT CLIFTON, ARIZONA

usually a colliery experience is not supposed to be applicable to metal mining.

I think that is a mistaken idea. The different classes of mining and metallurgy, after all, are parts of one great art. Most of the advances made in any branch of mining or metallurgical industry are linked to the treatment of products in other branches. For instance, the only difference between washing coal and concentrating ore by gravity was that, in the one case, you saved the heavy material and threw away the light; in the other, the reverse; but the principles of gravity concentration applied to both, and there is every reason to believe that the engineer with extended experience in ore-dressing can bring good ideas into coal-dressing. The same reasoning applies generally to handling and transporting materials.

Obviously, your association with Douglas was one of the most important features of your career.

Yes, indeed. It gave me a wide variety of experience. My close association with him was undoubtedly of per-

centrating operations were concerned. I had supervision of the remodeling of their first concentrator and the building of a new one, and in that connection I employed David Cole, who at the time was the superintendent of a small mill at Aspen, Colorado. I found Mr. Cole a very competent young man, and, as is usually the case when a man comes from one branch of industry to another, he introduced new ideas effectively.

Did you then assume the management of the Greene Consolidated?

No; I did not. I was offered the management of the Greene Consolidated, but at that time was not satisfied that it could be properly financed, and thought it better not to accept. During this time and previous to this time I had become acquainted with William C. Greene. I admired the many good points in his character. He was always loyal and generous to his friends, and responsive to any sentimental tie or call from them. I owe to him my first opportunity to make any considerable sum of

money, as he let me have 5000 shares of stock in the America Mining Co., at Cananea. Subsequently I disposed of sufficient of this stock to pay its cost to me and invested the balance in the Greene-Cananea Copper Co. At the end of 1906 the Greene-Cananea Copper Co. was formed and control of its direction was assumed by the present board of directors. I was offered, and accepted, the position of general manager and took active charge in March 1907.

You speak of the present control. Does that mean the Anaconda company?

No, but Anaconda and Greene-Cananea have many common shareholders and the same executive direction.

So you then formed a new and very important professional connection?

Yes, I formed a very important professional connection at that time and also became associated with some splendid men. My direct superior in New York was W. D. Thornton, who since that date has been my constant friend and advisor, and we have worked together in a most harmonious way. Also when I went to Cananea I found a splendid set of men on the general staff. My old friend, James H. Kirk, was superintendent at the mines, and Charles S. Shelby had charge of the smelter, David Cole had the concentrator, Tindall Evans the traffic and purchasing department, and George Young was the secretary of the company. All these able men needed was encouragement and help, and after a general plan of work had been laid out for them, to be shown how to work together. I made no changes in the general staff, except that I reduced it somewhat, and all, except Shelby, continued with me during the major portion of the time I was in active management of the property.

Were there any special technical problems that you had to solve during this period?

Yes. The mines were under-developed and required a great deal of planning and a great deal of money spent in order to centralize, provide new outlets, and open up further ore-reserves. The smelter was an impossible structure and, aside from the bedding plant, had to be completely re-constructed. Steps had to be taken to induce the railways to give Cananea at least approximately the rates that neighboring points in Arizona were enjoying. It was just after I took charge of this property that the panic of 1907 came, and in order to be successful it was apparent that the operating costs at Cananea had to be reduced about 9 cents per pound of copper. This was done but it took all of the planning and hard work of the entire organization to accomplish it.

What was your next professional connection?

While I was at Cananea I was consulted on various matters by the Anaconda interests. I also undertook to act for three years as consulting engineer to the Arizona Copper Co. During that time I built its new reduction works at Clifton. I also became consulting engineer for the Calumet & Arizona Mining Co. at Bisbee. It happened that the old Calumet & Arizona Mining Co. and

the Superior & Pittsburg Copper Co., which were affiliated in ownership, wished to consolidate, or, rather, the latter company wished to go out of business and sell its physical properties to the Calumet & Arizona Mining Co. for stock in that company. James S. Douglas and I were employed to recommend a proper basis for consolidation. Following this work, I was employed as consulting engineer by this company, and in association with John C. Greenway, its general manager, built the new smelting works at Douglas in 1911 and 1912. In connection with the construction of these smelters, we necessarily had to have assistants, so we employed C. H. Repath and A. G. McGregor, who designed the Calumet & Arizona smelter under our direction. Later Mr. Repath retired from the firm, but Mr. McGregor became associated with me in the design of the Arizona Copper Co.'s smelter and the smelting works of the International Smelting Co. at Miami. He has developed into a mechanical engineer of the first rank. Since that time Mr. McGregor has gone into practice on his own account, and has recently designed the United Verde Extension smelter and the new smelter of the Cerro de Pasco Mining Co. in Peru, with which operations I have had no connection.

In designing these smelters did you introduce any new features?

No, I cannot say that I originated any really new features in the new smelters in Arizona except that progress was made and careful observation was given to work that was being done elsewhere, and an attempt was made to employ, as far as possible, the best standard practice. As a matter of fact it is rather dangerous to introduce new features in new plants; new features should usually be introduced in established works. I did select new ideas and decide on processes. Gmahlring and Shelby had developed the idea of fettling through ports in the roof of a reverberatory, and this idea was carried forward. In the meantime David H. Browne, at Sudbury, had developed the idea of side-feeding the charge and doing away with fettling by protecting the walls of the furnace with the charge itself. These ideas were adopted and developed, and since hand-fettling was no longer necessary and it was therefore practicable to widen the furnaces, I decided it was safe to use larger units, and so I made the first departure in the Arizona Copper Co.'s plant by increasing the width of the reverberatory furnace beyond the old maximum of 19 ft. The latest furnace that I have erected at the International plant is 25 feet wide.

While at Cananea did you smelt any custom ore?

Yes; I had become convinced that, with the exceptionally rich concentrate Miami was able to produce, a high saving could be made, and that the treatment of the concentrate would lead to the building of a smelter at Miami, basing my faith on the belief that great mechanical losses could be avoided by proper construction and by the adoption of Dr. Cottrell's invention, which was then attracting attention.

How did you treat the Miami concentrate at Cananea?

I had to use a temporary expedient. Part of it was

treated in the reverberatory furnace, but a large proportion was dried and blown with the blast through the tuyeres of the converter. In this connection, I built good hoods and an ample dust-chamber for the converters, in order to avoid mechanical loss. Of course, concentrates could only be blown in while the converter was turned up. Later, a contract was made with the old Inspiration company for the treatment of its concentrate, which positively assured the building of a new smelter at Miami. This was done in 1910 or 1911. In this year my principals purchased the Live Oak property and later on it was consolidated with the Inspiration as the Inspiration Consolidated Copper Company.

By your "principals" you mean, I presume, what is usually called the Anaconda interests? Also I would

a high return in case they are successful; for the reason that, if expansion is desired, then encouragement has to be given to the expenditure of money, based on the opinion of competent engineers, whose opinion cannot be confirmed until after the money is spent.

What were your metallurgical plans?

Our original intention was to build a wet-concentration plant. Mr. Mills employed H. Kenyon Burch as engineer for the designing of a new concentrator; a mill of 10,000 tons capacity was designed, and the steel structure actually erected. During the erection of this building the Minerals Separation people brought to our attention certain tests that they had made on Inspiration ore.

These tests were made by E. H. Nutter at San Francisco?

THE NEW CORNELIA COMPANY'S PLANT AT AJO, ARIZONA

ask whether W. B. Thompson was not in control of the old Inspiration company?

Yes; W. B. Thompson was in control of the old Inspiration company and remained nominally as president of the Inspiration Consolidated for a time. The management was put under my direction by Thornton. The important question then arose of selecting a general manager; I chose Charles E. Mills for this position, because I considered him the best man in America to undertake the development of a low-grade copper mine and the construction of great works in conjunction therewith. The development of the Inspiration Consolidated was an exceedingly interesting problem and required great faith on the part of the directors and the shareholders. The engineers had faith and believed that they could make the property a very valuable one, but the board of directors had to provide about \$13,000,000 of gold coin to justify this opinion and wait until after this vast sum was spent before they obtained the concrete results. In this connection, I think that attention should be brought to the necessity of new enterprises involving risk being assured

I believe they were. It was decided, therefore, in spite of heavy interest charges, to delay construction, and arrangements were made for the Minerals Separation company to furnish us with a 50-ton testing-plant, and we conducted experiments with this plant for some months.

Jointly with them?

With their assistance and advice, Yes. The saving was so high and results generally were so encouraging that Mr. Mills then erected a 500-ton testing-plant and tried the froth-agitation process on a scale that he estimated at the time as being equal to the capacity of a single unit in his new mill. At the same time he conducted tests on grinding-machinery and pneumatic-flotation machines. Dr. Rudolf Gahl was employed by him in these investigations, and developed a flotation-cell that is now in use in all but two sections of the new mill. The tests were so thoroughly successful that froth-flotation was adopted. Another important feature was the adoption of a steel-ball mill for fine grinding. I believe this was really one of the large departures in milling. The consequence of

the adoption of flotation and the use of the Marcy ball-mill, which requires very little floor-space, was that our mill, in a building originally designed for a 10,000-ton plant, was able to treat 18,000 tons per day.

Do you believe that the Minerals Separation people are entitled to the royalties they demand?

I don't care to enter into a controversy with which I am in no way connected. I will say that I believe that the Minerals Separation people brought their process to our attention and that, whether their patents are valid or not, they rendered to us at least a great professional service, and I believe that the arrangements that we have with them are equitable and reasonable under the conditions and they certainly bring to both sides peace of mind.

Of course, you have a contract far more favorable than is granted to most mining companies?

As to that, I have nothing to say. In conjunction with the development of the mine and concentrator at the Inspiration, the International Smelting Co. had to build a smelter in which to treat the Miami and Inspiration concentrates. This plant as already stated was designed by McGregor under my direction. L. R. Wallace was superintendent of construction and operated it for several years most successfully. Wallace was the superintendent of the smelting works of the Detroit Copper Co. for many years before he undertook this work. He is an able manager and a metallurgist of the first rank. I sent him from this plant to Chile as general manager for the Andes Copper Co.; and this position he holds still. On account of the fineness of the flotation product it was imperative to avoid mechanical losses as far as possible. For this reason I purchased from the Western Precipitation Co. the right to use the Cottrell process at this plant, in so far as the saving of solid particles was concerned. Exceedingly strong and massive calcining-furnaces were built on account of the tenacity of the wet concentrate, and special methods were adopted for the avoidance of dust in handling calcine from the hoppers and to the furnaces. These have since been improved by L. O. Howard, the superintendent, so that remarkably little loss is sustained in the operation of charging the furnaces, and the calcine-house and the reverberatory feed-floor are as clean as any portion of the smelter.

The treatment of flotation concentrates has given a good deal of trouble to smelter-men, who probably did not at first realize the true character of the product. I would like to ask you whether you would advise the use of some drying-machine between the filter and the reverberatory furnace?

No; as a rule there is some table-concentrate produced in a flotation mill; this helps by admixture to make the flotation concentrate more porous, and reduces the average moisture. I believe that, if sufficient care is taken, the concentrate should not be sloppy, and, of course, it is always advisable in a metallurgical process 'to take one bite at the cherry' if one can.

In other words, avoid a multiplicity of operations?

Yes. The Cottrell process was applied, of course, to the calcining-furnaces and was also applied to all converter smoke; but it was not applied to the reverberatory furnace smoke, in spite of the fact that we feed these furnaces practically continuously and with a dry pre-heated charge. It is true, there is some dust-loss from our furnaces, but the best test that we could make indicates that it would scarcely pay to go to the great expense of treating the large volume of reverberatory gas in the Cottrell plant. So far as we can determine, the mechanical loss—that is, all the loss apart from the slag—at this plant amounts to about 0.8% of the total copper content. When we first started the plant, we found with this class of material—flotation concentrate—there was a tendency to liquation in the reverberatory furnace, that is, the iron oxide would tend to combine with a part only of the silica, and liquate out with the matte, leaving a silicious putty-like mass floating on the charge, which caused the copper content of the slag to be abnormally high. Mr. Howard has adopted the method of tapping his reverberatory slags on a line above the matte but below this crust, and finds that after a certain amount of the crust has accumulated it fluxes off at the bottom about as fast as it accumulates on top. Careful tests extending over 18 months have shown that by this method he has saved about 50 tons of copper per month.

Won't you say something about the New Cornelia enterprise?

In 1911, John C. Greenway took an option on the controlling interest of the stock of the New Cornelia Copper Co. on behalf of the Calumet & Arizona Mining Co., and started drilling operations at Ajo, Arizona. The results of his drilling operations indicated about 11 million tons of oxidized copper-bearing monzonite, averaging about 1½% copper, and some 40 million tons of sulphide material of about the same grade. Later on, through cash and stock purchases, the Ajo Consolidated Copper Co.'s physical property was acquired, bringing the tonnage of oxidized ore to about 14 million tons, and, with additional drilling, increasing the sulphide tonnage to something over 50 million tons, with further possibilities.

From whom was the Ajo Consolidated property purchased?

From James Phillips, Jr. The ore is a granitic rock, usually called monzonite-porphry, containing copper minerals associated with little, if any, pyrite, but with some magnetite. As is usual in deposits deficient in pyrite, the copper did not migrate, but was oxidized *in situ*. There is scarcely any zone of secondary enrichment between the oxides and sulphide, and this secondary zone is very thin. It was evident that if the oxidized material could not be treated commercially it would be simply an overburden, which would have to be mined and thrown away, whereas if it could be treated commercially it at once became an asset instead of a liability; an open-pit mine with practically no overburden could be started, and ore would be at hand with the first rock that the steam-shovel lifted.

The decision to treat the orebody by a leaching process required some courage.

Like the new mines that have come forward through the improvement in metallurgical process, the outcome was based upon the opinion of the engineers associated with the project. This point was thoroughly realized by Colonel Greenway and myself, and we spent several years studying the subject in conjunction with competent engineers. In this connection, we consulted Stuart Croasdale, F. L. Antisell, and the firm of Pope & Hahn. Our own engineers included James A. Potter and Henry A. Tobelmann. The tests originally were made at Douglas on small amounts of ore brought from Ajo. Later, a one-ton plant was erected at Ajo, followed by a 40-ton unit. The results were so encouraging that we jumped from the 40-ton unit to the 5000-ton plant that is now in successful operation. Once the process was decided upon, the work of construction proceeded, and Mr. McGregor was employed to design the plant under the direction of Colonel Greenway and myself. The process is simple. We found that a high extraction could be made on the oxidized ore with a dilute solution of sulphuric acid. We found that, although considerable amounts of alumina and iron oxides were dissolved, the former salt gave little trouble in electrolytic precipitation, and the latter could be controlled through the use of sulphurous acid. In consequence, we decided to recover the copper in major part electrolytically, reducing the ferric sulphate to ferrous sulphate by subjecting the solution from the leaching-vats to the action of sulphurous gas before it went to the tank-house for treatment.

In what way is the SO_2 reduction applied?

The entire process has been described technically by Tobelmann and Potter. The chief feature is the establishment of an enormous surface of contact between the liquid and the gas. Necessarily, as the iron and alumina accumulate, a portion of the solution has to be discarded. A part of the copper from this discard is then recovered electrolytically, and the remainder by precipitation on scrap-iron. Most of the cement-copper thus produced is re-dissolved with a corresponding reduction of a portion of the ferric iron.

In other words, you use the cement-copper in part to reduce the ferric sulphate?

Yes. The plant has worked successfully, and has treated several million tons of ore, producing copper at a low cost.

Did you draw upon the experience of others?

No, I cannot say that we did. We used whatever information we could get, but there is absolutely nothing in common between our work and that at Rio Tinto, for example; and the splendid work of Cappelen Smith at Chuquicamata did not apply to our ores or conditions.

I understand that your associates have become owners of an oilfield in California?

Two companies with which I am connected have purchased the old Peerless oil property in the Kern River

field in California and are operating it under the name of the Arizona Oil Co. This purchase was not made, because the companies wished to enter into a new industry. They considered the property well worth the purchase price, but, still more important, its possession protected their fuel supply. At present the oil for the copper industry of Arizona is coming almost exclusively from Tampico, and the oil that the Arizona Oil Co. produces is sold on the market, but with an agreement, any time we wish, that Inspiration and International will be furnished with California fuel-oil up to total requirements.

This means that, in case of a revolution in Mexico, you would have not only the supply from your own property, but the oil company would also provide you with whatever more was necessary?

Yes, within reasonable limits. Two things are now coming up, of exceeding importance. One of them is the assurance of a fuel-supply, because, not only is the cost of coal nowadays tremendous, but the Trinidad and Raton coals are not well adapted to reverberatory work. I feel that the cutting off of our oil-supply in the South-West might force the development of methods other than the fire process for the reduction of copper. We can probably obtain our power from other sources than coal or oil—that is, from streams—but I am inclined to believe it is possible that, rather than operate with high-priced impure coking-coals as smelting-fuel, we would develop wet methods for the treatment of sulphide and mixed ores, with the direct production of refined copper. The other important point is the necessity of decreasing the present freight-rates. I have recently had a study made of what the increase in freight means to four of the large mines with which I am connected, and it shows that if operating somewhat under normal capacity these mines would be now paying out in direct freight \$3,500,000 a year more than they would have paid if 1916 rates prevailed. This amounts to an increase in direct freight charges alone of about 1½¢ per pound of copper. In consultation with other mine operators in the South-West I find they check out about the same increased cost due to increased freight charges. Under normal conditions the South-West, including New Mexico, Arizona, and northern Sonora, can produce about 800,000,000 lb. of copper, which means an increase in direct freight paid of about \$12,000,000 a year (77%) for the entire district. This has nothing to do with increased costs of labor or supplies. Recently there has been a tendency toward some reduction in freight, and it would appear that shortly a rate of \$16.50 on copper will go into effect, being a reduction from a maximum of \$22 per ton, but still some 65% higher than the pre-war rate. The railroads are in a very difficult position; their business has been disorganized, and operating expenses are far higher than they were formerly; unless freight rates can be reduced, either the public will have to pay a sufficient price for copper to absorb the increased freight, which it does not show any inclination now to do, or the mines must continue idle, as they now are, or a new outlet to tidewater must be provided.

Ancient South American Milling and Amalgamating Practice

*The *trapiche*, or mill, for grinding gold and silver ores, is a simple and rude piece of mechanism; its moving power is constructed after the same fashion as the mills used throughout Chile, and in some parts of Spain and France, for grinding corn. A place is chosen where a small current of water, whose section will present a sur-

LEFT: 'TRAPICHE' USED IN CHILE FOR GRINDING ORES
RIGHT: FLOUR-MILL

face of six inches in diameter, can be brought to a spot where it can fall perpendicularly ten or twelve feet. At this place a well is built of this depth and about six feet in diameter; in its centre is fixed an upright shaft upon a central brass pin; it is confined above by a wooden collar. A little above its foot, the shaft has affixed to it a small wheel, around which are fixed a number of radiating spokes that are shaped at the ends somewhat like hollowed cups; these form a horizontal wheel about four feet in diameter. Upon the periphery of the cups, the jet of water is made to impinge with all the force it has acquired in falling down an inclined and nearly perpendicular trough, formed by scooping out the solid trunk of a tree. The application of this force causes the wheel to revolve with a quick rotatory motion. The arm extends about six feet above the top of the well; at about half this height is fixed a small horizontal arm, four feet long, which serves as an axle to a ponderous stone of granite, whose diameter is from four to six feet, and which is made to roll upon its edge in a circular trough that is sometimes made of granite, sometimes of hard wood.

The weight of this stone, assisted by its velocity, effects the pulverization of the ore; in some cases it is taken out in a dry state and subjected to the application of sifting.

in order to separate the finer powder for amalgamation, and the coarser parts are thrown again into the mill; but more generally, in order to save labor, this separation is accomplished by the action of water. For this purpose a small stream is made to trickle into the annular trough, by which means the pounded ore is mixed into a state of mud, the finer particles being sufficiently attenuated to run off with the superfluous water through a notch made for the purpose in the margin of the circular trough; this is received in little pools, where the pounded ore is left to settle; the clear water runs away, leaving the powder at the bottom, to be taken to the place of amalgamation.

The *ingenio*, or stamping-mill, is moved by water by means of a small undershot wheel, five feet in diameter and one foot broad, the float- or paddle-boards of which are about one foot square, and move in an inclined trough, down which water is allowed to run. The impetus of the water falling upon the float-boards causes a quick revolution of the wheel, which is fixed upon one end of a long horizontal shaft, furnished with five or six cams at different places around the shaft, so that one is made to act as soon as the other has ceased its operation. Behind this shaft are arranged as many rods as there are cams, each furnished with a projecting tooth, against which, at every revolution of the shaft, the cam comes in contact, and thus lifts the rod a small height, which again falls down by the action of the cam. Each rod is furnished at its bottom with a copper hammer, or pestle, weighing 200 lb., which works in a mortar of stone or hard wood. At every revolution of the shaft, each of these hammers

'INGENIO' OR STAMP-MILL

will make a blow in succession, and by this contrivance the ore that is put into the mortars is pounded. In those places where the ore is ground dry it is required to be sifted; this is generally effected in a large box, in which a circular cylinder is worked by a common winch-handle, its periphery being covered with pieces of coarsely woven

*Abstracted from 'Travels in Chile and La Plata', by John Miers; published in 1826.

hair-cloth; the finer particles pass through the sieves into the box, while the coarse fall out at the opposite end of the cylinder, which is inclined for this purpose.

The amalgamating floor, called the *cancha* or *patio de beneficiar*, is a level place in the open air, about twenty feet square. The finer pulverized ore is brought and deposited in heaps, containing each half a *cajon*,† which are separately kneaded into a mass called a *cuerpo*. They mix with each about two *quintales*‡ of salt and a quantity of dry mule- or horse-dung, which is incorporated well together, and turned over with a spade several times for two or three days, until it begins to ferment; they then add to it a certain quantity of quicksilver. The quicksilver is put into a soft goat's skin, bag, or purse, which they squeeze with the hand, so as to make it run in a shower of minute globules, the quantity of mercury used being apportioned to the nature and richness of the ore; those of silver require generally from 10 to 20 pounds to each *cuerpo*. Gold ores consume much less; the quantity is judged by experience. The mass is moistened with water, and kneaded by the pressure of the foot of the workman six or eight times every day. There are generally from 10 to 30 *cuerpos* upon the floor at one time, and the workman goes from one to the other in succession, until all are kneaded. He then begins again at the first, and so continues the operation, taking care after each kneading to beat up the mass smoothly in the form of a cone. In Chile, the heat of the sun is generally sufficient to ensure satisfactory amalgamation; but in some of the high table-lands of Peru, where the air is

'CANCHA DE BENEFICIAR.' PREPARING THE 'CUERPOS'

cold, the amalgamating floor is built upon arches, under which a fire is maintained to preserve the necessary temperature. During the winter in Chile, the amalgamation often requires three weeks, whereas in summer eight or ten days is sufficient. When the process is supposed to be completed, the foreman takes a small sample of each *cuerpo*, washes it in a small earthen bowl, or in a bullock's horn, to separate the amalgam, and judges by its color and consistence whether it has reached the precise point. If the amalgam, or, as he calls it, *la pella*, be hard, more quicksilver is added to the *cuerpo*, and the mass is again kneaded. If on pressing the sample under the thumb it forms a cake, and adheres to the skin, the amalgamation is judged to have been carried to the correct point. If, in forming the cake, a portion of quicksilver escapes from it,

the mercury is not sufficiently incorporated, and the mass is left to ferment some time longer. If the color of the amalgam be dark, more salt and dung are added, and the mass is again kneaded and fermented.

The *cuerpos* are then carried to the washing places. The first of these is a small shallow square reservoir made

MILL USED TO GRIND THE CONCENTRATE

of brick and plastered with lime. Across this is stretched a sort of hollowed apron, made of a piece of hide, suspended at the corners from the angles of the pit. The reservoir is filled with water into which a fresh current is always running; the displaced water is made to flow along a narrow gutter into a second reservoir. Upon the hide apron the *cuerpo* is placed, and is carefully kneaded by the hand; the saline, vegetal, and earthy matters are carried off by the waters, and the heavier metallic particles fall into the concavity of the hide. Further off at short intervals in the course of the inclined gutter, are made four or five small reservoirs of the size and shape of inverted sugar-loaves. Across these, in like manner, are stretched small leather diaphragms, so that any very small metallic particles that may have escaped from the first reservoir, suspended in the running stream, may be deposited in these successive receptacles. The amalgam, by these means, is separated and collected at a trifling expense. When a sufficient quantity is collected, the *pella* is put into a woolen bag, shaped like a cone, with the point downward; it is then hung up, to allow the superfluous mercury to drain off. The mouth is then tied up, it is laid between two boards with a weight on the top, and the excess quicksilver is expressed. Thus the amalgam is shaped into cones, for distillation.

Another mode of extracting the gold, where it is minutely disseminated in grains in a soft rock, is by washing—a process much more economical, and adopted by the poor people. This can only be done where a small spring of water issues from the side of a hill. The place where the operation is effected is called a *lavadero*. The little springs often bring down into the ravine a large quantity of clayey matter that contains minute particles of gold, mixed with iron sand. It is usual to change the course of the stream to where gold is supposed to be most abundantly existing; and, to command a greater force of water from these little springs, it is advisable to form a pit on the side of the hill, and to bank it so as to accumulate a supply of water. The workman then scrapes the earth from the side of the hill and opens the embankment. The water flows over the collected earth and forms a small channel, by which the water, thus rendered muddy,

†A 'cajon' is a box, probably used as a measure.

‡A 'quintal' is about 100 pounds.

is conveyed to his hut. While descending the declivities mountainside, no more apparatus is needed than a small gutter to confine the water; but, where it crosses a less inclined valley, the muddy fluid is made to flow down troughs that are hollowed from the trunks of trees. The operator continues to turn over and stir up the earth while the water flows over it, so that it may carry off all the earthy matter in which the particles of gold are suspended. After it is sufficiently washed, he examines carefully the stony and gravelly residue, for whatever *pepitas*, or large grains of gold, may be found, though rarely, disseminated in the rock.

The muddy water thus conveyed to the hut of the gold-washer is received upon a large stone, whose surface is in the form of a shallow basin. A notch in the exterior allows the water, which has in great measure deposited its heavier particles, to flow off, by means of another trough, to another similar stone basin, and in the same manner into three or four others in succession. The auriferous particles are thus allowed to deposit themselves in these receptacles, while the earthy lighter atoms, still suspended, are carried off by the running water. The gold thus collected is mixed with a quantity of ferruginous black sand and stony matter; the mixture must be triturated, a process that is effected in a rude and simple kind of *trapiche*, formed of two stones, the under stone being about three feet in diameter, and slightly concave. The upper stone is a large spherical boulder of syenitic granite, about two feet in diameter, having on its upper part two iron plugs fixed oppositely; to these is secured, by lashings of hide, a transverse horizontal pole of *canelo* wood, about ten feet long. Two men, seated on the extremities of this lever, work it up and down alternately, so as to give to the stone a rolling motion, which is sufficient to crush and grind the materials placed beneath it. The washings thus ground are subjected to the action of running water upon inclined planes that are formed of skins; by which process the silicious particles are carried off, while the heavier grains of gold, mixed with a portion of ferruginous matter, are extracted by a loadstone; it is again washed until nothing but pure gold-dust is left behind. The process is managed with much dexterity; and, if there were much gold to be amassed it would afford very profitable employment; but generally the small quantity collected is sufficient only to afford subsistence to the few miserable families employed at these works. It is probably the accidental finding of a rich prize on rare occasions that excites the constant hope of good fortune, and keeps the washers at this employment.

The distillation of the amalgam is effected in a sort of reverberatory furnace. It is constructed of sun-dried bricks and mud. Including the fireplace at one end, its length is fifteen feet, its breadth about four feet. The fireplace and hearth are raised four feet above the ground; the chimney is of small diameter. In the centre of the hearth is a circular hole, in which is cemented a conical earthen jar, two feet six inches long, and fourteen inches in diameter at the top, diminishing to half an

inch in diameter at the bottom. This jar is so placed that the mouth is raised a few inches above the hearth. The nozzle bottom is received into a large earthen jar, filled with cold water, and placed in an arched chamber beneath the hearth. A circular grating made of hoop-iron stands upon three legs, the claws of which rest upon the inner edge of the mouth of the jar. Upon this grating, a tile is placed, and on it a ball of amalgam. A conical rounded head, of just sufficient capacity to contain the tripod and the amalgam, is made to fit closely upon the mouth of the jar. The joint is secured by a plastic lute,

AMALGAM-FURNACES

so that none of the vaporized mercury can escape. When the alembic is thus prepared, the opening at the side of the furnace is closed, and the fuel in the fireplace is lighted. The fire is briskly kept up during the operation, and, reverberating around the alembic, keeps it at a red heat, by which the quicksilver is converted into vapor, and is condensed in the earthen vessel placed beneath the jar, when it again becomes running mercury. The silver in a pure state remains in a porous mass upon the tile; it is called *plata en piña*.

THE value of the output of refined lead in the United States from domestic ores in 1918 was \$76,667,000, as compared with \$94,333,000 in 1917, a decline of \$17,666,000, or nearly 19%, states a U. S. Geological Survey bulletin.

Agitation in Flotation

By Frederick C. Moses

Agitation, when considered in connection with modern froth flotation, has three functions:

1. The mixing of the oils or reagents in the pulp; or, as it is incorrectly called, the emulsification of the oils or other reagents.

2. The production of the air necessary for froth flotation. This step is more commonly called aeration.

3. As a means of increasing the circulation of the pulp in the flotation apparatus, the fundamental object being to cause the sulphides to be entrapped in the overflowing froth.

Each of these three functions is important, but the relative importance of each varies under special conditions; each is separate and distinct. All the three results mentioned may occur at the same time, and all may be accomplished by the same means; but this is usually for the sake of convenience, and not because the mixing of the oils and the aeration must be carried out simultaneously. In fact, there are many cases where these two phases of operation occur at different times and independently of each other.

MIXING. The general use of the term "emulsification" in connection with the mixing of oils or reagents in a flotation operation is incorrect, because of a careless interpretation of the word. Most authorities, when speaking of oil-water emulsions, give the impression that one of the principal characteristics of a true emulsion is its stability. Dr. Bancroft, in his recent book, says that, "The necessary conditions for forming a stable emulsion are that the drops shall be so small that they will stay suspended and that there shall be a sufficiently viscous film around each drop to keep the drops from coalescing".* He also calls attention to the fact that, "When a badly made emulsion is allowed to stand, it decomposes progressively".

Thus, if the oils were properly emulsified, the mixture should remain in an exceedingly fine state of division indefinitely, or for a long period. But the oils, to be effective, must coat the sulphides and the bubbles. If the oil is available for coating bubbles and sulphides, it cannot be thoroughly incorporated with the pulp; it should exist in a comparatively unstable condition, in order that it may be easily available. Bancroft says that, "anything which destroys the film destroys the emulsion. That is why acid destroys a soap emulsion".† The principal function of the acid may be to prevent the formation of a stable emulsion of oil and pulp. One of the principal influences in the production of stable emulsions in mechanical agitation machines is the violent agitation to which the pulp is subjected. It is possible that, in some cases,

the pulp is too violently agitated, from the oil-mixing standpoint; and that the sulphuric acid is added to counteract this. The detrimental action of soap solution is well known; it is probable that this is due to the fact that the presence of such solution causes the oils to form permanent oil-water emulsions. If common salt has proved beneficial to flotation, as reported, this may be due to its property of destroying the stabilizing effect of soap films or other emulsifying reagents in oil-water emulsions.‡

On the assumption that emulsification may be carried too far, it is possible to explain why $\frac{1}{4}$ lb. of an oil added at four places in a series of cells will be more effective than $1\frac{1}{2}$ lb. of the same oil added at the head of the cells. It would seem, also, that the agitation given to a pulp in order to distribute oil throughout it is unnecessary, provided that the oils could be mixed satisfactorily with the pulp by some other means, or provided oils were used of such a nature that they would be sufficiently divided without the necessity for agitation.

At many plants the oil is neither mixed nor distributed in the flotation machine; very heavy oils are used, which are difficult to mix with the pulp. In such cases the oils are incorporated in the pulp before it reaches the flotation machines, by adding them to the dry ore or to the ball-mills or pebble-mills that are used to grind the ore previous to flotation. Mixing by agitation may also be avoided by using oils that are light enough to be mixed sufficiently by the travel of the pulp through the mill launders, elevators, or flotation machines, or which distribute themselves throughout the water of the flotation feed. Many flotation operators state that they cannot use crude coal-tar, or other heavy oils, because of the difficulty of emulsification. As an alternative, certain lighter fractions, which do not require the violent mixing, are being used; results are as good or better than those obtained by the use of heavy oils. It is not the intention to give the impression that heavy oils are not required, nor that, in certain flow-sheets, the violent mechanical mixing is not desirable. The latter is necessary when coarse sand is being treated, and when this class of mixing is required to keep the heavy constituents of the pulp in suspension. Other special cases might also be cited.

AERATION. Aeration, as applied to flotation, has always been a much-abused word. Flotation was unsuccessful until the importance of air was appreciated. Formerly, the production or incorporation of air in the pulp was considered an unimportant adjunct to violent agitation and its function of mixing oil and pulp.

Air has three important functions, and one unimpor-

*'Applied Colloid Chemistry', p. 261.

†Ibid, p. 268.

‡Ibid, p. 262.

tant function in the froth-flotation machine. It is necessary in order

1. To increase surface-tension or air-water interface, so that the froth may float.

2. To give air-water interfaces on which the sulphides can attach themselves.

3. To furnish a substance which, when associated with oil, will tend to attract the sulphides.

4. To give an upward direction to the pulp, and so to bring the sulphides in contact with the floating froth.

A bubble consists of a spherical liquid envelope enclosing a gas. Froth is an aggregation of bubbles on the surface of water or pulp. In order to produce the froth that is needed to support the sulphides on the surface of the pulp, a large quantity of air is necessary. The oil, in order to be of use, must spread out in a thin film on the surface of the water or of the bubble. This surface is not available unless sufficient air is present to furnish the gas with which the water can form an interface on which the oil can spread. Bubbles are coated with oil when deep in the machine; the air must be introduced into the body of the pulp. Hence the necessity for aeration, or the incorporation of air in the pulp. A sulphide will not float readily if wetted by water. It is the air that displaces the water and prevents it from wetting the sulphide. Air, or some other gas, must be present in the water to prevent it from wetting the sulphide. This suggests a third reason for the presence of air in flotation pulp.

In all modern flotation machines the sulphides are associated with the froth on top of the pulp. To effect this, it is necessary to carry them upward, or to throw the pulp into this floating froth. Air bubbles in water will rise. Therefore, the air that may be released at the bottom of a pulp column rises to the surface, carrying the sulphides with them. Another method of obtaining the result is to give the pulp an upward direction of flow.

INTRODUCING AIR IN FLOTATION PULP. Methods of introducing or utilizing air are as follows: (1) By mechanical agitation; (2) by positive pressure on the pulp, or by blowing compressed air into it; (3) by negative pressure, or by subjecting the pulp to a vacuum; and (4) by the production of some insoluble gas in the pulp.

The aeration of flotation pulp by mechanical agitation is secured by direct or indirect suction, whereby the air is sucked into the agitating chamber of the machine, and is there entrapped in the pulp. This aerated pulp then flows to a spitzkasten or settling box, where the entrapped air is slowly released, and rises in the form of bubbles to the surface of the pulp. All mechanical-aeration machines depend on this principle, regardless of the kind or shape of the agitator or the form of the box in which it revolves. Some types of machines draw the air into a vortex formed by the rapid revolutions of the propeller; others suck the air down a hollow shaft; a few depend on sucking the air through openings in the machines or through open shaft-ends. Some types are peculiarly adapted to certain conditions; some are efficient as mixers and some are efficient as aerators, but the principle in each case is the same.

PNEUMATIC MACHINES. The so-called pneumatic machines constitute the second most popular type of flotation apparatus. In these the agitators are usually omitted. The heavier oils are mixed before the pulp reaches the cells, and the air is blown directly into the pulp through porous-canvas, porous-brick bottoms, or by means of pipes that are submerged in the pulp. The air is produced by a low-pressure blower. This, is, undoubtedly, an efficient method of aerating the pulp; but the absence of agitators is sometimes a disadvantage.

THE VACUUM PROCESS. One of the first successful frothing processes of flotation was the Elmore vacuum process. Although thus termed, its success depended on aeration. The difference between this process and the pneumatic process is in the source of air. In the latter, atmospheric air is furnished by a blower; in the Elmore process, the air used is that which is dissolved in the water in the pulp. Of course, ordinary water contains air. Under most operating conditions there is sufficient air in the pulp to furnish enough froth for successful flotation. The dissolved air in the Elmore process was made available for froth formation by subjecting the oiled pulp to a reduction in pressure, by placing it under vacuum. The dissolved air came out of the solution in the form of fine bubbles, which rose to the surface and carried the sulphides with them.

CARBON DIOXIDE PROCESS. In this process, limestone and acid were added in the correct quantity to produce bubbles of carbon dioxide gas that, as they rose to the surface, carried the sulphides, and formed the supporting froth on the pulp surface.

DIRECTION OF PULP FLOW. Bubbles rising in the pulp will carry sulphides with them, but only a proportion of what is found entrapped in the froth reaches the surface in this way. The remainder are entrapped by being thrown into the froth, by agitation and circulation. On inspecting the operation in a machine with a glass side, the bubbles may be seen to carry their burden of sulphides upward. The pulp moves in such a manner that a stream is continuously in contact with the floating froth. As the material moves up into this layer, both sulphide and gangue are entrapped and held, with different degrees of tenacity. The sulphides have the greatest affinity for the bubbles; they are gradually carried to the top of the froth column and over the lip of the machine. The gangue is not held so closely, however; it is separated from the froth and finally drops into the pulp. In fact, the degree of this dropping has much to do with the grade of the concentration obtained, and the ratio between the grade of concentration and the extraction. The importance of this method of entangling sulphides in the froth is being realized by flotation operators. It is influencing the design of machines, tending to make them shallower and to cause the feed to enter the machine, not at the bottom but at the top of the pulp. The amount of sulphides that get into the froth in this manner is dependent on the direction of flow given to the pulp by the agitator and the baffles in the machine. It would seem that this function of agitation is most important.

REVIEW OF MINING

CHILE COPPER PRODUCED METAL FOR 11.012 CENTS AT CURTAILED CAPACITY

The Chile Copper Co. has been cutting its operating costs by reason of the depreciation of the peso, although not to the extent that would be possible were the property running at full capacity. During the war period, when the United States was importing nitrates and copper from Chile but sending next to nothing down there except supplies for American-owned properties, exchange went against the dollar to such an extent that labor costs and other items paid for in pesos were higher than ever before. The dollar may now purchase about ten of the Chilean monetary units. The company has reduced output from a monthly yield of 12,000,000 lb. to below 5,000,000 lb. It cost the company 11.012c. per pound to produce its copper in the first quarter of the year, against 11.262c. in the final quarter of 1920. Costs included selling and delivery expenses, but excluded depreciation and Federal taxes, and gave no credit for miscellaneous income. The June 30 statement is expected to show a further cut in costs.

CONSOLIDATED COMPANY OFFERS BETTER TERMS FOR SMELTING ORE

Whether the entry of the Federal Mining & Smelting Co. into the Kootenay lead-zinc district in British Columbia has had anything to do with the sudden change in the plans of the Consolidated M. & S. Co. is not known; however, the Consolidated company, after refusing to give anything but warehouse receipts for the metal content of ores treated since the beginning of the year, suddenly invited the independent mine-owners to a conference at Nelson to discuss fresh clauses for a new schedule of smelting charges. The meeting was a fairly representative one, and included James Anderson, of the Ruth mine; L. R. Biggar, Ottawa mine; Randolph Bruce, Paradise mine; Wilfred Cameron, Rambler Cariboo; Clarence Cunningham, Cunningham group; S. S. Fowler, Blue Bell; R. V. Grimes, McAllister; Paul Lincoln, Noble Five; J. P. McFadden, Rosebery-Surprise; J. B. and Oscar White, Silversmith; and W. E. Zwicky, Cork-Providence, representing the independent mine owners; and J. J. Warren, president; S. G. Blaylock, general manager; and T. D. Bingay, comptroller, of the Consolidated. The tentative proposal put forward by the Consolidated and, after some discussion, approved by the independent owners, probably will form the basis of the new schedule that will go into effect practically at once. The company will pay for 95% of the silver and 90% of the lead content, irrespective of the zinc content, 90 days after sampling of ore. In the previous schedule heavy penalties were made for zinc in excess of 10%. The treatment charge for zinc in such ores is to be reduced from 60c. to 50c. per unit. Prices will be based on London, instead of New York quotations. The company proposes to lower its deduction for exchange from 5% to 3%; this affects only the silver, nearly all of which is sold in the United States. As the independent owners demurred at the 90-day settlement, the company amended it, offering to issue 90-day notes on day of sampling, which may immediately be discounted at the local banks. The independent owners appear to be satisfied with the result of

the conference, and it is expected that considerable activity in the Slocan will result.

HOLLINGER CONSOLIDATED HOPES TO INCREASE CAPACITY BY USING ROD-MILLS

A rod-mill is to be installed in the mill of the Hollinger Consolidated Gold Mines Co., at Porcupine, Ontario. If the mill proves capable of grinding as much ore as the manufacturers claim, additional mills will be added to increase the capacity of the plant. The company is now crushing 3200 tons of ore per day, which figures will be increased by 500 tons immediately. It is reported that a capacity of 5000 tons per day may be obtained if the experiments with rod-milling are successful. Production from the mine has recently returned a gross income of \$900,000 per month, thereby making the Hollinger one of the leading gold mines of the world.

UNITED VERDE EXTENSION BUYS COAL MINE

Consummation of a deal whereby the United Verde Extension Mining Co. acquires 200 acres of coal rights near Gallup, New Mexico, was announced upon the return to Jerome from New Mexico, recently, of George Kingdon, general manager of the U. V. X., E. E. Campbell, mine superintendent, R. L. D'Arcy, engineer, and A. H. Favour, attorney for the company. The coal rights were purchased from the Mutual Coal, Light & Power Co. of Gallup, which has been operating a mine near that town. In connection with the taking over of all of the company's coal rights, the United Verde Extension has acquired right of way for a spur-track connecting the main line of the Santa Fe railroad with the hoist and tippie of the mine, so that coal can be produced on a large scale for shipment to the company's smelter at Clemenceau.

Inasmuch as about 40 acres of the mining property involved in the deal lies within the town of Gallup, the Mutual Coal, Light & Power Co. is retaining surface rights to the land which it is subdividing into town lots and placing on the market. No definite plans for the development of the newly acquired coal rights have been made as yet, on account of the shut-down of the U. V. X. smelter. For the present the Gallup mine will be leased by R. H. Wypur and associates, coal operators of Gallup.

MACHINERY MANUFACTURERS IN DENVER WILL CO-OPERATE IN PRODUCTION

The Denver Engineering Works Co., the Colorado Iron Works Co., the Stearns-Roger Manufacturing Co., and the Queen City Foundry Co., of Denver, have organized a new corporation to be known as the General Iron Works Co. During the coming year the new company will erect a complete modern plant to include machine-shop, foundry, and plate, structural, and pattern departments. A new building 100 ft. wide and 600 ft. long, together with warehouses and storage buildings, will be built near Denver. The object of the plant is to increase the efficiency and scope of production for each of the companies mentioned. Each will retain its identity and will continue to do business along the same general lines as heretofore, except that manufacturing will

be done in the new plant instead of in separate plants as heretofore.

DANIEL GUGGENHEIM, BACK FROM EUROPE, COMMENTS ON THE OUTLOOK FOR COPPER

Daniel Guggenheim, returning from Europe, says that German constructive activity, contemplated electrification of Swiss railways, and water-power development in Italy and elsewhere all gave promise of substantial demand for copper from abroad. He declared, however, that copper producers should devote their main efforts to the development of domestic business, and that, he said, meant getting building started. Mr. Guggenheim indicated that no attempt to increase copper production would be made until greatly increased orders should warrant such action.

Mr. Guggenheim considered high labor costs the principal factor retarding building, and he denounced generally "unsatisfactory and unscientific" methods of handling labor questions.

"Labor leaders should teach their followers that deflation must take place in wages as well as prices, or the industrial situation is disarranged and dissatisfaction to all concerned is the result. It is unscientific to deflate labor by closing factories and throwing men out of work. Labor is entitled to a higher rate of pay than it had in 1914, but for most occupations a lower rate than is now paid is necessary to bring wages in line with prices of materials and products."

THE PROPOSED MINING LAW

The important points of difference between the existing statutes applying to the location and patenting of mining claims, and the proposed new Federal Mining Act, have been arranged in concise form by M. W. von Bernewitz of the U. S. Bureau of Mines. His compilation, which gives the salient features in a convenient table, follows:

Provision	Proposed Law	Existing Law
Discrimination in type of deposit.....	Lodes and placers alike.....	Lodes and placers distinct
Size of claim, acres.....	40	20
Shape of claim	Square	Rectangle
Survey lines	Conform to public lands.....	Any lines
Discovery of mineral needed before location?.....	None required	Discovery required
How long can claim be held without discovery? years.....	5
Terms of extension	Payment of \$50 per acre or \$2000.....
Annual assessment work	\$5 per acre, or \$200.....	\$100
Alternative of assessment	\$5 cash per acre or \$200.....
Failure to comply with law.....	Open to re-location.....	Open to re-location
Period for assessment work or cash payment.....	Calendar year*	Fiscal year (noon July 1)
Extra-lateral rights	None	If vein outcrops on claim
Boundaries of claim at depth.....	Vertical on all sides.....	Vertical at end-lines
Period before patenting, years.....	5	5
Discovery of mineral needed before patenting?.....	Yes	Yes
Right of locators prior to proposed law.....	Valid
Annual work needed before patenting.....	\$20 per acre or \$800.....	\$100 a year or \$500
Alternative of annual work.....	\$20 per acre or \$800.....
Final payment before patenting.....	\$5 cash per acre or \$200.....	\$5 cash per acre or \$100
Area of non-adjacent, non-mineral mill-sites, acres.....	10 or unlimited for large-scale operations	5
Tunnel rights	Limited to claim boundaries.....	Within 3000 ft. from the face
Minerals not covered (Leasing Act of Feb. 1920)....	Coal, oil, oil-shale, phosphates, potash, sodium
State regulations	Repealed	In force with Federal

*As the period under the existing law has recently been changed from the calendar to the fiscal year, no doubt the proposed law, if passed, will be altered also in this regard.

ARIZONA

Hibee.—Copper products fabricated experimentally at the electrolytic plant of the New Cornelia Copper Co. at Ajo are on exhibit at the Lowell store of the Phelps Dodge Corporation. A prize of \$50 is being offered by the Calumet & Arizona Mining Co. for the best suggestion for either increasing the uses of copper or the manufacture of some specific article that will accomplish the same purpose. The display consists of auto and house radiators, copper road-signs, sheet copper, master phonograph records, and other small articles all manufactured electrolytically at Ajo.

It is reported that a body of ore running 20% copper has been cut on the 750-ft. level of the Night Hawk Leasing Co.'s property. It is believed that this ore is the same as that recently opened in a winze on the 650-ft. level on the Lone Star claim.

Clifton.—Following an examination of the property of the Stargo Mines Co., near Morenci, by engineers representing Eastern capitalists, an agreement has been reached by which funds are to be provided for the erection of a mill and for deeper development work. Under the agreement the remaining treasury stock is to be sold. This new work is expected to be started within 60 days. Plans for a cyanide plant are now being prepared by the General Engineering Co. of Salt Lake City, the necessary experimental work having already been completed. The Stargo group of claims lies about a mile and a half south of Morenci, having been finally purchased in June 1920 after a three-year option by the Stargo Mines Co. For two years prior to the closing of the Calumet & Arizona smelter at Douglas regular shipments of ore were made.

Douglas.—The directors of the Hill Top Metals Mining Co. were re-elected at a recent meeting held in Douglas. They are R. O. Fife, A. C. Jones, and R. O. Fife, Jr., who is also general manager. The manager's report stated that

development work would continue at the mine along the same lines as during the past eight years during which time over \$500,000 had been expended. The property is being opened by adits through which the ore will be taken to the mill to be erected.

Jerome.—Sinking at the Verde Central shaft is continuing, although the new machinery ordered has not been installed. A depth of 25 ft. has been reached and the shaft will be continued another 275 ft. Development is also being carried on in the drift-level. Two shifts are now being employed and a third will be added when the machinery is installed.

Kingman.—High-grade gold-silver ore has been opened on the Old Dad property situated two miles north of Hibernia in the Wallapai mountains. A. L. Runyan and associates are driving a tunnel and sinking a shaft on one of the several veins which traverse the claims.—Ore running as high as 289 oz. silver and \$8 gold per ton has been opened in the Old Occident mine at White Hills.

Tucson.—The Yellow Bird Silver Mining Co. has been incorporated to operate the Lincoln group of claims situated 30 miles south-west of here. An adit, which will be run, is expected to tap the Providencia vein system at a point 250 ft. from the portal. The surface indications are said to be promising.

CALIFORNIA

Bridgeport.—A company, capitalized at \$150,000, has been formed to establish a plant on Mono lake to extract the mineral salts from the water. The company is incorporated by W. S. Wentworth of Alameda, George C. Holbrook of San Francisco, and Leonard E. Wing of Sacramento. Utilization of the mineral salts in the Mono lake water has been discussed for half a century, it being known that they formed a valuable washing powder, and could be used as the base for shampoos and other cleansing preparations.

Chico.—According to J. A. Wisebaum, head of the Evening Star company, a fair recovery of platinum has been made by cleaning the sluice-boxes after a recent run. A prospector in the vicinity has also found platinum on Little Butte creek three miles south of Magalia on what is said to be the same channel as that being worked by the Evening Star company.

Downsville.—A road has been built for transporting by auto-truck the ores from the Wheeler Extension to the Hughes & Cameron mill. If operations are successful the mill will be moved to the mine.

Grass Valley.—The North Star company has resumed operation of its plant at full capacity. According to Arthur Foote, superintendent, 60 stamps are crushing medium-grade ore; 400 men are employed by the company.—Eighty stamps are dropping regularly at the Empire mill.

At the Idaho-Maryland mine, being re-opened by the Metals Exploration Co., the 600-ft. level has been placed in condition for mining. Mules have been purchased to do the hauling on the 1000-ft. level.

Randsburg.—John M. Fox, superintendent of the California Rand Silver mine, reports that the south drift on the 450-ft. level has improved in grade, the ore now being shipped. Stopes 913 and 450 continue to produce their customary amount of shipping ore. Stopping will shortly start above the 450 south drift, east of raise No. 914. Plans have been made for the building of a reserve of mill-ore in shrinkage stopes. This work has been hampered somewhat by lack of compressor capacity; with the installation of the new compressor ordered some time ago, additional stopping machines will be put into service and will relieve this shortage. The new working shaft has a total depth of 395 ft. The water shaft at Indian well has a total depth of 184 ft.

Mill construction is proceeding satisfactorily, the arrival of machinery is expected daily.

A number of options have been given on good looking prospects in the silver 'zone'. The sinking on the Silver King, near the north line of the California Rand Silver, continues; also on the Flat Tire group, farther north. Owners of the Capitola group will soon be operating, according to reports. At the North Rand Silver, the collar for the 70 shaft has been placed.

Sonora.—The boarding house at the Belmont Shawmut mine was recently destroyed by fire. Its construction will be hastened in anticipation of resuming operations in the mine and mills.

West Point.—The Lone Star Keltz mines are being operated by the West Point Consolidated Mines Co., of which J. B. Statler is superintendent. Within the last four months complete new equipment has been installed at the Lone Star shaft.

COLORADO

Aspen.—The Silver Mines Co. of America has temporarily closed the Hunter Creek mill for the installation of equipment for use of the 'so-called' Brown flotation process. The Cowenhoven tunnel is being placed in shape for transportation of ores from properties acquired along the line of the tunnel; these now are being developed.

Bonanza.—The Baltimore Leasing Co. has opened a strong and rich orebody on the Baltimore claim and the third car-load shipment is now at the smelter.—The Liberty Bell, fully equipped and with ore in sight, has recently been sold to Missouri people by W. R. Benzle of Denver. Shipments made from the property show net returns of \$132 per ton, chiefly silver.

Boulder.—The milling plant at the Yellow Bird mine is being repaired preparatory to continuous operation this winter. Nineteen sets of lessees are working in ore at the mine; dump ore will also be treated.—The electrolytic plant at the Telegraph mine at Ward has resumed treatment and will be kept in operation until such time as the mine closes down for the winter.

Breckenridge.—The Boyce brothers are preparing a shipment from their recent surface discovery on the June Bug, to be consigned to the A. V. smelter at Leadville. The average silver content is around 500 oz. per ton.—A new vein recently uncovered on the Little Billie, in French gulch, is rich in gold and silver, with a fair lead-zinc content.—A steam-hoist has been installed on the Ground Hog group in Cumberland gulch preparatory to sinking an incline on the wide tale vein, opened by the Davis tunnel. The tale pans free gold.—Progress is reported with the prospecting cross-cut at the 300-ft. level of the 'deep shaft' by the Tymos Mining Co., the object of which is to explore the Ground Hog and Brooks-Snyder estates at depth.

Central City.—Ore opened in sinking a shaft on the Lone Star No. 2, at Hughesville, is reported as assaying 317 oz. silver per ton. The streak is from 4 to 6 in. wide. A pocket at 12 ft. yielded 600 lb. that returned 1100 oz. per ton from the smelter.

Colorado Springs.—Local mining men, owning interests in the Ramona lode claim at Cripple Creek have organized the Ramona Mill Co. and plan development of this old-time producer, now being operated by lessees. Ore sampling \$80 to \$150 gold, with some silver, has been opened on the Alpha and Omega, adjoining the Caledonia mine on the southern slope of Gold hill. The Caledonia, sold by the late W. S. Stratton to a British syndicate, was sold for taxes and debts and is now owned by a Denver man named Doran. The Alpha and Omega is owned by the Dig Gold Mining Co., but is operated under lease.

The Ajax Mines Leasing Co. has commenced shipments

from the Ajax mine on Battle mountain. Twelve sets of sub-lessees are reported working in ore.—Diamond-drills are in operation at the fourth level of the Cresson mine, and the core is reported showing strong 'mineralization'.

Georgetown.—Lessees in the Capital tunnel have opened high-grade copper ore on the Aetna vein and are preparing a shipment.—Work has been discontinued in the Smith tunnel by the Palisade company, and work has been started in the Wilcox tunnel to undercut the orebody recently cut in the Smith tunnel workings. The Burleigh mill is turning out a car of concentrate weekly.

Ouray.—The Hidden Treasure Mines Co. has acquired buildings at the portal of the lower tunnel formerly used by the Camp Bird company and surface rights to the land on which they stand. The new mill of the company of 50-ton capacity is nearing completion and a tram from mine to mill is constructed.—The force at the Atlas mine has been increased to nearly 100; production has been increased.

Pitkin.—A contract has been let for a 100-ft. extension of the tunnel on the Harbaugh group on Gold hill, to cut veins exposed at surface and in an upper tunnel; these produced \$80 gold-silver ore, when last operated several years ago.

IDAHO

Coeur d'Alene.—The Pine Creek Mining Co. has followed the ore for 100 ft. and cross-cut it for 18 ft. About four feet of the vein matter on the foot-wall side is of a high grade and the remainder of the vein-filling is a milling ore. A drift is proceeding on the foot-wall streak, assays from which show 15.2% lead, 5.6 oz. silver per ton, and 7% zinc, while hand-samples of the mill-ore show 14.1% lead, 3.2 oz. silver, and 2.4% zinc. The outcrop of the vein consists of an iron-carbonate cap at least 30 ft. wide and extending 1000 ft. ahead of the present face of the adit. A depth of 750 ft. will be attained by the adit in following the vein. A compressor plant will be installed.

MICHIGAN

Houghton.—Investigators who have completed an industrial survey of the Lake district have come to the conclusion that from the standpoint of the mining companies the local fabrication of semi-finished copper and brass products is advisable. It is held that very appreciable savings can be effected thereby and that it is the only feasible way for the producers to advertise copper and themselves reap the benefits of an increased demand. A diversification of industries for community benefit is recommended. The survey was authorized by the counties of Houghton, Keweenaw, and Baraga. Whether it will bring about any change in policy on the part of the mining companies is solely a matter of conjecture at this time.

Further development of the Gratiot branch of the Seneca property will be watched with interest at the Lake. No. 2 shaft has opened rich ground from the 11th and 13th levels and the decision to sink to a depth of 4000 ft. to connect with the 3rd level of Seneca will prove up Gratiot ground at depth and reveal the character of the Kearsarge lode in the extensive territory between the two shafts. The Gratiot shaft has been kept free of water and sinking can be resumed as soon as the new hoist is installed. The work will be pushed throughout the winter.

According to data prepared for the unemployment conference in Washington, only 16% of the copper mines of the Lake district active in normal years are now working and only 13% of the men are employed. There are 87 mines in the district; 42 of these work when conditions are normal, and only 7 are now operating. In 1916, a normal year, 17,900 men were employed; today the number at work is 2327. The operating mines are Copper Range, Quincy, Mohawk, Wolverine, Seneca, Mayflower, and Arcadian. The

first four are producers while the other three are in the development class.

Of the 239 iron mines in Michigan and Wisconsin, of which 121 work normally, but 21 are producing.

Directors of Arcadian Consolidated have declared an assessment of 50c. per share, payable October 15. There remain in the treasury 43,630 shares of capital stock but it has been decided to retain this for future financing when conditions shall have become more favorable. A statement to shareholders says that development work in the New Baltic shaft has shown persistent mineralization.

MONTANA

Butte.—Lessees in the Walkerville district are producing good silver ore. J. W. Dailey has shipped sorted ore assaying 500 oz. silver per ton. His claims are on the south side of Oro Fino gulch. Kelsey & James have sunk a 126-ft. shaft where they cut a 3-ft. vein of ore averaging 75 oz. per ton. John Conway has good ore on the Glengarry claim.

NEVADA

Argentite.—The Natural Soda Products Co. is to build a mill at the Frances silver mine next year, according to F. H. Taylor, in charge of the property. The company employs 23 men at Argentite, according to Taylor, and there are 60 men in all working in the district. Among those developing claims owned by them or leasing on the Frances are Fred Mechlin of the Nevada-California Power Co., E. Marks, Tonopah and Goldfield merchant; Judge Ray, who has been prominent in Nevada districts since the days of Rhyolite; Ralph Paget, owner of the 5000-acre Butler ranch in Owens valley; the Cleary brothers of Silver Peak; Richard Raycraft of Tonopah; the Inmans of Silver Peak; Jud Collins, cattleman; John Shirley of Silver Peak; William Pagenkopf of Goldfield; W. T. Mitte of Goldfield; Bert Brown of Tonopah; James Edgar, Ernest Shirley, Bert Shiveley, Robert Neil, and Joseph McIvar. There is exposed on the surface of the Paget claims, one mile east of the Frances, a 27-ft. width of \$14 ore. A shaft is being sunk in this ore and the bottom is in a 5-ft. width of \$60 ore. Ernest Shirley and James Edgar have claims adjoining the Frances on the north, south, and east, and they have ore in several places. Shiveley and Neil have a full face of \$37 gold ore in a cross-cut from a drift tunnel. This is the only gold ore found in the district. The vein is 50 ft. wide. Seven men are working on the Frances in prospecting the recent find of 1500-oz. ore 2250 ft. south of the main shaft and tunnel and on the strike of the vein.

Cuprite.—A 50-hp. engine and three-drill compressor are being erected at the 475-ft. shaft on the George S. claim of the Milwaukee group. There is exposed in a 6-ft. vein on the 475-ft. level an 8-in. width of ore assaying \$56 in gold and 14 oz. silver. The 25-hp. hoist now at the shaft on the George S. will be moved to a 100-ft. shaft on the Walter E. claim and the latter shaft will be sunk to 400 ft. Recent finds in the nearby Hornsilver districts have resulted in a revival of interest in Cuprite.

Divide.—The shaft of the Tonopah Divide has been sunk 45 ft. from the 1000-ft. level. Shipments are being made at a rate of 5 tons daily, the ore coming from the 200 and 800-ft. levels.

Malay.—A pump and a new hoist have been installed by the Majuba Fresno Silver Co., whose mine is 17 miles west of here. The last 44 ft. of an 84-ft. shaft is entirely in ore. Four cars have been shipped to Salt Lake Valley smelters that average \$89 per ton.

Luning.—A small shipment of ore assaying 400 oz. silver has been hauled here from a prospect near the camp of Lucknow, nine miles north near the Rawhide road. An option on the property has been taken by Dr. F. E. Bass, of San Francisco, who paid the owners \$1000 as first payment on a total

of \$10,000. The ore has been stripped for 75 ft. on the surface.

Mina.—The West End Con. Mining Co. has taken possession of the Mabel group of claims in the Garfield district, west of Mina in Mineral county, which it purchased lately, and has secured an option from J. H. Miller and L. K. Gregory on the old Garfield mine adjoining. The Garfield mine produced \$6,000,000 in high-grade silver ore when operated by an English company in the early '80s. It was never prospected below the main adit-level. The owners of the Mabel group have shipped \$25,000 worth of ore from shallow workings. The West End is installing a compressor and will sink a shaft, first raising to surface from a shallow tunnel.

Pioche.—Dr. Walter Harvey Weed has issued a report on the Virginia Louise in which he estimates that the mine contains 1,318,750 tons of possible ore, not including that on the 833-ft. level or the zinc ore found by diamond-drilling. He recommends that the blocking out of ore be continued so that the company can make long-term contracts with smelters, or contract with a smelting company to work the mine and treat the ore on a royalty basis.

Rand.—High-grade ore has been exposed by a winze below the 150-ft. level of the Nevada Rand property, 15 miles east of Walker lake. W. V. Rudderow, the manager, says that men developing the property under contract have opened ore on the 200-ft. level assaying \$100 per ton and from the seam of high-grade found in the winze, varying from 6 to 14 in. wide, they have taken 100 sacks of ore assaying \$500 per ton. Samples of the first 50 sacks assayed 8.32 oz. gold and 550 oz. silver, or \$722 per ton. Samples showing hornsilver assayed \$1305 per ton. Ten tons from the winze will be shipped to the sampler of the Western Ore Purchasing Co. at Hazen.

Reno.—At a meeting of directors of the Eureka-Hamilton Mining Co., held in Reno last week, five offers for control of the company were considered and the board decided to reject the offer of the Tonopah Mining Co. W. H. Blackburn, manager for the Tonopah Mining Co., spent a week recently in sampling the property, situated at Hamilton, in White Pine county, and adjoining the once-famous Eberhardt mine on Treasure hill. Cyanide tests on the ore, made at Tonopah, indicate an extraction of over 90%.—The mining committee of the Reno Chamber of Commerce and members of the Nevada Mine Operators Association are studying the mining bill (H. R. 7736) now before Congress, and a concerted effort will be made to bring about its defeat. The bill seems to be generally regarded in the mining region as a serious menace to the industry.

Rochester.—Bullion worth \$60,729 was shipped by the Rochester Silver Corporation, the result of its August operations. The bullion contained 45,083 oz. silver and 756.98 oz. gold. The mill treated 5271 tons. Development work for the month was 516 ft. The balance sheet showed net assets of \$272,870. A dividend of 2½c. was paid on September 20.

Unionville.—The Universal Silver Mines Co. is developing a 2-ft. vein of \$50 ore on the 1200-ft. level.—The Sierra Silver Mines Corporation is said to have uncovered a shoot of rich ore midway between the north and south contact veins.

Virginia City.—At the mill-site of the United Comstock Mines Co. in American Flat a number of large buildings are nearly complete and the first cottages for workmen are being erected. Concrete is being poured at the rate of 125 yards daily in the forms at the fine crushing plant and 12,000 yd. of concrete will be used. The mill-buildings will cover an area of five acres.—The Scheels inclined shaft of the Comstock Silver Mining Co. is being equipped with a small electric hoist. Work in this ground continues to expose ore of

good mill-grade. Old workings of the Pittsburg Comstock Mining Co. have been stripped by William Sharp, who has been retained as consulting engineer for the company. His report shows mill ore for substantial widths at a number of points in the two tunnels and in surface workings.

UTAH

American Fork.—The Pittsburg Mining Co. is reported to have placed an order for an aerial tramway from its mine to the Pacific mill, a distance of 1.4 miles. An order has also been placed for 30,000 ft. of heavy timbers for the towers. It is expected that the tramway will be in operation before winter sets in.

Bingham.—The Montana-Bingham Mining Co. is one of the three mines now operating here; 70 men are employed. Imer Pett, manager, states that an average output of about

Hauling Ore from the Premier Mine in British Columbia

100 tons per day of low-grade copper, with a high excess of iron, is being produced and shipped to the Garfield smelter. Recent development work has opened some ore of high grade.

Eureka.—Directors of the Tintic Standard Mining Co., at their meeting on September 20, voted to pass the third quarterly dividend, which ordinarily would have been paid on September 30. During the first and second quarters of the present year a dividend of 5c. per share was paid. Last year dividend disbursements totaled 40c. per share. E. J. Raddatz, president of the company, stated that the directors felt that, in view of unusual conditions prevailing which tend to reduce the profit of mining operations, it was deemed advisable to omit the third quarterly dividend for 1921.

Shipments for the week ending September 17 totaled 158

cars, as against 137 cars for the preceding week. The Tintic Standard shipped 45 cars; Chief Consolidated, 35; Victoria, 12; Eagle & Blue Bell, 11; Dragon, 10; Iron King, 9; Iron Blossom, 8; Centennial-Eureka, 5; Mammoth, 5; Swansea, 5; Bullion Beck, 4; Sunbeam, 3; Gemini, 3; Colorado, 3; Alaska, 2; Tintic Drain Tunnel, 1.

Logan.—Last June a company known as the Silver Tip Gold & Silver Mining Co. was organized to develop claims 30 miles north of Kelton, a station on the Southern Pacific railway. An incline was sunk on an outcrop which showed \$35 per ton. At a depth of 50 ft., an average sample gave returns of 1.4 oz. gold, 71 oz. silver, and 3.31% copper. At a depth of 80 ft., the ore had a width of 2 to 3 ft., 20 in. of which gave returns of \$110 per ton. A small streak assayed 44.2 oz. gold and 351 oz. silver, or about \$1235 per ton. J. R. Jones will continue development during the winter.

Ophir.—After years of inactivity, other than a small amount of work done by lessees at various times, announcement is made that the Eureka-Ophir property will be re-opened on company account. J. W. Cairns will be manager of the property. The buildings at the mine have been repaired, a 25-hp. gasoline-hoist and compressor purchased, and supplies laid in for development during the coming winter. The property has been opened by a shaft to a depth of 400 ft. Above that level, it is said, about \$175,000 worth of silver and lead has been extracted, while lessees have paid \$11,000 in royalties.

Park City.—Owing to improved labor conditions, much exploratory work is being done at the various Judge properties, according to G. W. Lambourne, general manager. In a raise from the 900-ft. level at the old Judge mine, in the middle vein system, a new ore deposit of promise is being developed. The raise is now up 150 ft. from the 900-ft. level, and for the last 40 ft. has been in ore averaging 35 oz. silver and 35% lead, with a width of from 4 to 5 ft. In the Park-Utah property, work has been carried on from the Ontario lower drain tunnel, which is owned jointly by the Ontario and Judge companies. Approximately 8000 ft. from the portal a cross-cut to prospect the important fissures of the Park-Utah property was started. Several shoots of high-grade ore have been intersected by this cross-cut, which is called, temporarily, the 1800-ft. level. One of these shoots has been followed on the strike of the vein for a distance of 300 ft. Cross-cuts run at intervals of 60 ft., according to Mr. Lambourne, prove that the shoot has a width of from 5 to 27 ft. of shipping ore.

Ore shipments for the week ending September 17 totaled 1913 tons, of which the Silver King Coalition shipped 713; Judge companies, 548; Ontario, 412; and the Naildriver, 149. Shipments the previous week totaled 1354 tons.

WASHINGTON

Colville.—The Old Dominion mine in Stevens county is the scene of a discovery of exceptionally rich silver-bearing ore. According to reports the ore contains 1140 oz. of silver per ton, which is equivalent to \$1140 per ton at the fixed quotation of \$1 per ounce. It lies in a body 3 ft. wide. The find was made at a depth of 600 ft. in a tunnel driven 2150 ft. The grade is said to persist for the short distance the ore has been followed by the drift. W. H. Linney is president and general manager.

Northport.—Five or six boulders of lead, like those found in the Electric Point and Gladstone Mountain mines, have been met in sinking to a depth of 56 ft. in the property of the Keystone Lead Mining Co. in the Electric Point district. The shaft will be continued to a depth of 100 ft., where drifting will be started.

BRITISH COLUMBIA

Allice Arm.—Another strike has been made at the Belle-

vue mine, Illiance river. The lode is 1 to 3 ft. wide and composed almost entirely of fine-grained galena. It has been traced on the surface for 300 feet.

Cranbrook.—F. W. Beatty, president of the C. P. R., of which the Consolidated M. & S. Co. is a subsidiary, paid a visit to the Sullivan mine recently and to the company's power-plant, at Bonnington Falls. It is rumored that Mr. Beatty's visit is in connection with the erection of the first 2500-ton unit of the new concentrator at the mine, for which it is stated the Consolidated is proposing to borrow \$5,000,000.

Hope.—Edwin T. Hodge, consulting engineer for the Liberator Mining Co., furnishes the following information about the Emancipation mine, which the company is operating. As a result of the work that has been carried on continuously for the past 15 months, 5000 tons of ore, averaging \$20 per ton, has been blocked out on the two-foot vein, and 1000 tons, averaging \$30 per ton, has been extracted. On the surface this vein has been stripped for 2000 ft. The ore in sight in both the large and small veins warrants the erection of a 50-ton plant. This mill will be built at the railway track, 2700 ft. from the mine, and will consist of a crusher, ball-mill, plates, classifier, pebble-mill, and cyanide tanks. It should be completed in 60 days.

Nelson.—The Nugget Gold Mines, Ltd., has re-started its mill, which has been closed for the last few weeks owing to a shortage of water. The mine is developing well; a profit of some \$9000 being made in July, before the shut-down.

—J. B. Smith, president of Silversmith Mines, Ltd., has bonded the Bayonne group, at the head of Summit creek and about 12 miles over the summit from the Nugget mine. Supplies have been taken to the property, and development will be continued through the winter. This property is owned by James Gerrard, formerly U. S. Ambassador to Germany, and Thomas Hickey, of Butte.—The Reno group, in the Sheep Creek district, is said to be developing well. There are five veins on the property, ranging from 2 to 4 ft. wide and averaging in the vicinity of \$20 per ton. A tunnel being driven on No. 1 vein will give 550 ft. of ore overhead. This vein is 3 ft. wide and in places runs over \$100 per ton in gold. Work is to be continued through the winter.—After seven months of exploration, R. A. Grimes has succeeded in picking up the continuation of the ore-shoot on the other side of the fault at the McAllister. The shoot has 4 ft. of good shipping ore on the hanging wall.

New Hazelton.—A trial shipment of ore from the Harvey group, in the Babines, which was sent to the Tacoma smelter, gave a return of \$316.39 per ton. The property is owned by the Balkis Mining Co., an Edmonton concern.

MEXICO

Durango.—Edward C. Bryan and Luis G. Gavaldon have re-located the La Rueda Minera mines, consisting of 15 claims, situated in the Villa Ocampo district. These properties were declared forfeited for non-payment of mining tax. They are being re-surveyed by Robert C. Colwell.

The smelting plant of the Penoles Mining Co. at Mapimi is being partly dismantled and the equipment moved to the Torreon smelter, which is owned by the same company. Work is being carried on at some of the principal mines of the company in the Mapimi district on a reduced scale, while the smelters at Torreon and Mapimi are closed for the change. The Penoles company also owns the San Toy, Inglaterra, and other mines in the Santa Eulalia district of the State of Chihuahua and is shipping its ores to the Avalos smelter, owned by the American Smelting & Refining Co., and situated a few miles from Chihuahua City.

P. W. Martinez has taken up some gold and silver properties in the Topla district west of Durango City. One of the new groups comprises three pertenencias to be patented under the name of Cuatro de Julio.

Chihuahua.—Charles Ballow, representing George Johnston and Albert H. Davidson, is opening up the Santa Rita and Santa Barbarita mines, in the Santa Barbara camp, municipality of Guazapares, in this State. The properties are situated near La Judia and Marco Antonio gold-silver mines. There are a number of old workings on the Santa Rita and Santa Barbarita, which will be cleaned out and sunk to a greater depth.—A 1000-ft. tunnel shortly is to be run on the Erupeion Mining Co.'s property in Los Lamentos mountains, east of Villa Ahumada. As development work on these properties continues, larger bodies of ore are exposed.

Stiles & Escobar, operating the Dolores mines in the Santa Eulalia district, have recently purchased the Continente mine, which they will operate in connection with their other properties. They expect shortly to begin the construction of a new concentrating plant of 50 tons daily capacity for treating their ores on the ground.

ONTARIO

Cobalt.—The outlook for the silver-mining industry has been improved by the increase in the price of silver, which has given a decided stimulus to the activity of the producing mines. The less important properties which remain closed are now in a position where resumption of work is possible. Shipments of ore last week were the largest for several months past, amounting to 313,095 lb., the O'Brien heading the list with 142,000. The Nipissing and Mining Corporation are confining their shipments to bullion.

Kirkland Lake.—Good results are being obtained at the Teck Hughes, where, according to an official statement, the mill treated an average of 88 tons of ore every 24 hours during the first six months of the year with a recovery of \$10.34 per ton. The work for increasing the capacity of the mill to 150 tons per day is under way.

Official figures for the months of May and June show that the Wright-Hargreaves recovered \$12.69 from each ton of ore treated. The mill is now handling an average of about 130 tons per day.

During the first half of 1921 the mill of the Kirkland Lake treated an average of approximately 125 tons of ore daily. Some difficulties were encountered in getting out the ore, operations having been hampered by a rock-slide, and the average recovery was below normal, being \$4.90 per ton. The company has announced a wage reduction of about 15%.

Porcupine.—The enlarging of the McIntyre mill is progressing slowly owing to time required to determine the method best suited to deal with the carbonaceous ores from the lower workings. Some of the machinery is already on the ground.

The Allied Porcupine has now unwatered the shaft and workings of the Three Nations mine down to the 200-ft. level.

Rankin Township.—A staking boom has taken place in this locality, situated about 20 miles north-east from Gowganda, following a discovery of gold by Bernard Mlemac, an Indian, who brought out samples which started a rush of prospectors. About 50 claims have been staked. The gold is stated to occur in schist which shows but little quartz, the outcropping formation being about a mile wide from east to west and less than two miles from north to south.

South Lorrain.—High-grade ore has been found at a depth of 330 ft. on the Haileybury Frontier property. The vein is apparently important. The mine was re-opened last year with the object of taking out cobalt ore, but attention has lately been devoted to mining silver.

Developments at the lower levels of the Keeley are encouraging. The stamp-mill is operating on medium-grade ore and turning out concentrates containing approximately 1800 oz. silver per ton.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Augustus Locke was at Boston recently.

Norman C. Stiles is here from New York.

William T. MacDonald is at Blackfoot, Idaho.

Abbot A. Hanks has returned from New York.

Howard D. Smith was at Los Angeles last week.

George H. Garvey is geologizing at Telluride, Colorado.

Louis S. Cates has returned to Salt Lake City from Boston.

T. H. Jenks, of Los Angeles, is near Mazatlan, in Sinaloa, Mexico.

James A. Kaney has returned to San Francisco from Kantishna, Alaska.

G. B. Hogenraad has returned to Amsterdam, Holland, from Padang, Sumatra.

W. F. B. Berger has opened an office as consulting engineer at 120 Broadway, New York.

Frederick W. Denton has moved from Painesdale, Michigan, to Cambridge, Massachusetts.

Robert Marsh, Jr., is at Salt Lake City. He returned recently from Alaska and British Columbia.

W. R. Appleby, Dean of the Minnesota School of Mines, has returned to Minneapolis from Manchuria.

Jay A. Carpenter has been appointed Professor of Mining in the South Dakota School of Mines at Rapid City.

O. R. Whitaker has returned to Denver from a four months trip in Mexico, where he has re-opened the old Mapimi mines.

E. W. Bullard has returned from New York. While at St. Louis he officiated as judge in the international mine-rescue contest.

Raymond Brooks is at Musonol, in the Belgian Congo, as manager for the western mines of the Union Minière du Haut Katanga.

J. R. Elliott, of Pittsburgh, Pennsylvania, president of the Three Kings Mining Co. at Park City, Utah, has been visiting the mine.

Alan M. Bateman, of the Department of Economic Geology of Yale University, has returned to New Haven from professional work in Alaska.

H. C. Gardiner, of the staff of the Anaconda Copper Mining Co. at Butte, spent several days at the International smelter at Tooele recently.

Paul Hilsdale, mining engineer of Salt Lake City and Eureka, Utah, has returned to Utah after a three months trip to islands in the South Pacific.

H. Foster Babo, Director of the U. S. Bureau of Mines, will be tendered a dinner by the local section of the A. I. M. & M. E. on Tuesday, October 4, at the Engineers Club, in San Francisco.

Neal N. Googlein has resigned as chief assayer to the Chihuahua plant of the American Smelting & Refining Co., and has established an assay office at Chihuahua, where he will represent ore-shippers.

George H. Heath, formerly chief chemist for Calumet & Hecla; R. R. Seiber, formerly manager of the Winona mine in the Lake Superior copper district; and W. C. Polkinghorne, superintendent of the Ahmeek mill at the time of its suspension, have joined the faculty of the Michigan College of Mines at Houghton.

Charles J. Lavelle, for the past five years in charge of the tabulating department of the Utah Copper Co. at Garfield, Utah, has resigned. He will sail from New York on the 'Carmania' on October 8 for Southampton, on his way to the Belgian Congo to accept a similar position with the Union Minière du Haut Katanga.

THE METAL MARKET

METAL PRICES

San Francisco, September 27

Zinc, slab, cents per pound.....	6
Zinc-dust, cents per pound.....	9

EASTERN METAL MARKET

(By wire from New York)

September 26.—Copper is inactive but steady. Lead is active and higher. Zinc is in better demand, and advancing.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MINTS ARE COINING SILVER DOLLARS AT A RECORD RATE

During August the mints of the United States coined 11,870,000 standard silver dollars under the provisions of the Pittman Act, bringing the stock on September 1 to 303,739,326. Since the latter part of February 1921, when coinage of dollars was resumed, there has been minted a total of 33,993,900.

The three mints, at Philadelphia, San Francisco, and Denver, are coining dollars almost exclusively, working 24 hours per day, with three shifts of eight hours each. There is no demand for subsidiary coins at present, in fact money is still flowing back into the Treasury, so the facilities of the Mint service are being devoted to reducing the large stock of silver bullion on hand, purchased under the Pittman Act, which on September 1 amounted to \$53,083,229.

Including silver dollars which were melted to provide bullion for subsidiary coinage, a total of 270,121,554 dollars was melted under the Pittman Act. On April 1, 1918, before the melting process began, the stock of standard silver dollars numbered 568,269,513. Deducting from this total the number melted, or 270,121,554, would leave a balance of 298,147,959. On February 1, 1921, when coinage operations were resumed, the stock of silver dollars was down to 269,746,326, which indicates that the stock has been reduced by 28,401,633 dollars, apart from the operations under the Pittman Act. This difference represents silver dollars which were shipped to the Orient at a time when the price of silver was soaring and when it threatened to go beyond the coinage value of subsidiary silver, which is \$1.38 plus per ounce. At that time the Treasury, acting in co-operation with the Federal Reserve Board and the Reserve banks, arranged to release silver dollars to be employed in regulating our exchanges with countries having a silver monetary standard.

About 13,000,000 dollars went to the Orient under these arrangements, while, altogether, the silver dollars leaving the country from November 1918 to May 1920 approximated 29,000,000. As these dollars were not melted under the Pittman Act they do not have to be re-coined, so that the silver-dollar stock will be at a less total, even after the operations under the Pittman Act are completed.

The increase in silver dollars since coinage operations were resumed is shown as follows:

	Stock	Increase over preceding month
September 1	303,739,326	11,870,000
August 1	291,869,326	4,647,000
July 1	287,222,326	3,080,000
June 1	284,142,326	7,660,000
May 1	276,482,326	4,370,000
April 1	272,112,326	2,310,000
March 1	269,802,326	56,000
February 1	269,746,326

The Treasury has purchased to date 72,700,430 oz. of silver out of the 208,000,000 oz. to be purchased under the Pittman Act.

MONEY AND EXCHANGE

Foreign quotations on September 27 are as follows:

Sterling, dollars: Cable	3.74
Demand	3.74 1/2
Franc, cents: Cable	7.10
Demand	7.21
Lira, cents: Demand	4.10
Mark, cents	0.85

Eastern Metal Market

New York, September 21.

General conditions are changed but little, and while optimism is the rule, heavy buying does not yet materialize.

The copper market continues to be a disappointment with demand very light.

Buying of tin is fairly good from all sources with prices steady.

The lead market is moderately active and strong.

There is still little life to the zinc market.

Antimony is dull and unchanged.

IRON AND STEEL

The steel trade recognizes the good effect of the stir in the wire trade connected with the recent price advance, and on a smaller scale the sheet market has had some notice in the past week, says 'The Iron Age'. Three or four independent companies have announced an advance of \$5 per ton. It is not yet clear how far this will be followed. The Steel Corporation has made no change though it is expected to do so, and thus far the chief effect has been to give a few mills more sheet orders at their former prices than they have had in some weeks.

The larger contribution that the lighter products—wire, sheets, and tin plates—are making to current mill-operations is emphasized by a further slight increase in total steel output, as expressed in ingots, at the same time that the heavier products—rails, plates, structural shapes, and bars—show on the whole no increase.

A gradual increase in the buying of steel, even though actual consumption may not change in any marked degree, is a common expectation for the autumn months, but buying for forward delivery is not looked for until 1922. Meanwhile there is a definite effort by steel manufacturers to limit their losses on current business.

Structural steel lettings, which at times seem to be increasing, are shown to have been fairly uniform for six months ending with August. The August total was 59,300 tons, or about one-third of a month's fabricating capacity, while the six months' average was 57,550 tons.

Exports of iron and steel for August are estimated at 73,792 tons, apart from several unimportant items unreported. This is the lowest tonnage since January 1909, and compares with 86,523 tons in July 1919 and 431,484 tons in August 1920.

ANTIMONY

The market is featureless with quotations nominal at 4.45c. per pound, duty paid, New York, for wholesale lots for early delivery. Jobbing lots are quoted at 4.65 to 4.90c.

ALUMINUM

Virgin metal, 98 to 99% pure, is unchanged at 24.50c., f.o.b. plant, from the leading producer, with the same grade available from importers at 19 to 20c., New York.

COPPER

Disappointment as to buying power or demand continues the feature of this market. Prices are not weak and are firmer if anything. Consumers, however, continue to refrain from buying, believing that the present advance has been overdone and that they can buy at less prices later. Electrolytic copper is quoted by those willing to quote, at 12.12½c., New York, or 12.37½c., delivered, but these prices are largely nominal. It is said that 12.25c., delivered, could be done but there has been no actual test of the market. Several large sellers continue out of the market. It is generally the opinion that all the cheap copper has been eliminated perma-

nently, or at least so far as the near future is concerned, and hence the stiffer conditions of prices. Foreign buying is dominated by the Far East, but it is not large in the aggregate, due to exchange conditions.

LEAD

There is more strength in the lead market than in any other. Buying is active and prices continue to advance. Late yesterday the American Smelting & Refining Co. added more points to its prices, bringing it to 4.65c., New York and St. Louis. A feature of the market is buying from consumers who have not been heard from in a long period. The outside market is strong at 4.65c., New York, and 4.45c., St. Louis, but not much selling is reported by independents in the market, the demand being apparently satisfied by the leading interest.

TIN

Moderately active buying of Straits tin continues a feature of the market. Last week Wednesday about 200 tons of futures was sold at 26.50 to 26.62½c. and on the following day probably 200 to 300 tons was sold at 26.37½ to 26.50c., purchased nearly equally by consumers and dealers. On Friday there were light sales of futures at 26.25c. and the same is true of Monday of this week when October-November shipment from the East sold at 26.37½c. with 26.50c. bid at the close. It is reported that consuming inquiry has been good most of the time. Spot Straits tin was quoted yesterday at 26.50c., New York, while the London market values were about £1 per ton lower than a week ago at £155 10s. for spot standard, £157 15s. for future standard, and £156 5s. for spot Straits. Arrivals thus far this month have been 2225 tons with 3050 tons reported afloat. American pure tin is quoted at 26.12½c. with 99% pure tin at 25.87½c.

ZINC

This market is a little weaker than it was a week ago with prime Western sold down to 4.17½c., St. Louis, in the last week and with unconfirmed rumors that 4.15c. has been done. Inquiry is not active and the greater activity in the steel market, particularly in sheets, has not had its effect yet on zinc. There is a little business being done each day but most producers are not active sellers. We quote the market at 4.17½c., St. Louis, or 4.62½c., New York, for wholesale lots for early or 30-day delivery.

ORES

Tungsten: The market remains lifeless and featureless with values nominally unchanged at \$3 and upward per unit in regular 60% concentrates, depending on the quantity, grade, and delivery.

Ferro-tungsten is inactive and nominal at prevailing prices.

Molybdenum: There is no demand and prices are nominal at 50 to 60c. per pound of MoS₃ in regular concentrates.

Manganese: Demand has completely vanished and quotations are nominal at 20 to 22.50c. per unit, seaboard.

Manganese-Iron Alloys: The market is much more active and more sales have been made than in many weeks. At least 1000 tons of British and American ferro-manganese has been sold on a basis of about \$58.35, seaboard, for both alloys, the new price announced a week ago. Inquiry is also better, one being for 125 tons for early shipment. Spiegel-eisen is inactive and unchanged at \$25 to \$26 for the 20% alloy.

Demand for 50% ferro-silicon is light at \$60 to \$65 per ton, delivered.

HARDWARE		
Anti-friction met.	per pound	0 10
Babbitt gentine	"	0 42 1/2
Brass sheets, half-hard	ft. per pound	0 28
Drill-steel, hollow, first grade	in ton lots, per pound	0 18
"	" solid	0 11
Fish-plate bolts, 5/8 by 2 1/2	per 100 lb.	8 75

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. These, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices, but it should be understood that it is not easy for the producer to market them at this time.

Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per cwt.....	60c
Asbestos (crystalline), according to length of fibre, per ton....	\$20 to \$2500
Barite, white and free of iron (crude), per ton.....	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi.....	12
Feldspar, crude, lump, free of iron, per ton.....	5 to 10
Fluor spar, 85% calcium fluoride, per ton.....	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton.....	5 to 10
Graphite, crystalline, per pound.....	3c. to 7c.
Magnetite, calcined, per ton.....	25 to 35
Manganese ore, less than 0.75% Fe; less than 0% SiO ₂ , per ton	25 to 30
Mica, according to size, clearness, and cleavage, per pound....	1 to 8
Molybdenite, not less than 85%, free of copper, per % MoS ₂ ..	8 to 12
Molybdenite, not less than 85%, free of copper, per % MoS ₂ ..	8 to 15
Ochre, according to strength, crude, per ton.....	8 to 18
Sulphur, 99.5% pure, only trace of As and Se, per ton.....	15 to 18
Talc, lump, white per ton.....	7.50 to 10
Tin ore, not less than 80% Sn, per % Sn.....	5
Tungsten ore, not less than 85% WO ₃ , per % WO ₃	2.75 to 3.00

T. A. RICKARD, . . . Editor

AMONG the few gold-mining regions that are showing a steady increase in production of the precious metal is Southern Rhodesia. The output for July was 51,564 ounces, as compared with 49,466 ounces in June, and with 42,208 ounces in July of last year. Southern Rhodesia is essentially a country of the small-mine owner, whose methods of mining and milling are often sounder, more economical, and more efficient, despite small tonnage and limited capital, than those adopted by the officials of many big corporations.

THE Supreme Court of Nevada has held that failure to file notices of intention to take advantage of the joint resolution of Congress waiving the requirement of annual assessment work does not necessarily impair the rights of claim-holders. Even though the terms of the resolution are mandatory, the construction of the Nevada Court is that a showing of good faith and an open, honest effort to comply with the statute may serve to preserve the right of the owner, even in the absence of formal filing. Although this decision theoretically might work a hardship on some adverse claimants, we are of the opinion that in reality few, if any, re-locations have been made by men who were not aware of the intention of the original holder to comply with the terms of the Act.

INCALCULABLE are the vagaries of human nature. First we were told—and we believed it—that in order to restore normal conditions we must be thrifty, we must work, we must be productive. Now, apparently, the pendulum of opinion has swung, so wildly as to seem drunken, to the other extreme; for “a conference of New York’s leading business men has been called to further the movement for a ‘buyers week’, with the idea of selling a \$100,000,000 worth of merchandise in two weeks, thus starting a flow of goods from factory to consumer, giving relief to the economic pressure and aiding unemployment”. Was ever a bigger bit of impudence perpetrated upon a weary public? The dry-goods merchants who desire to start an orgy of spending under cover of “relief to the economic pressure” are sardonic humorists—and impudent fakers.

DISCUSSION this week starts with an interesting letter on the subject of the proposed new mining law from Mr. Robert B. Brinsmade, who is now in Mexico.

He submits a thoughtful criticism, based on his experience not only in the United States but in the country in which he is sojourning. He is a radical in his views of our social system and speaks plainly concerning such of its anomalies as bear upon the mining industry. Mr. Algernon Del Mar contributes several useful notes on the application of flotation to the concentration of precious metals. He quotes from experience and offers sundry data based upon the operation of two mills. Mr. A. C. Halferdahl writes on surface-tension in flotation, apropos of Mr. Fahrenwald’s recent article. Our friend Mr. Warren D. Smith, now Chief of the Division of Mines in the Philippines, writes to correct a statement, appearing in a consular report and re-printed in a recent issue of the ‘Press’, concerning the silver-ore resources of the Islands.

DAMAGES from the Brotherhood of Railway Trainmen are being claimed by a switchman who is the plaintiff in a suit that has been filed in the District Court at Chattanooga, Tennessee, to recover \$5000. The switchman claims that the Southern Railway was forced by the Brotherhood to dispense with his services. The case is of interest, for if the members of such an organization demand the dismissal of an employee who is not one of them, and if the organization can be sued for damages, then it would appear that the recognition of the principle of the ‘open shop’ is inevitable. In the present case the Brotherhood has filed a plea in abatement, affirming that it is merely a voluntary association, with no officer or agent in the State of Tennessee upon whom the process can be served. The local court, it maintains, is without jurisdiction in this instance. This would appear to us to constitute a legal quibble. We trust that the discharged switchman will be awarded damages in compensation for the deprivation of his right to work, and because of the interference, by a labor organization, with a fundamental privilege of a citizen of this country.

IN the ‘Los Angeles Daily Times’ we read of a local dentist having discovered—near Santa Monica—a deposit “said by some metallurgists to be rock containing refractory carbon”. This deposit is said to constitute “high-grade gold ore”. To recover the gold, it is necessary—we are told—“to bake or roast the shale or rock deposit at a high temperature to burn out the carbon”, that is, the “refractory” carbon. Several high assays

are quoted, but it is admitted that "no efforts have been made to ascertain accurately the percentage of gold content that can be recovered by a commercial process". We venture to say that no effort has been made to write intelligently, to obtain trustworthy data, or to make any reasonable inquiry into this silly tale. The abysmal ignorance and lack of education illustrated by the matter and manner of this piece of writing serve to indicate the kind of foolish persons that work on the daily press. Among the citizens of Los Angeles are many capable mining engineers; indeed, some of them are men of world-wide experience and knowledge. Why does the staff of the 'Times' forego the opportunity of obtaining reliable information and of saving itself from well-deserved ridicule?

AN interesting side-light on 'unemployment' statistics may be found in the experience of a reporter in Denver, who in the course of one morning obtained seven prospective jobs at manual labor, while during the same period he was refused work for various reasons by only six other employers to whom he applied. Government estimates place the number of unemployed in Denver at 8000. According to the article in the 'Rocky Mountain News' the reporter told no tales of a sick wife and starving children; he had no story of service in France as a soldier fighting for his country; he made no effort to play upon the sympathies of the prospective employer, but merely asked for a job on the ground that he was well and strong and willing to do hard work. He dressed himself in workman's clothes and only revealed his identity after having been hired to go to work the next morning at a wage of \$4 or more per day. Even in these times a man can live on \$4 per day. There are, of course, men who are not physically able to work with pick and shovel or to truck heavy freight at a railroad depot, but we wonder if much unemployment is not the direct result of receiving high wages during the War, and 'getting by' with as little work as possible in return. Suppose that every man who was physically able would take the best job that was offered at a living wage. Would it hasten the return of prosperity and thereby enable him to get back his old job at better pay? Prominent labor leaders, employers, and capitalists in conference with Mr. Hoover at Washington will help; but the real solution of unemployment may be a radical change in the attitude of every individual who must work for his living.

TELLURIDE minerals have been found in an orebody recently in a mine on the Comstock lode. This is interesting, chiefly because it raises a difficulty, by no means serious, in the metallurgical treatment of the ore. The discovery is described in the daily press as a "tellurium ore strike"; the find itself is said to be "the largest body of tellurium ore ever found in Nevada", and "the finding of this metal in such an orebody is of unusual significance", because "tellurium is usually associated with high-grade gold ore". It is truly remarkable how much misinformation can be conveyed by an ignor-

ant scribbler. In the first place, he means that telluride ore, not tellurium, has been found. The element tellurium has been found in the mines of Colorado and Transylvania. It is an element—not a metal—of slight value, its principal use being as a violet pigment in the making of stained-glass windows. The tellurides, or compounds of tellurium with the metals, are of much greater economic importance, especially to the miner. The report quoted above must refer to the finding of ore containing the telluride of gold, namely, calaverite, which owes its name to the county of Calaveras, in California, from which came the specimen that the chemist F. A. Genth used to determine this mineral species. As to "the largest body of tellurium ever found in Nevada", we recall the fact that ore rich in the tellurides of gold and silver was exploited in 1907 in the Combination mine, which later became a part of the Goldfield Consolidated, at Goldfield, Nevada. As to the significance of finding a telluride in a gold ore, we venture to say that it is no more significant than the finding of native gold, for veins that carry gold as a telluride are not necessarily richer than those that contain gold in pyrite or in quartz. The characteristic is qualitative, not quantitative. The idea that "tellurium is usually associated with high-grade ore" is opposed to experience in many parts of the world, notably Transylvania, Cripple Creek, and Kalgoorlie, in all of which districts there are veins of low-grade as well as of high-grade telluride ore. It was thought at one time, by newspaper writers and other careless persons, that the presence of a telluride mineral in an ore was a sign of persistence in depth. At Kalgoorlie this fallacy was rampant during the boom of 1897; it was advocated by a pseudo-scientific gentleman named Maryanski, whose sobriquet, "Mary Ann", fitted him admirably. We hope our friends on the Comstock will find plenty of gold, preferably in the native state, readily amenable to cyanidation, without roasting.

South American Affairs

International disputes are generally of so complicated a character and so involved with domestic matters that it is usually inadvisable for the nationals of other countries to proffer advice or to act as arbitrators. Much harm has ensued from the outbursts of irresponsible journalists and editors in this country who occasionally discuss South American affairs, and whose viewpoint seldom is based on reliable information or on a first-hand knowledge of the facts. It will be a matter for regret, both here and in Latin America, that our contemporary in New York has attempted to discuss and to pass judgment on what is known as the Taena-Arica controversy; for it is evident that the writer of the editorial on the subject that appears in a recent issue of the 'Journal' is ignorant of the facts. This territory, we are told, "before the war between Bolivia, Peru, and Chile, was considered Peruvian, but was held of little value, and after the war it was turned over to Chile for 10 years, with the agreement that at the end of that

period a plebescite, or vote of the population, should determine whether it should thenceforth be Chilean or Peruvian". The war, which by the way was one in which Chile fought the combined forces of Peru and Bolivia, resulted in the complete defeat of the allies. Taena and Arica, together with the provinces to the south that belonged formerly to Peru and Bolivia, were won by force of arms. The writer then disseses what he terms the "unsatisfactoriness" that "developed in the plan for the disposal of Taena-Arica. Valuable nitrates were discovered in the province and copper mines were opened; . . . but in the meantime Chile had already apparently disposed of her possible ownership by agreeing that if she obtained, by the plebescite, possession of Taena-Arica, she would sell it to Bolivia so that that landlocked country might have an outlet to the Pacific through the port of Arica. Mark, then," continues our contemporary, "how the discovery of valuable minerals changed all this. Chile becomes reluctant to give up that possession which is nine points of the law, and quite rivals the later example of the Supreme Council in the Upper Silesian matter in her failure to carry out a definite plebescite". This account of the Taena-Arica controversy lacks evidence of familiarity with South American affairs. The treaty between Chile and Bolivia in regard to an outlet on the coast was never ratified; Chile, however, is still willing to help Bolivia in a spirit that is seldom shown to a defeated nation. Her integrity cannot be impugned on the ground that a change of attitude has resulted because of the discovery of valuable minerals; the commercial nitrate deposits and the larger copper mines are far to the south. Nitrate, the more important, was discovered early in the 19th century; the industry was later exploited, developed, and financed by Chileans in the Province of Tarapacá; in the Departments of Tocopilla, Antofagasta, and Taltal, in the Province of Antofagasta; and at Aguas Blancas, a district in the Province of Antofagasta. Taena is, primarily, a buffer province, of little material value and of considerable expense to Chile. Had the writer of the editorial in question examined the available documents he would have been less likely to blame Chile for the failure to carry out the plebescite at the arranged date. Few of our South American friends are guiltless of spreading propaganda in this country in favor of this or that phase of international dispute; in many cases they are obliged to do so in order to combat misinformation. Everyone is entitled to an expression of opinion. We ourselves were taken to task lately, in a letter that we were asked not to publish; but, as the editorial note that was criticized was based on actual experience, personal contact, and first-hand information, we still venture to think that the comments and conclusions merited publication and thoughtful consideration. It is the duty as well as the privilege of an editor to attempt to mold public opinion. In regard to the discussion of the Taena-Arica controversy, however, there is a tendency to overlook the undisputed fact that the nitrate deposits had been exploited by Chileans for many years be-

fore the War of the Pacific—that conflict arose because of an alleged unfairness on the part of Bolivia, the ally of Peru, toward Chileans, particularly toward the *Compañía de Salitres y Ferrocarril de Antofagasta*, a Chilean corporation. Similar circumstances, few of which have led to war, have marked the history of other countries in which, for reasons that need not be discussed, the nationals have failed to exploit their own resources. Further, the development of Chilean copper mines during recent years has occurred in territory the ultimate ownership of which cannot be called into question. The League of Nations has no more right to return the Province of Antofagasta to Bolivia than to give to Great Britain the political control of Massachusetts. The copper mines in the Province of Taena are of negligible importance; there is little indication of workable nitrate deposits there.

Lead-Poisoning

The Treaty of Peace that was signed at Versailles provided for the holding of international conferences on questions in which labor has a vital interest. These conferences are attended by representatives of the governments, of the employers, and of the workers; and each country is under an obligation to carry out, so far as practicable, the decision. The International Labor Office will hold a conference at Geneva this month, under the auspices of the League of Nations, at which proposals will be made to prohibit the use of lead in paints. It is estimated that 85% of the white-lead produced is used in such manufacture, so that the loss to the lead industry would be serious if such a proposal were to be endorsed and enforced. It is unfortunate that labor leaders so often refuse to consider the facts relating to a question, or to accept a scientific explanation of a happening. The lead in paint has been blamed for all the troubles and ailments that afflict the workers in the painting trade; but, as Mr. Stephen Miall pointed out at a meeting of the Society of Chemical Industry in Liverpool recently, the abolition of lead and the substitution of other heavy-mineral derivatives may result only in an aggravation of the trouble. Zinc oxide, one of the proposed substitutes, is not equal to white-lead either in durability or in 'hiding' power; further, it is known to be a general protoplasmic poison, causing muscular paralysis and kidney disease. Many of the ailments that afflict those in the painting trade are due to the turpentine in the paint and not to the lead; in other instances it has been shown that disease results from carelessness. Thus the 'rubbing down' of old lead paint with sand-paper or pumice-stone produces a poisonous dust that may be inhaled by the worker; this practice, as suggested by Mr. Miall, should be prohibited by law; the sand-paper should be moistened with a cheap mineral oil; under such conditions it lasts as long as if used dry, and the results are equally good. Again, painters should never handle dry white-lead or other metallic pigment; these should be supplied in an oil medium. Lead-poisoning is, to a large extent, preventable; this fact is proved easily by statistics. The

number of cases of poisoning in the British white-lead industry was reduced from 399 in 1899 to 189 in 1901, 40 in 1915, 18 in 1916, and none in 1918. These results were obtained after a realization of the fact that "all risk lies in inhalation of dust and fumes. These removed and prevented, there will be no lead-poisoning".

At the first of the conferences of the International Labor Office, held at Washington a few years ago, it was recommended that in view of the complexity of industrial diseases the problems involved should be considered carefully beforehand by a committee, with representatives of the governments, of the employers, and of the workers. No such committee has been appointed; the problems of lead-poisoning are being considered only from the biased viewpoint of the Labor Office. The least that should be expected is that such questions will be discussed with all due regard to scientific fact and historical accuracy. A vigorous propaganda was started in England in the early days of the present century for the abolition of the use of lead in the pottery industry. Instead, the problem was solved by research, followed by the application of the principles of common sense and hygiene; lead-poisoning has been abolished in that industry. We agree with Mr. Miall when he says that "the International Labor Office may be productive of much good, but in so far as industrial hygiene is concerned it will accomplish nothing without the co-operation of those primarily affected; its present methods are tending to promote suspicion rather than confidence".

Minerals Separation v. Butte & Superior

Litigation over the Minerals Separation patent is proceeding in the usual leisurely way. The latest decision in the Butte & Superior case appears to have been misunderstood in some quarters. Several months ago the patent-exploiting company filed a motion in the U. S. District Court of Montana asking that the Master, to whom the case has been referred for an accounting, be instructed to consider only such standards of comparison as were open and available to the defendant at the time (1905) of the invention that is the subject of the suit. This question of a standard arose from the need to estimate the amount of "gains, profits, and advantages" due to the plaintiffs by reason of the adjudged acts of infringement. The plaintiffs, Minerals Separation Limited *et al.*, desired to restrict the defendant, the Butte & Superior Mining Company, to water-gravity concentration as practised in 1905, and thereby to exclude, as a standard of comparison, the '1% +' oil methods that were held by the U. S. Supreme Court to be non-infringing. The defendant, in his brief, contended that the law was well settled, that the infringer was not restricted to such processes as were open at the date of invention, but was allowed to 'set up', as standards of comparison, all such processes as were open for use at the date of infringement. It was further contended, on the same side, that the logical extension of this rule permitted a 'day to day' standard; that is to say, for each day's infringement the defendant was entitled to fall back upon the

current art as it had been developed on that day. This interpretation seems to have had the endorsement of the Supreme Court in several previous cases, that is, it was upheld that the infringer is not restricted to the processes known at the date of the invention, but no authority existed for the 'day to day' rule until Judge Bourquin of the Montana court, in this flotation case, adopted it. In his recent opinion, Judge Bourquin instructed the Master to keep in mind the rule that the standard to be adopted by him in his accounting shall be "any standard that may be duly made to appear in respect to subsequent infringement". This permits the defendant to set up the current art from day to day throughout the period of infringement. The defendant may, for example, set up the 'A' process as that which was open and available to him at the beginning of his infringement, say, in 1911. He may apply this standard until the 'B' process is developed, say, in 1913, which 'B' process he may apply as his standard of comparison until, say, 1915, when he may set up the 'C' standard, which meanwhile has been developed in the art; or he may adopt any one or any combination of these processes for his comparison subsequent to the date at which the process was developed. There is no room for doubt as to the correct interpretation of this opinion. The effect of the decision may prove far-reaching. In the present case it will enable the defendant to fall back upon gravity concentration, '1% +' oil-flotation, and the electrolytic deposition of zinc. The result may be to show such small "gains, profits, and advantages" due from the defendant to the plaintiffs as to make it advisable for the plaintiffs to elect to take damages instead. If they should do so, they would have to show that there is an established royalty for the use of the patent covered by the patent in suit, or, in the absence of an established royalty, they would have to set up a 'reasonable' royalty. This will provoke a smile among many of our readers, for the license agreements of Minerals Separation cover the use of more than 60 patents; the royalties vary greatly, because many of them are based on the principle of 'all that the traffic will bear'. By the same token, it will be difficult to establish the reasonableness of these royalties. If the plaintiffs should be driven to make a claim for damages, we shall be curious to see how they will apportion the license fee as between the several patents set forth in the license agreements. For example, the patent in suit (No. 835,120) expires in 1923, but there is a suit pending against Butte & Superior in which that company is charged with infringing a patent, No. 962,678, on a so-called soluble frothing agent by the very acts that in the first suit are charged to have infringed No. 835,120, the froth-agitation patent. Judge Bourquin's decision may affect other cases also, namely, those pending against the Miami, Nevada Consolidated, and Magma companies. It looks as if Minerals Separation will be able to collect no more than royalties as damages, and in proving the reasonableness of such royalties and the apportionment of them between the several patents they are beset with several pitfalls.

Charcoal and Cyanidation

The granting of a United States patent to Messrs. K. Byron Moore and H. R. Edmonds for a special use of charcoal in the precipitation of gold from auro-cyanide solution draws attention to one of the most interesting developments in the history of the process. So far as can be ascertained, lump charcoal was first used in this connection in Victoria, Australia, and soon after the introduction of the MacArthur-Forrest invention; it was crushed in rolls, then screened and washed to remove the fine dust. Small precipitation vats were used, each of which was provided with an earthenware pipe, placed to stand in the centre of the vat, and filled with charcoal. The tubs were arranged in rows, and at different levels, so that gravity flow of solution from tub to tub was practicable. The liquor passed down through the central pipe in each tub, and upward through the mass of the charcoal, thence to the tub below. At intervals of twenty-four hours the top tubs were removed, the other receptacles being moved up into place, and tubs with fresh charcoal placed at the foot of the series. The spent charcoal was burned in a furnace, and the ash was smelted to recover the gold. The process was never adopted on an extensive scale; a large volume of charcoal was needed for a small plant, one treating 84 tons of solution per day was reported to require 198 tubs, each about two feet in diameter by about two feet high. Labor requirements were excessive; precipitation was inefficient, particularly unless fresh charcoal was substituted for the spent material at frequent intervals. The ash was easy to smelt, but it was bulky; the final recovery of the gold, therefore, was a costly operation. The more expensive zinc-shaving was considered cheaper in the long run, and was adopted universally as a precipitant. In a few instances charcoal has been utilized to save small amounts of gold that would otherwise have been lost and that may be found in the decanted solution from slime-tailing dams or in mines where the seepage from tailing-filled stopes contains a minute proportion of dissolved metal. The total amount of gold thus recovered, however, was and is negligible. Influential interests encouraged the use of zinc; there was no influential interest to favor the use of charcoal. No attempt was made to improve the technical methods of the 'precipitation' of gold by charcoal during two decades; when an improvement was made, it was the consequence of war-time economy.

For a long time the reason for the abstraction of gold from a cyanide solution by charcoal was a mystery, and a mystery in which few were interested. This was largely due to the fact that the result was always considered as one of precipitation by chemical action; no alternative explanation or suggestion was entertained. In 1913 an elaborate series of experiments was undertaken by a student in South Africa, who decided that the phenomenon—for it was a phenomenon at that time—was due to the action of the carbon monoxide gas that was occluded in the pores of the charcoal, a substance that, *per se*, could not, according to the laws of electro-chemical ac-

tion, precipitate gold or silver. Carbon monoxide gas also has no action on an ordinary auro-cyanide solution; but this objection was met cleverly by the assumption that the gas occurred in a condensed and active state in the pores of the charcoal, and was therefore different from the carbon monoxide of ordinary pressures. The negative result obtained by a comparison of the precipitating powers of charcoal before and after the abstraction of the carbon monoxide at low vacuum and normal temperature was explained by the contention that the loosely-held gas was valueless as a precipitant. The carbon monoxide theory received universal support. Additional and confirmatory hypotheses were advanced from time to time, some of which suggested that the result of the chemical action that was alleged to occur was a carbonyl auro-cyanide, of varying analysis.

In 1915 it was suggested in the transactions of the Institution of Mining & Metallurgy, after an independent research on the subject of the physical influences of surface concentration and absorption, that the adsorptive effect of colloidal carbon when in contact with gold-bearing cyanide solution might well form the basis of research. This suggestion arose from a disinclination to credit chemical action with any share in the result of the so-called precipitation of gold by charcoal. In 1916 or 1917 the first intelligent step seems to have been taken on a practical scale to use charcoal efficiently, and by the engineers whose names appear in the first paragraph of this résumé. Laboratory experiments indicated that fine charcoal was a much more effective 'precipitant' than the lump charcoal previously used. The inventors, in spite of the scientific significance of such a fact, still clung to the carbon monoxide theory, even when it was found that water-quenched and wet-crushed charcoal was twenty times more efficient than air-dried dry-crushed charcoal. In another quarter it was suggested that the quenching and crushing in water removed the occluded gases, to a great extent if not entirely; 'precipitation' was more efficient under such circumstances, so that it seemed reasonable to assume that carbon monoxide had nothing to do with the reaction; it was suggested that the abstraction of gold was entirely due to the adsorption of the auro-cyanide compound in the solution, and this theory received additional support from the fact that the efficiency of 'precipitation' was found to be directly proportional to the amount of surface exposed by the charcoal. By using solutions of graduated gold content, the abstraction of the metal was found to obey the laws of adsorption. Fine grinding was an essential to success. The action was physical and not chemical; the problem could have been solved in a few weeks by a physical chemist; but, strange to relate, the average cyanide metallurgist thinks little of physics in connection with the changes that occur in treating ores and recovering metals. His confrere, the flotation specialist, appreciates the distinction between physical and chemical action, and realizes the importance of surface-tension and surficial concentration; but the cyanide metallurgist usually prefers to argue almost entirely from the chemical point of view.

Physical effects such as adsorption and capillarity are unanny and, to a certain extent, inexplicable; consequently, no advantage has been taken of the work of contemporary scientists in an attempt to explain the adsorptive nature of charcoal as a 'precipitant' of precious metals. Researches on the relative effects of various types of wood-charcoal on a solution of mercuric cyanide were made in Europe recently; the physical chemist in charge of this work would have smiled a smile of incredulity if it were suggested that the mercury was being precipitated by carbon monoxide or other gas. And yet, had physics instead of chemistry been applied to the problem that confronted the cyanide engineers in the early days of the industry, and if charcoal in various physical forms, fine and coarse, had been tried, many economies might have ensued.

The new Moore-Edmands process has been tested on a commercial scale in Western Australia and, it is understood, in Africa. The scope of the new 'precipitant' and the practicability of its comprehensive application have yet to be determined. Nevertheless, convincing empirical results have been obtained, all the more interesting because the patentees apparently failed to appreciate the scientific or theoretical significance of their discovery. An exceedingly clean and finely ground adsorbent is essential to maximum 'precipitation'; this is obtained by allowing the red-hot charcoal to drop through the grate-bars of a producer-gas plant and into water; it is then pulverized in a ball-mill. The emulsion is mixed with the auro-cyanide solution, and cakes of the charcoal are formed in a miniature Butters filter; after a definite period these are discharged, re-pulped, and re-formed on the leaves by the application of vacuum. The extractors are operated in series; the one in which the cakes are approaching saturation receive the richest liquor, the tailing solution going to the second extractor being finally impoverished by contact with fresh charcoal. The final cake, loaded with gold, is filter-pressed, dried, and smelted in the ordinary way. A tilting furnace, which provides large capacity, has been found to be suitable for the purpose.

The gold industry needs encouragement. Any suggestions toward cheapening the cost of cyanidation should be welcomed. The new process offers possibilities in this direction by the utilization of charcoal, which is obtainable almost anywhere and at a negligible cost. A realization of the theory of the underlying reaction of such 'precipitation' will help to minimize losses in those cases where charcoal is found in the ore and stope-filling going to the mill; for it is evident that every precaution should be taken to avoid the reduction in size of such material when it is to be used as a precipitant, and when 'precipitation' means loss. The use of zinc in the operation of the cyanide process has always been accompanied by disadvantages, for soluble double cyanides are formed. These are of little or no value as solvents of the precious metals; they are amenable to the detriment of efficient extraction of the gold in the dissolving stage and of efficient precipitation in the zinc-box or press. Various al-

ternatives have been suggested. Thus, in a recent article in the technical press, it was shown, in a slime plant where excessive dilution of the pulp was practised and where much solution had to be discarded, that the precipitation of the gold in the zinc-boxes was exceptionally good. In another part of the plant, where the zinc accumulated in the solution to an undesirable extent, a drip of strong cyanide was needed to raise the amount of free cyanide in the liquor entering the boxes; the necessity arose because of an accumulation of zinc in the solution; the cyanide was there as the double salt; it was not available for precipitating purposes. The remedy increased the trouble, and resulted in a further loss of both solvent and precipitant, for zinc is readily soluble in cyanide. Excess cyanide is not needed when charcoal is used; in fact, a prominent characteristic of adsorption is that "the amount of dissolved substance taken up by the solid increases much more slowly than the concentration of the solution; the removal of the substance is relatively more complete in dilute solutions". Thus with a solution containing 2.16 milligrammes of gold in 200 cubic centimetres of solution it was shown that 96% of the metal was adsorbed; with a solution of ten times that strength, and by using the same amount of charcoal, only about 50% was adsorbed. Similarly it was found that, after a ten-fold increase in concentration of an aqueous solution of acetic acid, the adsorptive capacity of charcoal was not even doubled. A few experiments would prove whether or not the silver present in a cyanide solution resulting from the treatment of an average gold-silver ore was in such quantity that efficient 'precipitation' with charcoal could only result after dilution or by repeated treatments; it is suggested that the good results obtained in the case of auro-cyanide solution may be due to the comparatively low concentration of the metal.

When aluminum was introduced as a substitute for zinc in normal cyaniding operations it was hoped that its use would become general, for no deleterious compounds are formed in the solution. But, unfortunately, other troubles arose, which indicated that the disadvantages more than countered the advantages. At the New York & Honduras company's mill in Honduras, for example, it has been found that the maximum capacity of the plant is reduced by 1000 tons per month when aluminum is used, because the addition of sufficient lime to ensure coagulation and settlement of the slime is impracticable, and, under such conditions, the thickeners function at a seriously reduced capacity. The incrustation of the equipment also causes much trouble and expense when aluminum is used as a precipitant. The improvements resulting from the adoption of the practice of de-aerating the solution before precipitation by zinc (the Crowe process) are such that considerable reductions in the consumption of precipitant and solvent have been reported. The adoption of charcoal, if its use could be demonstrated as practicable, would obviate all difficulties arising from fouling of solution or incrustation of equipment; for the action is a physical one, and no deleterious compounds are formed.

DISCUSSION

Revision of the Mining Law

The Editor:

Sir—The law as drafted appears to be the result of long and careful study on the part of its projectors; nevertheless it seems vulnerable to criticism on both its theoretical and practical sides, as I shall now endeavor to show.

In theory it has failed to lay a democratic foundation for the future expansion of the mining industry: first, by allowing freehold tenure; and second, by the union of subsoil and surface rights. These two errors are responsible for the widespread speculation and monopoly now existing in the mineral lands of the Eastern States, and—coupled with the lax enforcement of compulsory work for unpatented claims—account for the same conditions in the West. A similar result was produced by the Mexican mining code of 1892, which abolished the ancient requirement of continuous work and substituted for it a trifling annual tax on the area held. By 1905 this change of policy had already produced the following unhappy results, according to Licenciado Miguel Mejia*:

"The mine-owners found it convenient to pay the tiny areal tax and then to shut-down, sometimes for want of working funds but oftener owing to bad faith on the part of the directorate, which wished to depreciate the company's shares in order that they might acquire them cheaply from the small stockholders. Some were even cleverer, for they monopolized whole mining districts by new denouncements and kept them unproductive, so that none of the old mines could be worked or any explorations made for new ones. What resulted from this new order of things? The mines stopped their payrolls and the half-starved miners were driven into exile, thereby ruining the merchants and a multitude of other people who depended on the mines. Families began to emigrate, and houses became vacant; the local governments could not be sustained, and whole towns were ruined. Even the Federal government found that it lost more from this decrease in local taxation than it gained by the new mining tax. Such have been the disastrous effects of this law, which deprived the nation of its former free access to its mineral deposits and permitted them to be monopolized and held idle indefinitely."

In 1910, at the beginning of the Revolution, this condition became worse, for there existed hardly a mineral outcrop that had not been covered by a denouncement.

*"Documentos Relacionados con la Legislacion Petrolera Mexicana", published in 1919 by the Secretario de Industria, Comercio, y Trabajo, Mexico City.

But legislation since 1914 has corrected this evil by the simple device of so increasing the areal tax as to make land speculation unprofitable. For those exceptionally rich districts in which the areal tax alone would be insufficient to prevent forestalling, the Mexican law permits obligatory work to be prescribed. In consequence of these changes the bulk of the former monopolized areas are now open for denouncement, and it may be said truly that Mexico now offers a better field for the prospector and small operator than any other country in the world.

From the experience of Mexico it is thus safe to conclude that any measure that encourages the idle holding of mineral land is a bad thing for the community, whether the result of too low an areal tax, as prevailed there between 1892 and 1914, or because of the turning of a leasehold into a freehold title, as is done by the United States provision concerning the patenting of claims. A patented claim could be taxed as much as an unpatented one, but the patenting removes the ground from the jurisdiction of the Federal into that of the local government, which, in few cases, has any provisions in its tax code that have been designed to prevent speculation in mineral land. Therefore, I can see no object in requiring that all claims be patented within seven years, as is proposed in the new law; indeed, it would seem wiser at least to continue leasehold titles in every State that had failed to bring its tax or work requirements for mineral land up to the minimum prescribed by the Federal code†. This would be following the mining experience of Australia, where freehold titles have generally been replaced by leaseholds.

Even more important than the retention of the leasehold title is the question of the separation of subsoil from surface rights. This the new law should have introduced when it dropped the existing provision for apex rights. The first important modern code to embody the principle of subsoil rights as a separate property from the surface was that of Carlos III, which was applied in 1783 throughout the Spanish dominions. It assumed the subsoil to be royal or public property, and gave any citizen the right to denounce it anywhere for mining purposes, irrespective of the ownership of the surface. This code prevails today, with few modifications, in all the Spanish-American republics; that its principles were never introduced into Portuguese America is perhaps the chief reason for the present backward mineral development of Brazil.

†"Principles of Mining Taxation." Discussion by me. Trans. A. I. M. E., 1919, p. 709.

In the scrutiny of ancient institutions by the statesmen of the French revolution, property in mines was not overlooked. This is indicated by the following speech of Mirabeau. "If it be asked whether mines are essentially private properties dependent on the surface ownership, I reply that society has created property in land solely on condition that it be cultivated, and from this aspect only its surface is involved. Society has never been able to class as property those objects whose conservation it could not guarantee. How could it prevent a mine from being exploited at 1200 ft. beneath a land-owner who claimed to own it? Common good and justice are the two foundations of property, but neither requires that mines be accessories of the surface. I say that the interior of the earth is not susceptible of division, whereas on the surface it is to the social interest that property be divided." These ideas of Mirabeau, as to the advantage of separating subsoil from surface rights, were later accepted by the legal committee of the French Convention, and were finally, a few years afterward, embodied in the famous Napoleonic code, which now prevails in modern France and Italy.

If we look at the condition of mining property in our Eastern States, either from the standpoint of elementary justice or common sense, we may observe the ridiculous results of the rejection of the ideas of Mirabeau. Some Pennsylvanian farmers draw unearned fortunes in royalties from the coal seams beneath their land; their neighbors, just as worthy in every respect, lack the coal and must therefore plough for a living. One Indian tribe in Oklahoma lives like a family of nabobs, because its lands contain an oil-pool; another tribe has to ride the range if it wishes to eat. Nor is this absurd condition confined to non-metallic mineral lands. In Missouri we find the land-owners of Elvins selling their scrub-oak pastures for \$3000 an acre because of the underlying lead ore; in Wisconsin we see the erstwhile German peasants of Platteville living like Junkers on their zinc-ore royalties; in Minnesota we note the roughneck lumbermen of the Mesabi range blossoming out into the millionaire iron-ore fee-owners of Duluth.

"All this may be true", some may say, "and if we had to begin over again we might heed its import; but a multitude of vested rights have arisen under our existing system, and, unfair though they be, it is now too late to make any change." Such arguments are the stock in trade of conservatives in all ages and countries, but they are invalid from the standpoint of human progress. The violent revolutions of history—in Russia, for example—have been caused by the attempts of governments to enforce vested rights that have long been condemned by public opinion as oppressive and unjust. Would it not be a good augury for the stability of civilization if all nations should incorporate in their codes the following principles from the famous Article 27 of the Mexican Constitution? "The Nation will always have the right to impose on private property such taxation as the public interest may require, and to control the natural resources, susceptible of appropriation, for the purpose of conserv-

ing them and assuring an equitable distribution of the public wealth. . . . The ownership of the Nation in all mineral deposits and national waters is inalienable and imprescriptible, and working concessions can only be granted to individuals on condition of their regular development as required by law."

Owing to the fact that the United States only controls as owner the landed property of the greatly depleted public domain, and, as sovereign or owner, that of the Alaskan territory and the colonies, any reforms now introduced could only become widely effective by being imitated by the individual States. Nevertheless, I believe a favorable opportunity is now offered to inaugurate a new Federal mining code, as a model for State legislation in that epoch, not far ahead, when all the public domain of any economic value shall have become private property.

The separation of surface from subsoil rights could be arranged easily, both for future leaseholds on the public domain, and for freeholds as well as leaseholds in the national territories or colonies. In the former case a prospector would henceforth be allowed to locate only the subsoil rights as a mineral claim; any surface he might require he could purchase either from the Federal government or from its private owner, as the case might be, to facilitate which, mining should be declared a public use as under the Napoleonic code and in Australia†: a cheap, quick, and simple procedure should be provided for the legal application of eminent domain. The separation, in the case of existing leaseholds or freeholds under Federal jurisdiction, would imply a new statute for the division of surface from subsoil property in the official tax-lists, so that each could be taxed independently. There would be no need for separating land-rights in existing deeds or records; such separation would only be required for all sales post-dating the new statute.

The adoption of this separation system on the public domain would save further expense for the payment of geologists needed to classify it into 'mineral' and 'non-mineral' land—a classification that is sure to be faulty at best. By the taxing of subsoil rights separately, at a sufficiently high rate to discourage speculation, the bulk of such rights where economic minerals were yet undiscovered could be recovered gratis by the Government at tax sales. Thus vast subsoil areas now controlled by stockmen or farmers would again be open to prospectors, who would thus regain the rights that were usurped when a multitude of surface-owners claimed the subsoil in spite of its exemption in their original titles from the Nation. By the sincere enforcement of such provisions, we would soon reach the ideal condition for the working, as distinguished from the parasitic, miner—when all subsoil rights would be freely open to exploration and development, without consulting the surface-owners, except in cases where the ground had already been opened for minerals.

I agree with most of the contributors to the discussion in deeming objectionable many of the regulations of the

†'Mining Laws of Australasia', by A. C. Veatch, Bull. U. S. Geological Survey, No. 505.

new law. The attempt to locate most metal-mining claims in the same way as agricultural land, by means of section lines, could only be advocated by persons who have had little experience as mineral surveyors. Mineral deposits were created 'every which way' as to direction, and should be located solely with reference to the latter, so as to occupy the least possible area. Then some fixed point on the claim should be connected on the map with a central monument, natural or artificial, for the whole district. This is now the rule in Mexico, where in most districts there is a village church to select as the monument of reference. Thus, all the claims in a district can be plotted on a single map, and any invasions or overlaps can be detected easily, irrespective of public-land surveys, whose presence or absence is of no concern to us here.

Next, I consider a 10-acre unit of location far too large; the Mexican unit—the hectare—is just right, and could be adopted easily in English measure by taking a square of 33 ft., which covers 2.5 acres. Some day, I hope, the foot will be everywhere abandoned entirely in favor of the metre, and the suggested unit will then be in harmony. With the hectare-unit a claim can be constructed to fit any vein-system closely, by using the hectares as blocks that are built up into a rectangular polygon.

It is clear that the present system of registering claims in the County Recorder's office is convenient, but the Recorder should be required to report each new claim to the nearest U. S. Land Office. A claim should be monumented, within a few months of location, with masonry posts at its corners and sides, so that anyone, without being a surveyor, can follow it. Lastly, there should be provision for nullifying a claim, forfeited for default of development or tax requirements, at the request of anyone interested; so that after a short time for publication it would be again open for location.

Flotation of Precious Metals

The Editor:

Sir—Both native gold and native silver may be floated after the ores have been ground in a ball-mill. I venture to state that this is not common knowledge, although it has been mentioned by several metallurgists. There are many mines that cannot be worked profitably because such metals will not amalgamate, and the presence of oxidized copper minerals prohibits the use of the cyanide process. For such ores the flotation process may prove successful. I say "may" because the process must be tried first; for although gold may float from one it may not float from another.

These notes refer to two commercial mills operating at a profit, and not to laboratory experiments; the mill treating the native silver ore will be referred to as the silver-mill, and that treating the gold ore as the gold-mill. In both the classifier overflow fed the flotation

machines; K & K flotation machines were used. The K & K has the advantage over other machines in that one portion may be used as a rougher while another section is cleaning. In treating a gold or silver ore this is important, for the bulk of concentrate produced is comparatively small, and it is a distinct advantage to be able to change the cleaning space at will.

In the silver-mill, coarse native silver lodged in the eddies at the discharge of the ball-mill, and fine flake silver could be seen in the concentrate. In the gold-mill, coarse gold could be panned from the ball mill discharge, fine gold could be panned from the concentrate, but no gold could be panned from the tailing. In both mills, a mixture of crude-oil and No. 5 General Naval Stores pine-oil was used for floating the metals; neither soda ash nor sodium sulphide proved advantageous.

Amalgamation may be conducted in a ball mill or classifier circuit when crude-oil or Diesel oil is used in the ball-mill; in the gold-mill the crude-oil proved to be beneficial. When amalgamating without crude-oil, the

FINE GRINDING AND TAILING CONTENT

plates fouled rapidly; with the crude-oil ground into the ore the plates remained bright and active, the sulphides and semi-oxidized products being carried over with the oil without touching the plates. The results in the gold-mill were good, whether or not the plates preceded the flotation machine, but nevertheless it was considered best to amalgamate as much gold as possible.

It is difficult to define the necessary conditions for the successful flotation of native metals, but I can say that fine grinding is required; all the pulp should pass 80-mesh. The graph shown herewith illustrates the rise and fall in the assay-value of the tailing as the screen-analyses showed finer or coarser grinding. Finer grinding meant less capacity, but when reduced to profit and loss it showed a gain.

From my experience I can say that a dilute pulp, for example, 1 of ore to 7½ of water, is not disadvantageous; a thin and light froth is better than a heavy, thick, and persistent one. The classifier discharge, when using a ball-mill on crusher product, may be kept at a moderate moisture content without the use of a thickener; but, if

stamps precede the ball-mill and no thickener is used, the classifier discharge may contain as much as 8 parts of water to 1 of ore.

When floating a native-metal ore containing only a small amount of sulphide minerals the concentrate contains a large proportion of gangue, for it is not probable that ore could be concentrated to a ratio over 200 to 1 without making an unmarketable middling or a high-grade tailing. For a $\frac{1}{2}$ -oz. gold ore this would mean a \$2000 concentrate. I venture to state that a 100 to 1 ratio is more likely; as, even in an 80-mesh product, much of the gold is not entirely free from gangue; and, in order to float the very fine gold, most of the slimed oxides must be carried in the froth.

I do not think that a small testing-machine will give satisfactory results on free-metal ores in those instances where the amount of metal is small as compared with the bulk of the ore; for conditions are more easily regulated when treating a greater bulk. A small test-mill of 10 to 20 tons per day will give results that may be duplicated on a much larger scale. An example will suffice: With a small machine a test showed an extraction of 41%; this was verified at the start in a 20-ton mill; but, by gradually altering conditions and noting results, the extraction was doubled in a short time. Another case I may cite to show how time and conditions may affect results: In a silver-lead-zinc mill for many months the tailing assayed from 3 to 5 lb. zinc per ton; by continually increasing the amount of froth in the roughing machine this loss was reduced to 0.5 to 0.8 lb. per ton. These variations in operating results can only be obtained when treating a sufficient bulk of material and where a small variation will produce a very small change.

The silver ore treated in the silver-mill at times contained a considerable polybasite, but the results were the same as when native silver predominated. The following figures show the every-day results at the silver-mill; samples were taken on each of the three shifts and then averaged for the day; the average given covers two months operation: heads, 11.27 oz. silver; tailing, 1.5 oz.; and concentrate, 1189 oz. This gives a ratio of concentration of 121 to 1 and an extraction of 86%. The actual recovery was not determined; the concentrate was not gathered daily but allowed to settle and then dried.

The results at the gold-mill, when treating an oxidized gold ore containing lead carbonate and in which but 8% of the gold could be amalgamated on plates, averaged in gold content: heading, 0.87 oz.; tailing, 0.14 oz.; concentrate, 22.2 oz.; ratio of concentration, 25 to 1. The extraction was 84%, which tallied closely with the actual recovery.

My aim in writing this is to show that a silver or gold ore in which the metals are in a native state and cannot economically be recovered by amalgamation or cyanidation may be treated profitably by flotation. I hope others who have had experience along these lines will give their ideas.

Surface-Tension in Flotation

The Editor:

Sir—Your issue of August 13 contained an article by A. Fahrenwald giving methods and data on measurements of surface-tension. Your contributor quotes the Willard Gibbs formula. $U = \frac{c}{RT} \frac{ds}{dc}$, "where U is the excess concentration at the boundary surface in grammes per centimetre, c is the concentration of solute in the bulk of the solution, R is the constant of the simple gas equation, T is the absolute thermodynamic temperature, and s is the interfacial tension". It is pertinent to point out that, as yet, this formula has not been proved to be true for colloidal solutions and can be applied properly only to cases of true solutions.

Further, Fahrenwald's measurements were made by a static method: measurements by a dynamic method would probably give data of greater interest. Lord Rayleigh devised a dynamic method by which surface-tensions of liquids were measured before the surfaces were one-thousandth of a second old.

That such measurements of surface-tension would be of interest, with reference to the relative persistence or lack of persistence of a froth, is indicated by the following figures, taken from Freundlich's 'Kapillarchemie', p. 56.

		Dynes per centimetre	
		static	dynamic
Water	75	75
Sodium oleate	0.025 %	55	79
"	" 0.25 %	26	79
"	" 1.25 %	26	62
"	" 2.5 %	26	58
Heptylic acid	0.005N	54	68

In the usual agitating-frothing machines, fresh liquid surfaces are made rapidly, and the values of surface-tension obtaining are obviously between the static and dynamic values.

Seattle, September 8.

Silver in the Philippines

The Editor:

Sir—I call your attention to a misstatement in the issue of July 9, taken from a consular report, in regard to silver deposits in Bulacan, Paracale, Cebu, Marinduque, and Mindanao, in the Philippine Islands. I have seen the same mistake in a bulletin of the American Mining Congress.

The Division of Mines of the Bureau of Science has no knowledge of silver deposits in the Philippines. Such silver as occurs in the ores is usually alloyed with gold. We have no knowledge of commercial deposits of silver. Native silver has been found in minute quantities in one or two places and there is some argentiferous galena in two or three localities. All of these deposits, however, are unimportant.

WARREN D. SMITH,

Manila, P. I., August 26.

Chief, Division of Mines.

Huxley: The Exponent of Veracity

By T. A. Rickard

*Huxley was one of the group of scientific men associated with the birth of the central doctrine of evolution; he was a personal friend of Darwin and his militant ally during the bitter controversies arising from the publication of the 'Origin of Species'. That was in 1859—62 years ago—yet the modern world still feels the intellectual impulse of that first declaration of the Darwinian hypothesis, to establish which Huxley devoted the best of his powers as an expositor and dialectician.

It may be worth while to recall the romantic story of the announcement of Darwin's discovery of the principle of natural selection. He had been prepared to think on the subject, and to collect notes for his study of it, by his voyage as official naturalist on board the 'Beagle', a vessel used by the British government in the survey of the southern end of South America during five years, from 1831 to 1836, but he did not see the light until 1837, after his return home, when he had begun to compare the relations of existing with extinct species and the species of different geographic areas with one another. In 1842 he wrote a brief sketch of his theory in pencil and two years later he elaborated this into an essay of 230 pages. He was sufficiently convinced of the importance of his work to make arrangements for its publication in case of his death. Only two or three friends were cognizant of his views; among those friends were Lyell, Hooker, and Huxley. Early in 1856 he began to write on an extended scale, and in July of that year he outlined his theory in a letter to Asa Gray, of Harvard; he was engaged in preparing his book when in June 1858 he received a letter from Alfred Wallace, a naturalist, who was then in the Malay Peninsula, and with whom he had been corresponding. With this letter from Wallace he received an essay in which Wallace propounded almost exactly the same views as his own. As Darwin said at the time: "If Wallace had my manuscript sketch written out in 1842, he could not have made a better short abstract". It was an astonishing coincidence, and, of course, a great blow to Darwin. What did he do? He was a gentleman in the best sense of that much abused word. His first impulse was to publish Wallace's essay without comment of his own, but Lyell and Hooker suggested that extracts from his manuscript of 1844 and from the letter to Asa Gray should be communicated to the Linnean Society along with Wallace's essay. This was done on July 1, 1858. Hooker, describing the meeting, said that "the interest excited was intense, but the subject was too novel and too ominous for the old school to enter the lists before armoring. After the meeting it was talked over with bated breath". Darwin and Wallace remained friends to the

end of their lives. Wallace acknowledged generously that while he had been the originator of the theory, he could not have written the 'Origin of Species', nor persevered, as Darwin did, in accumulating and using large masses of facts of the most varied kind in the preparation of vast generalizations. The true spirit of science and the instincts of fine character were never better exemplified than in the sayings and doings of the great men who introduced the theory of evolution into the world. Huxley was the most brilliant and in many respects the most remarkable member of that group.

Thomas Henry Huxley: the name fits the man. He was unaffected, passionately sincere, gloriously belligerent, ever a fighter who marched breast forward. His first name, as he said himself, was that of the "particular apostle with whom he had always felt most sympathy": Thomas, the doubter. See John XX, 25. The philosophy of doubt in his hands became the key to scientific truth. Descartes and Hume were his exemplars. Often he quoted the resolution made by Descartes: "To take nothing for truth without clear knowledge that it is such", the practical effect of which is the sanctification of doubt. He took no direct pleasure in doubting, however, but used it as a means of making knowledge doubly secure. As he said:

"The development of exact natural knowledge in all its vast range, from physics to history and criticism, is the consequence of the working out, in this province, of the resolution to take nothing for truth without clear knowledge that it is such; to consider all beliefs open to criticism; to regard the value of authority as neither greater nor less than as much as it can prove itself to be worth. The modern spirit is not the spirit 'which always denies', delighting only in destruction; still less is it that which builds castles in the air rather than not construct; it is the spirit which works and will work 'without haste and without rest', gathering harvest after harvest of truth into its barns and devouring error with unquenchable fire."

Huxley was born in 1825, in the village of Ealing, now a suburb of London. Like Herbert Spencer, he was the son of a schoolmaster. From his father he inherited a hot, but generous, temper, an inborn faculty for drawing, and a tenacity of purpose, "which", as he said, "unfriendly observers sometimes called obstinacy". To his mother he owed much more, especially rapidity of thought. Of her he says: "If one ventured to suggest she had not taken much time to arrive at any conclusion, she would say, 'I cannot help it, things flash across me'. That peculiarity has been passed on to me in full strength; it has often stood me in good stead: it has some-

*An address delivered at the Commencement of the Montana School of Mines, at Butte, on June 3, 1921.

times played me sad tricks, and it has always been a danger. But, after all, if my time were to come over again, there is nothing I would less willingly part with than my inheritance of mother wit". He was one of the wittiest men of his time. During a dinner at the Athenaeum club, Spenceer remarked: "You would not think it, but I once wrote a tragedy". Huxley exclaimed, "I know the catastrophe". Spenceer asked what it was. Huxley replied, "A beautiful theory killed by a nasty ugly little fact". That is Galton's version. Others have been quoted; for instance: "Spenceer's idea of a tragedy is a deduction killed by a fact". Upon another occasion some of his friends were discussing habits of composition, most of them acknowledging their difficulty in getting into the swing of it. Whereupon Lewes exclaimed, "I never hesitate. I get up steam at once. In short, I boil at a low temperature". "Well, but", remarked Huxley, "that implies a vacuum in the upper regions." When Archbishop Benson helped him to put on his overcoat, he said: "Thank you, I feel as if I were receiving the *pallium*". Once during a lecture, turning to a student, he asked: "Well, I hope you understand it all". "All, sir, but one part, during which you stood between me and the blackboard", was the reply. Huxley rejoined: "I did my best to make myself clear, but could not render myself transparent".

His regular schooling was scant and poor, but he was an eager reader of books and made the most of his father's library. Picture him as a boy of twelve, lighting a candle before dawn, pinning a blanket about his shoulders, and sitting up in bed in order to read Hutton's 'Geology'. He had an intense curiosity to discover the motive principle of things and early showed a love for metaphysics, engineering, and anatomy. The fact that he had a medical brother-in-law appears to have been the chief reason why he commenced the study of medicine while still a small boy. When not yet 14 years old he attended his first post-mortem examination, and somehow was poisoned. Although he soon recovered from the immediate effects, he suffered from hypochondriacal dyspepsia the rest of his life. Like his friends, Darwin and Spenceer, he accomplished a great work despite persistently poor health. Thus will the spirit of man—of great men—triumph over obstacles that suffice to drive weaker men to despair. He persevered in his studies. The reading of Carlyle prompted him to begin the learning of German at 15. He also learned French. In after years he mastered Italian in order to read Dante and late in life he took up Greek, for scientific use and to read Homer in the original. His ability to read foreign literature proved immensely valuable to him, giving him an early acquaintance with German method and French philosophy, besides widening his intellectual sympathy with other races. To good music he was always susceptible. When 17 years old he obtained a scholarship at Charing Cross hospital, where he came under the stimulating influence of an excellent teacher, Wharton Jones, the lecturer in physiology. He won prizes and medals, and otherwise demonstrated the budding powers of his

mind. When just 21, and still too young to qualify at the College of Surgeons, he applied for a post in the Medical Service of the Navy, and in October 1846 he was appointed assistant-surgeon on the 'Rattlesnake'. That was the turning point of his career.

It is noteworthy that Huxley, Darwin, and Hooker alike were enabled to study natural history by means of a marine curriculum. Darwin sailed on the 'Beagle' in 1831, Hooker on the 'Erebus' in 1839, Huxley on the 'Rattlesnake' in 1846. In later years, armed with the knowledge acquired during their voyages, they stood together in the fight against the theory of an immutability of species. Each of the ships to which they were commissioned was sent forth on a scientific mission; to the 'Rattlesnake' was assigned the survey of the passage between the Barrier Reef and the north-eastern coast of Australia, and the exploration of the sea from there northward to New Guinea. It proved a fine apprenticeship for the study of biological problems and helped Huxley to become the foremost expositor of the doctrine of evolution.

He remained on the 'Rattlesnake' four years. During this period he used the microscope assiduously in examining the specimens of marine life collected by the dredge and the tow-net, supplementing his observations with conscientious drawings of innumerable dissections. While Huxley was engaged in this work on board ship amid the coral reefs of the southern seas, forming a new conception of the animal kingdom as a varied set of modifications of a single type, Darwin at his quiet home in rural England was slowly working toward a philosophic explanation of the variation of species by modification and was preparing to formulate the fundamental concept of modern science.

While attached to the 'Rattlesnake', Huxley wrote numerous papers; for one of these, on the structure of the Medusae, he was given the blue ribbon of British science, fellowship of the Royal Society. On his return, after the long voyage in distant parts, he wrote a number of other papers, which won recognition and many medals; but they did not provide bread and butter. He was poor. At this juncture, in 1854, when he was 27, he and Tyndall applied for appointment to the chairs of natural history and physics respectively in the University of Toronto. Both were rejected. One cannot forbear from speculating upon the consequences to North American science and culture if these two men had taken root on this side of the Atlantic. Possibly their usefulness on a larger scale would have been impaired; probably they would have done less well in the absence of the stimulus given to both by being in the midst of great controversies in Europe. Instead of going to Canada, Huxley obtained the professorship of paleontology and the lectureship on natural history in the Royal School of Mines, which in later years has been annexed to the Imperial College of Science and Technology at South Kensington. From these two appointments he drew the lordly salary of £200 per annum! yet he held them for 31 years, until "that accursed bag, dyspepsia" and

other ailments compelled him to retire in 1885. Four years after his appointment at the School of Mines, he was joined by Tyndall, as professor of physics. Hitherto Huxley's work had been concerned with invertebrates, now he had to cover a much wider field. Soon he acquired an ample knowledge of paleontology, thereby arming himself further for elucidating the problems that became so hotly contested as soon as Darwin's 'Origin of Species' was published in 1859. He used the Museum of Practical Geology as an educational instrument. Indeed, characteristically, he became keenly interested in the organization and use of museums; he re-arranged the courses of study at the School of Mines; and began a set of lectures to working-men. These are famous now; they were as fit for Prime Ministers as for working-men and enabled him to acquire the tremendously difficult art of talking about scientific subjects in plain English, an art he mastered so thoroughly that he became the greatest scientific expositor of his time. In the following year, 1855, he became naturalist to the Geological Survey, with an additional salary of £200, afterward increased to £400. Various lectureships were offered to him in quick succession. At last he had an income that allowed him to marry Henrietta Heathorn, whom he had met and to whom he had become engaged while on a visit to Sydney, in Australia, eight years previously. His dislike of pre-variation is shown by an incident at this time. Miss Heathorn was in bad health; he took her to a famous doctor as if she were merely a patient in whom he was interested. Then, as one doctor to another, he asked the specialist for his private opinion of the case. "I give her six months to live," said he. "Well, six months or not", replied Huxley, "she is going to be my wife." The doctor was annoyed. "You might have told me that before." It was the evasive answer in such a contingency that Huxley wished to avoid. Fortunately another specialist gave a more hopeful opinion, which proved correct. Mrs. Huxley outlived her husband, who himself lived to be 70 years old; she was the mother of boys and girls that have become men and women of note.

Once started, he advanced steadily, making enough money, as lecturer and writer, to pursue his own researches and live in the style of a successful professional man. He became a persistent advocate for scientific education in schools and colleges; he aroused public interest in biology and in other sciences, such as geology; he awakened the curiosity of large audiences in natural history; he co-operated with Roscoe and Balfour Stewart in an organized endeavor to diffuse scientific knowledge among all classes. And he succeeded. In his prime he was recognized as the greatest expositor and dialectician of the period. He was illuminating and penetrating even to minds poorly prepared for his teaching. Take, for example, his lecture 'On a Piece of Chalk', as delivered to the working-men of Norwich in 1868. He begins by holding a piece of white stuff before the eyes of his audience, he tells them it is carbonate of lime, he explains how it is built of dead organisms buried on the bottom of the sea, he shows how out of their substance the cliffs of

Albion have been formed, he reads the story of evolution as written on the face of the rocks he recounts "the fairy tales of science and the long march of time", and so passes the current of his genius through the piece of chalk that it becomes incandescent to the dulled intelligence.

He was the recognized exponent of Darwinism. Of him it could be said, as of Luther in relation to Erasmus, that he hatched the egg that Darwin laid. Without his powerful advocacy the doctrine of evolution would have made slow progress in the minds of the world at large. He was a pioneer of human thought, an explorer who cut his way through the stifling jungle of myth and the muddy morasses of ignorance to the cool high summits of scientific truth.

Among the events in Huxley's life that typify his

THOMAS HENRY HUXLEY

character and achievement, I shall try to describe two. The first was the dialectic combat with Owen and Wilberforce in 1860. In that year the British Association for the Advancement of Science met at Oxford. The air was full of the controversy over Darwin's book, 'Origin of Species', which had been issued in the preceding November. On December 26 the 'Times' published a review, which, although unsigned, was written by Huxley, to whom fortunately the official reviewer of the 'Times' had turned for help, being himself unversed in scientific matters. Thus Huxley was given an early opportunity to write a splendid essay in support of evolution. Darwin, at first, was not aware of the identity of the reviewer, but, as soon as he saw the article, he said, "Whoever the man is, he has done great service to the cause". Most of the press notices of the book were unfavorable.

In the following April Huxley contributed a long article to the 'Westminster Review', praising Darwin's work and insisting upon natural selection as the only satisfactory hypothesis then in the field. In the same month the 'Edinburgh Review' published a vicious assault not only upon the 'Origin of Species' but also upon Darwin and Huxley. This was marred by personal abuse and displayed a venom that shocked them and their friends. The article was not signed, but its range of knowledge and the style of its argument betrayed its authorship. Only Sir Richard Owen could have written it. He was then the most distinguished anatomist in England, prominent in fashionable society, a leader among scientific men, brilliant, perverse, and unscrupulous. He was jealous of the new group of men—Darwin, Huxley, Hooker, and Lyell—who were threatening his premier position in English science, and he had been urged by Wilberforce, the Bishop of Oxford, together with Sedgwick, Whewell, and other church people, to stamp out "the pernicious doctrine" of evolution. Another article appeared in the July issue of the 'Quarterly Review'; this was recognized as the work of Wilberforce himself, who, assisted by Owen, made a bitter drive on Darwin. Seventeen years afterward, in 'Darwin's Life and Letters', Huxley wrote of this article as follows:

"I doubt if there was any man living who had a better right [than Darwin] to expect that anything he might choose to say on such a question as the origin of species would be listened to with profound attention, and discussed with respect. And there was certainly no man whose personal character should have afforded a better safeguard against attacks instinct with malignity and spiced with shameless impertinence. . . . Since Lord Brougham assailed Dr. Young, the world has seen no such specimen of the insolence of a shallow pretender to a master in science as this remarkable production, in which one of the most exact of observers, most cautious of reasoners, and most candid of expositors, of this or any age, is held up to scorn as a 'flighty' person who endeavors to 'prop up his utterly rotten fabric of guess and speculation', and whose 'mode of dealing with nature' is reprobated as 'utterly dishonorable to natural science'. And all this high and mighty talk, which would have been indecent in one of Mr. Darwin's equals, proceeds from a writer whose want of intelligence, or of conscience, or of both, is so great, that, by way of an objection to Mr. Darwin's views, he can ask, 'Is it credible that all favorable varieties of turnips are tending to become men'; who is so ignorant of paleontology that he can talk of the 'flowers and fruits' of the plants of the Carboniferous epoch; of comparative anatomy, that he can gravely affirm the poison apparatus of venomous snakes to be 'entirely separate from the ordinary laws of animal life, and peculiar to themselves'; of the rudiments of physiology, that he can ask, 'what advantage of life could alter the shapes of the corpuseles into which the blood can be evaporated?' Nor does the reviewer fail to flavor this outpouring of incapacity with a little stimulation of the *odium theologicum*. Some inkling of the

history of the conflicts between astronomy, geology, and theology leads him to keep a retreat open by the proviso that he cannot 'consent to test the truth of natural science by the word of revelation', but for all that he devotes pages to the exposition of his conviction that Mr. Darwin's theory 'contradicts the revealed relation of the creation to its Creator', and is 'inconsistent with the fullness of His glory'."

I have quoted at some length because this description of the article gives one a fair idea of its character and also of the strong feeling it aroused among Darwin's friends. These various fulminations had created an electric atmosphere for the meeting of the British Association at Oxford in the last days of June 1860. It was known that Wilberforce had written an article against Darwin in the current 'Quarterly' and it was rumored that attempts would be made to attack Darwin's theory in such a way as to discredit it in the eyes of the public. Indeed, Huxley, anticipating an appeal to the prejudice of a mixed audience, including ladies, had intended to leave Oxford after the opening session of the Association, but he was urged by Robert Chambers, the author of 'Vestiges of Creation', not to desert his friends. So he stayed. Two papers in Section D gave Darwin's enemies an opening for attack. On Thursday, June 28, a paper was read by a Dr. Daubeny 'On the final causes of the sexuality of plants, with particular reference to Mr. Darwin's work on the origin of species'. The President, Professor J. S. Henslow, asked Huxley to speak, but he declined, on the ground that a general audience so swayed by sentiment was not suited for the scientific discussion of such a subject. However, Owen did not hesitate to enter the lists. He said that he "wished to approach the subject in the spirit of the philosopher" and declared "his conviction that there were facts by which the public could come to some conclusion with regard to the probabilities of the truth of Mr. Darwin's theory". Thereupon, as one of his facts, he stated that the brain of the gorilla "presented more differences, as compared with the brain of man, than it did when compared with the brains of the very lowest and most problematical of the Quadrumana", that is, there were anatomical differences not merely of degree but of kind between the brain of man and that of the highest ape. The audience accepted the announcement as a smashing blow at the theory of descent. It happened, however, that this was a point that Huxley had investigated most carefully during the two years previous, coming to a conclusion precisely opposite, and in accord with earlier investigators. He gave Owen a "direct and unqualified contradiction", and pledged his reputation to "justify that unusual procedure elsewhere". This pledge he fulfilled to the hilt in the following year in the pages of the 'Natural History Review' and in public lectures. Owing to the prominent position taken by Huxley, against his wish, at this session of Section D, it was to him that Bishop Wilberforce directed his sarcasm two days later. Samuel Wilberforce, the Bishop of Oxford, nicknamed 'Soapy Sam' by his enemies, appears to have been eloquent, but shallow; al-

though lacking precise knowledge in letters or science, he did not hesitate to assume leadership of the clerical party in the battle of the species; armed with a little natural history picked up from Gosse and a few anatomical facts gleaned from Owen, he had the effrontery to challenge such earnest students of nature as Darwin and Huxley. On Saturday, June 30, Dr. Draper of New York presented a paper on 'The Intellectual Development of Europe considered with reference to the views of Mr. Darwin'. This paper was not remarkable, but it was known that the Bishop was going to use it as a text for his eloquence, so members of the Association came in such numbers to the meeting that it had to adjourn to a larger room, into which more than 700 people managed to crowd. Even the windows, by which the room was lighted along one side, were banked with ladies, fluttering with excitement. On the opposite side, between the two doors, was the platform, on which sat the president of the section, Professor Henslow; on his right was the Bishop; beyond him were Dr. Draper and others; on the president's left were Sir Joseph Hooker, Sir John Lubbock, Professor Beale, and Huxley. In the centre of the room sat a group of the clergy, who shouted for the bishop; in a corner stood a knot of undergraduates, including John Richard Green, the future historian, ready to cheer the Darwinians. For an hour Dr. Draper droned out his paper, turning first to the right and then to the left, as he made various references to the 'Origin of Species'. "Air we a fortioitons concourse of atoms?" he asked as he sat down. After him came a layman, who, in stentorian tones, let off his theological steam. Then a thin voice echoed him in more scholarly fashion. Third, a Mr. Dingle undertook to prove that Darwin made a fatal blunder in not consulting him, the speaker. Turning to the blackboard he proceeded to demonstrate. "Let this point A be maun, and let that point B be the mawnkey". He went no further; derisive shouts of "mawnkey" put a summary end to his disquisition. At this stage of the proceedings the president announced that none except those having valid arguments to bring forward would be allowed to address the meeting. There were calls for the bishop, but he rose only to state that he understood his friend Professor Beale had something to say first. Beale, an excellent histologist, said that the new theory ought to meet with fair discussion, but he added, modestly, that he himself had not sufficient knowledge to discuss the subject adequately. Then the bishop rose to make his famous speech. It was evident that he had been cramméd for the occasion, he used the arguments of his 'Quarterly' article, he ridiculed Darwin bitterly and Huxley savagely, but all in such dulcet tones, with so persuasive a manner, and with such well-turned periods that he gave keen pleasure to most of those present. For half an hour he spoke with inimitable spirit, emptiness, and unfairness. In a light scoffing tone, florid and fluent, he assured his hearers that there was nothing in the idea of evolution; rock-pigeons were what rock-pigeons had always been. Then turning to Huxley with a smiling insolence, he asked, was it through

his grandfather or his grandmother that he claimed his descent from a monkey? Huxley realized instantly the tactical blunder of this vulgar descent into personalities. Turning to a friend sitting next to him, and striking his hand emphatically on his knee, he said "The Lord hath delivered him into my hands". The bishop sat down amid loud applause, led by his clerical friends, while from the opposite side of the room the ladies waved their white handkerchiefs rapturously. Huxley rose slowly and deliberately. He was only 35. Slight in figure, pale and stern in face, quiet and grave in manner, cool and scientific in utterance, he made a retort that still rings through the halls of philosophy. After setting a good example by demonstrating his case with evidence, refuting Owen, Huxley turned to the bishop and said:

"I have asserted—and I repeat—that a man has no reason to be ashamed of having an ape for his grandfather. If there were an ancestor whom I should feel shame in recalling it would rather be a *man*—a man of restless and versatile intellect—who, not content with an equivocal success in his own sphere of activity, plunges into scientific questions with which he has no real acquaintance, only to obscure them by an aimless rhetoric, and distract the attention of his hearers from the real point at issue by eloquent digressions and skilled appeals to religious prejudice."

It remains to record that 34 years later, in the same city of Oxford, Lord Salisbury, a rigid High Churchman, in his presidential address before the British Association, said:

"Few now are found to doubt that animals separated by differences far exceeding those that distinguish what we know as species have yet descended from common ancestors . . . Darwin has, as a matter of fact, disposed of the doctrine of the immutability of species."

From that day Huxley became the apostle Paul of the Darwinian movement; by his essays, lectures, and studies, continued to the end of his life, he endeavored to convince, and succeeded in convincing, the intellectual world. He left his impress upon his own generation and upon those after him. He influenced the men that influence the thought of our own day. Through them his mind is active still.

The other event in his life that I venture to describe came near the end, in 1893, when he delivered the Romanes lecture, on 'Evolution and Ethics', at Oxford. A lectureship had been founded by J. G. Romanes, a zoologist and professor of Oxford. In 1892 Gladstone delivered the first of this series. It is worthy of note that at one time it looked as if Gladstone might be prevented from lecturing, whereupon Romanes asked Huxley to be prepared to step into the breach. He replied: "I am afraid that age hath not altogether cleared the spirit of mischief out of my blood; and there is something so piquant in the notion of my acting as substitute for Gladstone that I will be ready if necessity arise". It will be remembered that six years earlier (in 1886) he had crossed swords in controversy with the famous English statesman, when that great exponent of

British orthodoxy endeavored laboriously to reconcile the story of creation in 'Genesis' with the evidence of geology. However, Gladstone did deliver his lecture, so that Huxley's turn came the year after.

He was embarrassed by the fact that, by the terms of the foundation, both politics and religion had to be eschewed. In his careful avoidance of these topics he was compelled, as he said, to execute an 'egg-dance'; but there were no signs of difficulty in his exposition. On the afternoon of May 18, 1893, he faced a brilliant throng in the Sheldonian theatre. It was a great contrast to the meeting in the Museum thirty-three years previously, when as a young man he had championed the cause of science before a hostile audience. Then he was just becoming known as an exponent of Darwinism; now, largely by his own efforts, the theory he upheld had become an integral part of human thought, and he himself was the honored guest of the university. A year before he had been made a member of the Privy Council; he was the Right Honorable Thomas Henry Huxley, after having refused other, simply titular, honors. In the academic theatre there was assembled the best thought of England. Graduates from distant parts had come to hear him and every member of the University that could gain admission was there to follow his every word with the deepest respect. The press of the world was fully represented and as eager to report his lecture as if he were the leader of a nation about to utter a historic pronouncement. Although he was still feeling the effects of an attack of influenza and his voice had not its usual resonance, he rose to the occasion with his old unconquerable spirit. He looked splendid in his D. C. L. robes, with the silver-gray hair sweeping back from his fine forehead, the leonine squareness of his features tempered by the benignity of old age, and the glaze of his deeply set eyes softened by the common joys and sorrows of a long life. His lecture dealt with the antagonism between the cosmic process of nature and the ethical progress of man; the forces of wild nature and the products of sentient humanity; the jungle against civilization. He insisted that the ethical systems based on the principle of cosmic evolution were logically unsound. The doctrine of "biological necessity" brought forward by the Prussian seven years ago was a direct contradiction to Huxley's philosophy as expressed in this famous lecture. As he said, humorously, "My lecture was really an effort to put the Christian doctrine, that Satan is the Prince of this world, upon a scientific foundation." He believed that evolution accounted for morality, but he denied that the principle of evolution in general could be adopted as an ethical guide. In an earlier essay he had said: "The notion that the doctrine of evolution can furnish a foundation for morals seems to me to be an illusion that has arisen from the unfortunate ambiguity of the term 'fittest' in the formula, 'survival of the fittest'. We commonly use 'fittest' in a good sense; with an understood connotation of 'best'; and 'best' we are apt to take in its ethical sense. But the 'fittest' to survive in the struggle for existence may

be, and often is, the ethically worst." I quote the conclusion of his lecture:

"Much may be done to change the nature of man himself. The intelligence which has converted the brother of the wolf into the faithful guardian of the flock ought to be able to do something towards curbing the instincts of savagery in civilized men. But if we may permit ourselves a larger hope of abatement of the essential evil of the world than was possible to those who, in the infancy of exact knowledge, faced the problem of existence more than a score of centuries ago, I deem it an essential condition of the realization of that hope that we should cast aside the notion that the escape from pain and sorrow is the proper object of life. We have long since emerged from the heroic childhood of our race, when good and evil could be met with the same 'frolic welcome'; the attempts to escape from evil, whether Indian or Greek, have ended in flight from the battlefield; it remains to us to throw aside the youthful overconfidence and the no less youthful discouragement of nonage. We are grown men, and must play the man

'strong in will

To strive, to seek, to find, and not to yield,'

cherishing the good that falls in our way, and bearing the evil, in and around us, with stout hearts set on diminishing it. So far, we all may strive in one faith towards one hope:

"It may be that the gulfs will wash us down,
It may be we shall touch the Happy Isles,
. but something ere the end,
Some work of noble note may yet be done.' "

Seventeen years later, on June 7, 1910, the Romanes lecturer was Theodore Roosevelt. I heard him address a crowded audience in the same place on the subject of 'Biological Analogies in History'. He compared the cycles of animal life with those of national life. He sketched the geologic history of South America. He drew analogies between the fate befalling the forms of animal life and the destinies of the great artificial civilizations. He compared Rome and Britain; the British empire and the American democracy. He dressed the eternal verities in the garments of his own manly sincerity and gave them the freshness of his own personality. It was a great occasion in Theodore Roosevelt's life, and as I listened to him with warm interest and sympathy, I recognized that his character resembled that of Huxley in its essential manliness, in its high moral courage, in its invincible combativeness. When Huxley arrived in the harbor of New York on his visit to this country in 1876 and watched a tug hard at work in its purposeful way, he exclaimed, "If I were not a man, I think I should like to be a tug". One can imagine Roosevelt saying that. They were both like forceful steam-tugs amid the noisy traffic of life.

At the time of his American visit Huxley delivered the inaugural address at the opening of Johns Hopkins University. On that occasion he spoke on university education, and concluded as follows:

"I constantly hear Americans speak of the charm which our old mother country has for them, of the delight with which they wander through the streets of ancient towns, or climb the battlements of medieval strongholds, the names of which are indissolubly associated with the great epochs of that noble literature which is our common inheritance; or with the blood-stained steps of that secular progress by which the descendants of the savage Britons and of the wild pirates of the North Sea have become converted into warriors of order and champions of peaceful freedom, exhausting what still remains of the old Berserk spirit in subduing nature, and turning the wilderness into a garden. But anticipation has no less charm than retrospect, and to an Englishman landing upon your shores for the first time, traveling for hundreds of miles through strings of great and well-ordered cities, seeing your enormous actual, and almost infinite potential, wealth in all commodities, and in the energy and ability which turn wealth to account, there is something sublime in the vista of the future. Do not suppose that I am pandering to what is commonly understood by national pride. I cannot say that I am in the slightest degree impressed by your bigness, or your material resources, as such. Size is not grandeur, and territory does not make a nation. The great issue, about which hangs a true sublimity, and the terror of overhanging fate, is what are you going to do with all these things? What is to be the end to which these are to be the means? You are making a novel experiment in politics on the greatest scale which the world has yet seen. Forty millions at your first centenary, it is reasonably to be expected that, at the second, these States will be occupied by two hundred millions of English-speaking people, spread over an area as large as that of Europe, and with climates and interests as diverse as those of Spain and Scandinavia, England and Russia. You and your descendants have to ascertain whether this great mass will hold together under the form of a republic, and the despotic reality of universal suffrage; whether state rights will hold out against centralization, without separation; whether centralization will get the better, without actual or disguised monarchy; whether shifting corruption is better than a permanent bureaucracy; and as population thickens in your great cities, and the pressure of want is felt, the gaunt spectre of pauperism will stalk among you, and communism and socialism will claim to be heard. Truly America has a great future before her; great in toil, in care, and in responsibility; great in true glory if she be guided in wisdom and righteousness; great in shame if she fail. I cannot understand why other nations should envy you, or be blind to the fact that it is for the highest interest of mankind that you should succeed; but the one condition of success, your sole safeguard, is the moral worth and intellectual clearness of the individual citizen. Education cannot give these, but it may cherish them and bring them to the front in whatever station of society they are to be found; and the universities ought to be, and may be, the fortresses of the higher life of the nation."

It is assumed by those in contact with Huxley's philosophy that he was irreverent and the avowed enemy of religion. At one time he and his friends were anathema to orthodox church people on account of his advocacy of scientific method in all branches of human thought including religion. He believed scepticism to be the highest duty and blind faith to be the one unpardonable sin. "Logical consequences are the scarecrows of fools and the beacons of wise men." In order to describe his philosophic attitude, he adopted the term 'agnostic': "Most of my colleagues in the Metaphysical Society were 'ists' . . . and I, the man without a rag of a label . . . took thought and invented what I conceived to be the appropriate title of 'Agnostic'. It came into my head as suggestively antithetic to the 'gnostic' of church history, who professed to know so much about the very things of which I was ignorant."

He engaged in a number of lively controversies over the miracles recorded in the Bible, crossing swords with Gladstone and the Duke of Argyll, for instance, over the story of the Gadarene swine. He and Gladstone fought over the authenticity of the story of creation as told in 'Genesis'. In the course of this controversy he said:

"The antagonism of science is not to religion, but to the heathen survivals and the bad philosophy under which religion herself is often well nigh crushed." In 'An Apologetic Irenicon', published in 1892, he said:

"It is the secret of the superiority of the best theological teachers to the majority of their opponents that they substantially recognize these realities of things, however strange the forms in which they clothe their conceptions. The doctrines of predestination, of original sin, of the innate depravity of man and the evil fate of the greater part of the race, of the primacy of Satan in this world, of the essential vileness of matter, of a malevolent Demiurgis subordinate to a benevolent Almighty, who has only lately revealed himself, faulty as they are, appear to me to be vastly nearer the truth than the 'liberal' popular illusions that babies are all born good, and that the example of a corrupt society is responsible for their failure to remain so; that it is given to everybody to reach the ethical ideal if he will only try; that all partial evil is universal good, and other optimistic figments, such as that which represents Providence under the guise of a paternal philanthropist, and bids us believe that everything will come right (according to our notions) at last."

In conversation he remarked: "Religions come and go, but religion remains". He was reverent in mind, sympathetic in spirit, and of a lovable disposition to his friends. One of the most characteristic of intellectual exchanges was the correspondence between Charles Kingsley and Huxley on the occasion of the death of the latter's little son, his first-born. Kingsley wrote most feelingly and kindly, offering him the consolations of orthodox Christianity. Huxley replied in a long letter stating his position frankly. He was honest with himself. Speaking of the irregularities of his youth, he wrote: "What do I find to have been the agents of my

redemption? The hope of immortality or of future reward? I can honestly say that for these fourteen years such a consideration has not entered my head. No, I can tell you exactly what has been at work. 'Sartor Resartus' led me to know that a deep sense of religion was compatible with the entire absence of theology. Secondly, science and her methods gave me a resting-place independent of authority and tradition. Thirdly, love opened up to me a view of the sanctity of human nature, and impressed me with a deep sense of responsibility."

Tennyson in his autobiography records a visit from Huxley, and says of him: "He was chivalrous, wise, and earnest, so that one could not but enjoy talking with him". Yes indeed, he was chivalrous, generous, kind, belligerent, intolerant of humbug, a hater of shams. Above everything he had the intellectual courage that glorifies the true leader among men. No weight of authority could alter a conclusion to which he had come in logical consequence of fact, observation, and thought. This courage made him the captain of the forces that fought for the theory of evolution at its birth; it was the natural expression of an intellectual honesty that was invincible, as is shown in his correspondence with Kingsley; by aid of it he emancipated the religious no less than the scientific thought of his day and generation.

In 1870 he was elected a member of the London School Board and took a prominent part in the proceedings. His colleagues "soon found", as Dr. J. H. Gladstone records, "proof of his great energy, and his power of expressing his views in clear and forcible language; but they also found that with all his strong convictions and lofty ideals he was able and willing to enter into the views of others, and to look at a practical question from its several sides". He advocated the retention of the Bible in the schools; "he had", as P. C. Mitchell says, "the inevitable respect of an Englishman for the English Bible as one of the greatest books in our language"; moreover, he thought that "the mass of the people should not be deprived of the one great literature which is open to them, nor shut out from the perception of its place in the whole past history of civilized mankind". To this I venture to add, that no man desiring to acquire skill in the use of our language can afford to neglect that well of English undefiled, the King James version of the Bible. He set an example to men of science by recognizing his duties to society and his obligations to the community in which he lived. Not content to be merely a keen student of science, he was also a zealous citizen, willing to take part in the social movements of his time, giving to them the aid of his special knowledge and method of research. He served on ten Royal Commissions for the collection and examination of evidence needed for intelligent legislation. He was a member of the London School Board, as we have seen. He illuminated public questions by addressing large audiences; he contributed discussions and criticisms to the reviews; he was much more than a scientific specialist, he was a social philosopher of the most potent kind. He brought the rare skill of a scientific expositor to current affairs and familiarized his

contemporaries in every walk of life with the value of scientific method. In one of his addresses, for example, he said:

"The vast results obtained by Science are won by no mystical faculties, by no mental processes other than those which are practised by every one of us, in the humblest and meanest affairs of life. A detective policeman discovers a burglar from the marks made by his shoe, by a mental process identical with that by which Cuvier restored the extinct animals of Montmartre from fragments of their bones. Nor does that process of induction and deduction by which a lady, finding a stain of a peculiar kind on her dress, concludes that somebody has upset the inkstand thereon, differ in any way, in kind, from that by which Adams and Leverrier discovered a new planet."

It remains to quote several characteristic utterances of Huxley. We are still debating what are the essentials of a liberal education and we continue to change the curricula in our colleges in an effort to give the youth of our country the best preparation for life. On this subject, as on many others vital to human progress, Huxley had clearly defined ideas. In an address to the South London Working Men's College, in 1868, he said:

"That man, I think has had a liberal education who has been so trained in youth that his body is the ready servant of his will, and does with ease and pleasure all the work that, as a mechanism, it is capable of; whose intellect is a clear cold-logic engine, with all its parts of equal strength, and in smooth working order; ready, like a steam-engine, to be turned to any kind of work, and spin the gossamers as well as forge the anchors of the mind; whose mind is stored with a knowledge of the great and fundamental truths of Nature and of the laws of her operations; one who, no stunted ascetic, is full of life and fire, but whose passions are trained to come to heel by a vigorous will, the servant of a tender conscience; who has learned to love all beauty, whether of Nature or of art, to hate all vileness, and to respect others as himself."

On the last day of 1860, musing over his future, he made an entry in his journal, describing his aim in life.

"To smite all humbugs, however big; to give a nobler tone to science; to set an example of abstinence from petty personal controversies, and of toleration for everything but lying; to be indifferent as to whether the work is recognized as mine or not, so long as it is done."

He was then 35. In his old age he looked back and spoke of the objects he had had in view, as follows: "To promote the increase of natural knowledge and to forward the application of scientific methods of investigation to all the problems of life to the best of my ability, in the conviction, which has grown with my growth and strengthened with my strength, that there is no alleviation for the sufferings of mankind except veracity of thought and of action, and the resolute facing of the world as it is when the garment of make-believe by which pious hands have hidden its uglier features is stripped off."

He died in 1895, at the age of 70, his work done. On

his tombstone there were inscribed, by his own request, three lines from a poem written by his wife:

"Be not afraid, ye waiting hearts that weep;
For still He giveth His beloved sleep,
And if an endless sleep He wills, so best."

I might end on this sad note, but to do so would not be in harmony with the moral of the Huxley story. The dominant note of his life was not melancholy; it was vibrant with virile courage, with the essential spirit of true manhood. To the young men in an industrial centre such as Butte, to the graduates about to start on their career as mining engineers, I commend Huxley's life and teaching as a tonic to their moral fibre; it should cause them to appreciate the fact that man does not live by bread alone, and that a bread and butter dependency is not the sole object of education, whether it be scientific or classical. I have quoted his splendid description of a liberal education. He fulfilled his own teaching. He exemplified the workings of a spirit nurtured in the dry bracing air of scientific thought. He was the exponent of veracity in thought and in action; he demonstrated the tremendous value to the community, particularly to a democratic community, in which ideas are freely uttered, of intellectual honesty. The possession to a superlative degree of this quality made him greatly useful in his day and generation; it also made him happy. His was a life joyous in its splendid independence and forcefulness. He had a sincerity of mind that some of us would please ourselves by calling it American. I commend it to you who are about to set out in life as a priceless quality. It belonged to Alexander Hamilton, to Theodore Roosevelt, and to the greatest of all truly great men, Abraham Lincoln. Intellectual honesty is the first requisite of a scientific mind; it is the touchstone of real independence.

"This above all; to thine own self be true,
And it must follow, as the night the day,
Thou canst not then be false to any man."

Aluminum

The expansion of aluminum-plant capacity in the United States has been continued as the development of hydro-electric power near Marysville, Tennessee, and Badin, North Carolina, has increased the power available, states a U. S. Geological Survey bulletin. Experiments of the Anaconda Copper Co., which has been under way for some time at Great Falls, Montana, resulted in the production of aluminum early in 1921, though not on a commercial basis. It is reported that a San Francisco company has under contemplation the development of an extensive water-power on Klamath river which is to be used for the manufacture of aluminum.

The French aluminum industry has been brought into closer control by the purchase of the Société électro-métallurgique française by the Compagnie d'Alais. The combination, which has a capital of 130,000,000 francs, will control 90% of the French aluminum-producing

capacity and has extensive holdings in the Italian and Norwegian aluminum plants. Information is now available concerning the production of aluminum in France for the war period. The official figures are as follows:

Aluminum Produced in France, 1913-1919, in Metric Tons				
1913	13,483	1917	11,064
1914	9,063	1918	10,010
1915	6,017	1919	10,525
1916	6,601		

The production of aluminum in Norway in 1919 was 3120 metric tons, as compared with 6834 tons in 1918 and 7600 tons in 1917. The aluminum works of Norway are the Tyssedal and d'Eydehavn plants of Det Norske Nitrit Ak, the Høyang plant of the Norsk Aluminum Co., and the Vigeland and Stangfjord plants of the A. S. Vigelands Brug. The experiments of the Norsk Aluminum Co., in connection with the extraction of aluminum from labradorite, have not yet met with commercial success.

The probable annual capacity of the German aluminum industry is between 25,000 and 40,000 tons, probably nearer the lower estimate. A large part of the German industry uses lignite for power, which would hardly seem to warrant the belief that it can long survive a return to more normal conditions. The war contract of the German government for aluminum with the Swiss Aluminum Industrie A. G., of Neubausen, was finally canceled by payment of 11,000,000 Swiss francs to the company. The production of aluminum in Italy in 1919 was 1673 metric tons, as compared with 1715 tons in 1918.

The economic conditions in Mexico are summarized in a consular report as follows:

(1) A refunding of perhaps \$75,000,000 of defaulted bonds, plus some \$30,000,000 of accrued interest, a funding of foreign damage claims of at least \$50,000,000, and a substantial increase of the net revenues of the Government, to provide service on all this, are essential for the near future. The currency system is dangerous in its rigidity, but steps are being taken to reform it.

(2) An almost complete new banking system has to be built, and it is hoped to insert in it desirable features of the American reserve system.

(3) Under existing currency and banking systems, the question of foreign exchange enters little into commercial questions.

(4) The normalization of prices is proceeding more slowly and more irregularly than in the United States. Local manufacturers are prosperous.

(5) Labor is much cheaper in Mexico than in the United States, but readjustment is yet taking place in most lines. Unemployment is serious. There remains danger of disaster from radical agitation, but it is diminishing.

(6) Production costs have not yet been fully adjusted, and tariff action may tend to hold them up.

(7) All trade is dull, and the condition will be corrected only by an improvement in world commodity markets and greater confidence in the maintenance of stable government.

Status of the Metal Mining Industry: An Interrogatory

In order to obtain trustworthy information on the present status of mining, the business department of the 'Mining and Scientific Press' recently issued an interrogatory to a number of engineers who are qualified to testify on the subject. The following sent answers:

Walter H. Aldridge	E. A. Julian
Charles Boeking	John G. Kirehen
F. W. Bradley	P. C. Knapp
L. S. Cates	Robert Linton
J. Parke Channing	William J. Loring
Charles A. Chase	W. G. McBride
David Cole	Seeley W. Mudd
George E. Collins	J. Nelson Nevins
M. J. Dailey	William A. Ogg
James S. Douglas	W. B. Phelps
Walter Douglas	L. D. Ricketts
Karl Eilers	George A. Stahl
A. B. Foote	George W. Starr

H. I. Young

It will be seen that the list is thoroughly representative. We are not at liberty to publish the letters as received from these gentlemen, but we give their replies seriatim, feeling sure that the information is timely and interesting.

GOLD

Question 1: Is gold mining expanding by reason of the general lowering of the cost of production?

"Yes, slowly and gradually in the Cripple Creek district."

"Yes, but very little. Decreased cost of production is too little to have had effect."

"Not to our knowledge."

"No. I see no signs as yet of any revival of interest in gold mining either as concerns the development of new properties or the bringing into production of gold mines already developed but idle."

"There has been some expansion, due to a general lowering of cost of material and labor, but it is my belief that the chief cause of interest shown of late in gold

mining is due to a stagnation of the base metals market. Those that have been driven from the base metals are seeking other fields; oil for some time absorbed most of this interest, but at present some interest is being turned to gold mining. The slight reductions in mining costs are not large enough to make gold mining attractive. In fact, my costs are higher than at any time during the history of the mine. This is due partly to conditions in the mine itself; but mainly due to high freight-rates which greatly affect our costs of power."

"No; with the exception that in the Cripple Creek district there is some increase in tributing, due to work being unobtainable in other lines."

"I do not know that I can say that the expansion of gold mining has been apparent yet. There seems little doubt, however, that the gradual reduction in cost of operation will cause such an expansion. Another reason for expansion will probably be the fact that in the future money will be more plentiful for such work, because the profits to be derived from industrial work have decreased and capital will be seeking the greatest return and will probably be attracted by the possibilities of mining."

"The — mine is resuming operations in full, after operating at less than 50% for 16 months, although costs are still 30% above 1914."

"To date there is no apparent expansion, but I believe that the next few months will show a slight improvement in this direction."

"Yes—prospecting."

"Some new work has actually started, and there is much conversation concerning plans for future work, most of which may not be carried out unless further substantial reductions occur in operating costs."

"Yes."

"The only strictly gold camp that I am now at all familiar with is Cripple Creek, and there gold mining is expanding, by reason of general lowering of costs of production."

Question 2: Have the gold mines in your district that were shut-down by reason of high operating costs during the War period resumed activity?

"Yes—to a moderate extent."

"No. Only four mines worked on company account during the War. Reports are that one company, the —, is to resume on September 1. Otherwise, not a single property has opened since the War, except a few in a desultory way by lessees."

"No."

"None of them has resumed."

"Up to the present writing none of the properties in this district that were closed down due to high operating costs has resumed operations. Costs have not been greatly reduced, although labor has been reduced \$1 per shift for all classes. Our main item tending to high costs is the production of power. Freight reductions would help us more than anything else."

"No."

"No productive mines have been shut-down so far as I know. The amount of prospecting and developing has decreased, however."

"Some of them."

"No."

"Not generally."

"During the War this office closed four gold properties, due to a combination of high costs and constantly decreasing value of ore. The daily gross production was, roughly, as follows:

A—700 tons @ \$9 per ton.....	\$6300
B—400 " " 4 " "	1600
C—300 " " 5 " "	1500
D— 40 " " 12 " "	500

"'A' has resumed on basis of 50 tons per day at \$15, and 'D' is just started at previous rate, both totaling \$1100 per day gross production. 'B' and 'C' have been dismantled.

"One gold prospect receiving development at outbreak of war, was closed and work not yet resumed. Should costs continue to decline, work will be started during the coming year."

"No."

"One silver-gold-lead mine in the Telluride district, the —, is attempting resumption. It is presumed to have shut-down because of generally adverse conditions."

Question 3: Should the McFadden Bill fail to pass, will it seriously affect gold mines and militate against prospecting and development of new properties?

"Yes, I certainly think so."

"Yes."

"No. Passage of this bill would temporarily stimulate but not build up the industry. During the War, when prices of everything except gold were artificially raised, it would have been just and equitable to have passed such a law. But now that the worst is over, gold mining will be on a firmer basis if left to pick up gradually, rather than to be given the temporary stimulus of this bill, only to be inevitably followed by reaction that would be disastrous and might become fatal to the industry. The subject is too long to be discussed here, but such 'special privilege' legislation as this is never desirable as a political policy, and the present depression is largely the result of recovery from special privilege laws and conditions during the War."

"If the McFadden Bill fails to pass, it will most seriously affect prospecting, or, I should better say, that the passing of this bill would undoubtedly stimulate prospecting for gold. Also many gold mines throughout the country would again operate if the bill was passed; but the gold miner looks forward more to the reduction of costs than to protection. Freight-rates must be materially lowered for us to exist much longer."

"Yes; unless, as I anticipate, international conditions result in a premium on gold."

"The failure of the passage of the McFadden Bill would leave things as at present. If it should pass there would be a very marked increase in prospecting and development of new properties."

"We are not counting very much on the passage of this bill. We naturally would like to see it passed."

"Should the McFadden Bill fail to pass it would not seriously affect existing gold mines, because to a slight degree the reduction of operating costs will compensate for a part of the benefit that would be derived by the passage of the McFadden Bill and to a very great extent the failure of the McFadden Bill, or some similar legislation having for its purpose the relief of the gold producer, to pass, prospecting and development of new properties will suffer a handicap. In my own particular case, I have opened and ready for stopping a million tons of ore that is not payable under present operating costs, but these reserves would be highly productive if the McFadden Bill or some other legislation were passed to give relief that the McFadden Bill proposes."

"Yes."

"Failure of the McFadden Bill to pass will not affect our plans, since we have never considered it had a chance."

"No, because under present market conditions, speculators would furnish any amount of money for a good gold mining proposition. Gold is in legitimate demand as a standard of value, and this demand should not be 'monkeyed' with or jeopardized by a 'smart-alec' effort to secure a subsidy for the gold-mining industry. In other words, the gold miners should let well enough alone. There are not many commodities that can now-a-days be marketed so easily as gold is marketed."

"The coming months will be more painful, but the ultimate readjustment will be healthier; with a healthy readjustment, I doubt that prospecting will be hurt or that new properties will fail of development."

Question 4: Are the managers of existing properties considering ways and means of reducing operating costs through the installation of more modern and more economical equipment?

"Yes, to as great an extent as possible."

"Yes."

"Yes."

"My observation has been that the *managers* are always seeking ways to reduce costs, but in many cases they are restrained from making improvements by the demand for immediate dividends."

"Managers of existing properties do look forward to a reduction of costs by use of modern equipment, and most gold mines are quite well equipped with modern machinery."

"Actual mining costs, that is, breaking, tramming, etc., as compared with reduction costs (metallurgical) are higher now than in pre-war times. In other words, the main chance for cost reduction lies in the mine rather than in the mill. Gold-bearing veins, with a few exceptions, are narrow and require underground mining methods that are expensive. If large low-grade properties could be found, the chances for low costs would be realized, as has been the case in copper mining."

"They are considering all possible means, but without prospects of material results, excepting in a few non-typical instances."

"Always, I think."

"We are always looking for improvements, but are not contemplating any important installations now."

"I cannot answer for other operators, but in my case

I have, in the face of the high cost of machinery during and since the War, installed labor-saving devices which were made necessary for operating during the War period and the high operating cost period. Therefore, so far as my operations are concerned, I know of nothing that could be added that would reduce the cost of operating on my properties except the application of these up-to-date appliances in a more practical way. Each month shows an improvement in costs, mainly due to the co-operation on the part of my various operators to this one end."

"Yes; in every way to save labor."

"Yes. But are frequently limited in installation of more economical equipment, on account of the erratic ore occurrence and the small developed tonnage. This applies particularly to the gold mines of Nevada."

"Yes."

"I hope so; that seems to be their proper function, and should regret to see them recreant as a class."

Question 5: If the answer to No. 4 is 'Yes', please give such particulars as you can.

"Cannot record anything in detail at this time."

"By the substitution of electrical compressors for steam, if in the judgment of the management there is enough ore to justify it; better air-drills and the continuation of the Roosevelt Tunnel for drainage of the Vindicator group."

"Investigating improved gold-saving devices for dredges."

"Am not in touch with any activity in gold mining."

"I believe I have answered No. 5 under No. 4. I might add that large-scale production and consolidation of management would help a lot."

"An answer to this question depends so entirely on the circumstances concerning each individual mine that an adequate reply would occupy a volume."

"I know of no particular directions in which special effort is being made now."

"'A' has over one million tons of low-grade tailing that should yield a profit if cheaply handled. It is now equipped with a Radial wire-rope tramway, which cannot give desired capacity of 1000 tons in 16 hours. It is expensive in operation, and fails to efficiently clean the bottom layer without dilution with waste. The installation of other equipment is now being considered that will

more efficiently convey the tailing to the treatment plant already erected."

"Every operator of a profitable gold mine is on the alert to reduce operating cost and to increase metallurgical efficiency."

Question 6: What class of mining and milling machinery is least satisfactory in the performance of its function and in what respects should it be improved?

"This is too large a question to answer in a letter of this scope."

"In mining, better and cheaper air-drills. In milling, better and cheaper grinding-machinery."

"Does not lend itself to an easy answer from dredge operators."

"Power-generating machinery is the least satisfactory, though the trouble is often due to poor installation and poor attention to it while operating. There is room for improvement in power-generating machinery, both for efficiency and cost."

"In the mining end, improvements could be effected on mucking-machines, dust-allaying stoping drills, and ventilating-equipment and methods. In the mill, breaking and grinding-equipment, as most gold mines have to do fine grinding."

"Milling machinery is the least satisfactory in the performance of its function. This requires explanation. The simple act of crushing ore to a fine powder may be done in any sort of a grinding or stamping apparatus, and so long as there are no impurities mixed with the ore crushed it makes little difference what type of machine may be used, metallurgically, but economically, milling machinery should be such as to treat the largest tonnage per unit of crushing-plant, whether it be stamps, rolls, or ball-mills. For instance, my — mill is averaging nearly 19 tons per stamp. This has been made possible by the introduction of modern grinding-plant after the stamps, which was less expensive to erect and is less expensive to operate than the old type of stamp-mill that has been used in the past and is being used at the present time in various sections of our country."

"Another vital question that should receive attention is the rock-drilling plant on the mines. Efficient air-compressors sufficiently large to force air the required distance with the minimum of friction, minimum of loss through leakages, and the application of compressed air at economic pressure in the operation of a machine-drill of the latest type, should be installed. There are several that are not over three years old, and one or two that are not over a year old, that are certainly nearly the last word in drilling-machinery. Ventilation should be care-

fully watched, but in order to answer your question No. 6 fully it would be necessary to write at considerable length in order to point out the numerous departments of a mine that should receive detailed attention. They do not amount to a great deal singly, but collectively they mean considerable in the direction of operating costs, but I do not take it that this is what you are asking for."

"The shovel."

"Where mining and milling are dependent upon power from internal-combustion engines, the delays due to engine trouble may constitute the chief source of loss through decreased production and higher costs."

"Manufacturers are satisfactorily improving these machines, but they should more carefully ascertain the conditions under which their engines are to operate, and, in some instances, lower the horse-power rating so that overloads may be avoided."

"Dilution of ore in mining continues to be a large factor in raising costs through decreased production."

"Surface sorting aided by washing-machines would help many small gold mines. Present machines are bulky and expensive to operate, but, clumsy as they are, small operators are not fully educated as to their value."

"In cyaniding gold ores there are heavy losses in chemicals and soluble values, accompanied by high costs in dissolving and filtering."

"There appears to be special need for a machine that will satisfactorily combine the work of agitating and filtering."

"Ball-mills for a hard-rock low-grade gold-quartz mine. Such mills should be thrown out and replaced by stamps."

"The dry-stoping drill is heinous and its continued use will destroy present users and prevent proper recruiting for the industry in the future. Wet drills are developing slowly, but it may be necessary to compel their use."

Question 7: Is there a tendency to substitute mechanical for hand labor wherever possible and for what particular class of work?

"Yes—for tramming."

"Yes, of course, wherever possible, but the changes are so small from time to time that are possible to make, that it is hard to give particulars, outside of mechanical mucking-machines in the mines, and in milling we substitute everything new that comes up and is proven efficient."

"No."

"Not so much as in manufacturing. The mill is carefully designed to reduce hand labor to the minimum, but

the mine is neglected in this respect. It is rare to see a gold mine of any size in which there is not room for more mechanical methods of handling ore and waste underground.

"I think that the strong tendency of mining to fall into the hands of a few big operating companies, and the waning lack of interest on the part of the little fellow to take up and develop prospects is an unwholesome tendency in our national life. It is the reason for the fading out of the prospector."

"There is a tendency to substitute mechanical for hand labor and the greatest possibilities lie, in my opinion, in the development of mucking-machines. These machines must be small, light, and efficient; must be designed to be used in stopes, as many gold mines have to use a filled-stope method of mining, which requires a great deal of shoveling. Drag-line scrapers with small air-hoists have proved a great aid, but it is my opinion that a small, light, portable mucking-machine could be developed."

"Yes; all places. With mines of short life the difficulty is one of investment and the time required for its repayment through economies."

"We always are trying to eliminate hand labor."

"This is a most difficult question to answer, because the well-regulated mine, under close management, has in the past introduced mechanical for hand labor wherever possible and there is no more tendency at the present moment than there has been in the past to do this.

"I do not think it out of place to state here that a mechanical shoveling device, made cheap and light enough to be used in ordinary drifts where from 30 to 50 tons of muck is broken per 24 hours, which machine could be wheeled around on the ordinary car-track from one place to another, would fill a great want and expedite not only the development work but at the same time reduce the cost of this particular type of work.

"The great trouble is that all shoveling machines are too expensive, too cumbersome, and too heavy to be considered under the headings referred to above. A mechanical shoveling machine, such as the one I have referred to, would find a large field for operation, but the great trouble is that inventors are too elaborate in their ideas and too little attention is given to the economic side of the question to have provided up to the present time a machine that will serve a long-felt want, that is, in handling a small amount of muck broken from the face of a drift whose cross-section represents 6 ft. 6 in. by 7 ft. in the clear, with an advance of probably 4 ft. 6 in. per 24 hours. This is the type of machine we want."

"Shoveling."

"Yes, at every possible point, depending upon the

capital expenditures required and the ore-reserves over which such expenditures can be spread."

"Yes. For all classes, where opportunity offers."

(To be Continued)

Chromite

The only commercially valuable ore of chromium is chromite, states a U. S. Geological Survey bulletin. As the chromite in commercial ore is mixed with other minerals the ore rarely contains more than 55% of chromic oxide, and most of the ore now marketed contains about 50%. Chromium has many uses, largely as a constituent of chrome-steel. The chromium is introduced into the steel as ferro-chrome containing usually between 60 and 70% of chromium. A corrosion-resisting chrome-steel contains from 11 to 14% of chromium and not more than 0.45% of carbon. It strongly resists rusting and all forms of oxidation, even at high temperatures, and it is not corroded by many agents that attack ordinary steel, nor is it affected by nitric acid, though it is attacked by hydrochloric or sulphuric acid. Salt water, fruit juices, and ammonia have no effect on it. Although invented by an American, it was first used in England for cutlery. During the War it was used extensively for making the valves of internal-combustion engines, for which it is particularly suited, not only because it resists pitting but also because it retains its strength at high temperatures. Its physical properties are equal to those of ordinary steel and in some respects superior. The War delayed development because of the lack of chromite, but the use of the alloy should be increased materially, even in connection with structural work. It is usually known as 'stainless' steel.

Stellite is essentially an alloy of cobalt and chromium, to which is usually added a small quantity of tungsten to increase strength. Its composition varies as follows: Cobalt, 50 to 60%; chromium 30 to 40%; tungsten, 8 to 20%. It resists corrosion. Its hardness persists at high temperatures; during the War it was used in high-speed lathe tools employed for turning shell and ordnance. It is extensively used in the manufacture of surgical and dental instruments. Chromite is used as a refractory material, principally in the steel industry. It has been estimated that about 1½ lb. is consumed for each ton of steel made. Small quantities of chromite refractories are used in certain parts of furnaces for smelting copper and nickel. The chemical industry consumes a large quantity of chromite in making chromates and bichromates of soda and potash, and chromic acid. Before the War the tanning industry consumed about two-thirds of the chromium chemicals, but during the War the proportion was reduced to about one-half. In dyeing textiles chromium salts are used as mordants. The cloth is saturated with the mordant and then introduced into a bath of the coloring matter where a precipitate (lake) is formed on and in the fibre of the cloth. Chromium compounds are also used as pigments.

REVIEW OF MINING

SIGNIFICANT PURCHASE OF COPPER

The American Brass Co. has purchased approximately 5,000,000 lb. of copper for October and November delivery at 12½c. and has put out another inquiry for several million pounds additional at the same figure. The order for the 5,000,000 lb. went to several dealers, being distributed equally according to the importance of the selling interest and the ability of the seller to supply the metal when wanted. In the trade it is said that not all the dealers took part in the transaction and some are insisting that the American Brass Co. will find it impossible to secure much more of the metal at that figure. As a matter of fact virtually all the big sellers are quoting 12½ to 12¼c. for October delivery with a slight advance for later shipments and the fact that the American Brass Co. on the new inquiry wants November and December delivery is believed to be the reason that it will find difficulty in obtaining the metal at this figure. Several of the large sellers are unusually firm in their attitude on prices, and it is known that at least two refused to take any of the recent business of the American Brass Co. because they considered the price unsatisfactory. The American Brass Co. is the first of the large consumers to be in the market in months with the possible exception of the American Steel & Wire Co., which was a purchaser two months ago.

BETTER PRICE FOR SILVER HELPS THE MINES AT COBALT

Eight mines are producing silver in the Cobalt district. In the order of their importance, they are the Nipissing, Mining Corporation, Coniagas, O'Brien, La Rose, Bailey, Aladdin-Cobalt, and Hudson Bay. The increase in the price of bar-silver to close to 70c. per ounce in New York, which is equal to about 77c. in Canadian money, will cause a number of other mines to resume production provided the price shows reasonable signs of remaining at this high point. Among the present idle properties which could operate profitably with silver at 70c. per ounce are the Temiskaming, Beaver Consolidated, McKinley-Darragh, and possibly the Peterson Lake. Costs at the Nipissing have been reduced so as to average less than 35c. on each ounce of silver produced. This indicates a net profit of about 40c. per ounce on current output. The company will disburse a regular quarterly dividend of 3% on October 20 and with a surplus of close to \$4,000,000 is expected to pay a bonus of 3% with its January disbursement, as has been the custom in former years. High-grade ore being taken out of the O'Brien, Nipissing, and the Violet mine of the La Rose company compares favorably with the rich shoots which attracted widespread attention to the Cobalt district 15 years ago.

MINE TAXATION TO BE DISCUSSED AT THE MINING CONGRESS CONVENTION

Believing that a thorough discussion of taxation of mines by the various States—(1) existing laws, (2) principles, and (3) uniformity—by representatives of State governments and representatives of the wasting industries will serve a useful purpose, this subject has been selected by the Com-

mittee on Taxation for consideration at the Mine Tax Conference to be held under the auspices of the American Mining Congress at the convention to be held in Chicago from October 17 to 22. Invitations have been sent to the Governors of all the States to appoint special delegates to attend this conference, and the conference is open to all others interested in mine-taxation. Members of the American Mining Congress are urged to take up with the Governors of the States in which they operate the matter of having delegates appointed for this conference, which has for its primary aim the discussion and refinement of methods which will equalize, simplify, and lighten the growing tax burden, and thus stimulate the mining industry.

UNITED STATES SMELTING DECLARES REGULAR DIVIDEND ON PREFERRED STOCK

The United States Smelting Co. declared its regular quarterly dividend of \$7½c. per share on preferred stock, payable October 15. The directors issued the following statement:

"Consolidated earnings for the first eight months of this year are estimated at \$1,314,260 after providing all interest. There have been deducted from these earnings reserves of \$700,633 for depreciation and depletion and \$97,515 for further exploration work in Mexico. These reserves aggregate in all \$798,148 and leave estimated net earnings for the eight months of \$516,112, of which \$281,498 was earned in the half-year ending June 30. The preferred dividend requirements for the eight months period are \$1,134,816. In June and July, operations in Mexico were curtailed owing to decreased power-supply resulting from lack of rain, but these conditions are now improving and with increased tonnages and a somewhat higher price for silver the Mexican earnings are more satisfactory. The Bingham mines in Utah have continued operations steadily throughout the period and, notwithstanding the low price of lead, have earned enough to provide the usual reserves for depreciation and depletion in addition to showing a moderate net profit. The Midvale smelter and the lead refinery have continued operations at a reduced tonnage owing to the shortage of custom ores due to high mining, transportation, and smelting costs and the low price of metals, and until these conditions are bettered the operations cannot be considered as satisfactory. All metals are carried at 'market' and if the present moderate improvement in operating conditions continues for the next four months the company should end the fiscal year with but a moderate decrease, if any, in surplus after deducting full charges for depreciation, depletion, exploration, and the payment of the preferred dividend."

COMPLAINT AGAINST MINERALS SEPARATION IS AMENDED

The Federal Trade Commission has amended the complaint in the Minerals Separation case. The amendments do not vitally affect the complaint, being largely changes in construction, and it is generally thought that no additional collections of fact will be necessary. The most important of the amendments is that which charges that the defendants, by virtue of their alleged control of the patents in question, "are able to and do directly affect and exercise a direct con-

trol over interstate commerce" in the case of the ores and metals affected by the patents.

MINING IN UTAH IS BY NO MEANS 'DEAD'

F. C. Schramm, president of the Salt Lake Chamber of Commerce, announces that immediate action will be taken to discount misleading reports that have been circulated broadcast as to the present status of the mining industry in Utah. Mr. Schramm states that owing to the shut-down of the Utah Copper Company, the opinion seems prevalent that the mining industry in this State is in a "very depressed condition". This is far from the truth. He calls attention to the fact that the silver-lead mines in the Park City and Eureka districts are now employing more men than at any time in the past four years; that Utah is producing more silver than any other State in the Union, and still retains its place of being third in the production of lead. The Murray smelter is running four out of eight blast-furnaces; the United States smelter at Midvale is operating four out of six blast-furnaces. The Garfield smelter is producing an average of 10,000 oz. silver per day, although, naturally, its copper production is considerably below normal, owing to the Utah Copper Company being closed down. Taking everything into consideration, Mr. Schramm is of the opinion that Utah mining operations, as a whole, are more nearly normal than those of any other Western State.

LEACHING WITH SULPHUR DIOXIDE PROVES SUCCESSFUL

Tests on leaching with sulphur dioxide complex ores from the Miami district in Arizona have been completed at the South-West station of the U. S. Bureau of Mines at Tucson. It is considered that sulphur-dioxide leaching is a demonstrated success on the most refractory silicious ores in the South-West and also on ores containing a large percentage of acid-soluble gangue. The commercial application of the process appears to hinge largely upon the successful development of the manufacture of sponge-iron. Laboratory work is being done on Walker River silicious copper ore, which has soluble lime, iron, and manganese aggregating 10% acid-soluble gangue. The results obtained so far are encouraging.

IDAHO PREPARED TO ASSIST PROSPECTORS

Stewart Campbell, State Mine Inspector for Idaho, has added a new feature to the office that will add materially to its value to the prospector and the general public. A prospector must know the value of and the market for the ore or mineral sought or found, and as there is no convenient source available where he can find a marketing place for any of the uncommon ores or minerals, Mr. Campbell has prepared a complete list of the purchasers and users, in the United States, of the following metal and non-metal products, all of which are found in Idaho: Antimony, barytes, bauxite (aluminum), bismuth, cadmium, chromium (chrome ore), cobalt, diatomaceous earth, feldspar, fluor spar, fuller's earth, graphite, gypsum, magnesite, manganese, mica, molybdenum, nickel, platinum, pumice, rutilum, silica sand, sodium, talc, tin, titanium (rutile), tripoli, tungsten, uranium, and vanadium. Information concerning the purchasers or users of any particular mineral will be furnished on request to his office. With this information and the services of the Idaho Bureau of Mines and Geology, at Moscow, available for a qualitative determination of unknown minerals, the State has opened two avenues of assistance leading to the development of her mineral resources.

LOCAL SECTION OF THE INSTITUTE ENTERTAINS H. FOSTER BAIN

The Local Section of the A. I. M. & M. E. gave a dinner and smoker in honor of H. Foster Bain, Director of the

Bureau of Mines, on October 4. Mr. Bain and the members of his party, who are visiting the mining States of the West, spent three days in San Francisco and Berkeley, where the Bureau has an experiment station.

ARIZONA

Jerome.—At a recent meeting of the Arizona Chapter of the American Mining Congress the following resolutions were adopted:

Taxes

Whereas, a grave situation faces the mining industry from all angles, in that the present selling price of copper is 4c. per pound less than the average selling price based upon 10 years previous to the great war; that practically every cost attached to the mining industry has risen to a height entirely inconsistent with pre-war conditions; that the burden of taxation within the State of Arizona has become so heavy by reason of the tremendous expenditures being made for public purposes, resulting in the net cost for the taxation alone of 1.7c. upon every pound of copper produced; and

Whereas, if the present burden of taxation is maintained or increased, as seems to be the prospect now before us, there is grave danger that this factor of itself will prevent or greatly delay the resumption of mining operations, even under more favorable industrial conditions than are now present; now therefore be it

Resolved, that efforts shall be made by those interested in the mining industry to bring before the taxpayers of the State the serious problems now confronting the State, and endeavor in every way to influence all the boards or other officers having jurisdiction in the matter of public expenditures and conserving the money of the taxpayers, to the end that the present excessive rates shall be promptly and materially reduced, and that the present burden of taxation shall be lightened upon every class of property in the State.

Freight Rates

Whereas, the resumption of mining copper depends upon the sale of the product at a profit, and.

Whereas, the large items of expense in cost of production and marketing are freight-charges on mining machinery, material, and supplies, freight on ores to smelters and copper bullion to refineries, now therefore be it

Resolved, that this Congress notify the carriers serving the mining industries of this State that before it will be possible for the mining companies to resume operations it is imperative that the cost of transportation be materially modified.

Kingman.—No. 3 shaft of the United Eastern Mining Co. has reached a depth of 674 ft. The shaft is to be carried to the 800-ft. level, from which point cross-cutting and drifting on the vein will be done. The new tram to the mill from the Big Jim workings is almost complete. August production of the company was 8400 tons having a value of \$169,122, yielding a profit per ton of \$12.25.—A winze is now being sunk to the 1000-ft. level in the orebody recently found in the Oatman United mine. The vein was discovered on the 600-ft. level by diamond-drill work; it is now being opened by drifting. At this level the ore shows a width of 30 in. with gold content as high as \$105 per ton. A contract has been let for 3000 ft. of diamond-drilling.

The United American Mining Co., whose property is at Oatman, has made application to the Corporation Commission for a permit to sell 223,925 shares of stock at 20c. per share. Heretofore most of the stock has been purchased by local people. The main shaft of the mine has been sunk to the 700-ft. level, where some development work was done. There is ample machinery to carry on further work. A winze is now being sunk on the body of ore found in the Aztec vein, which has been opened on the 400-ft. and 600-ft. levels.

Ray.—Foreclosure proceedings against the Arizona Hercules Copper Co. have been started by the Empire Trust Co. of New York in the Superior Court of Pinal county. The suit is brought to foreclose a trust-deed given by the defendant company to the plaintiff to secure the issue of bonds in the aggregate of \$3,000,000. The mortgaged property includes mining claims situated in the Mineral Creek district, together with all water-power, water-rights, mill-sites, railroad, switches, rights-of-way, and other property. The action is brought on behalf of the holders of the \$3,000,000 worth of bonds, which were issued in January 1919. The bonds were to bear 7% interest, payable semi-annually, but at every interest period, it is alleged, the defendants defaulted and there is now due principal and interest. The mines of the company adjoin the Ray Consolidated Copper Co.'s property. The company also owns a mill at Belgravia near Kelvin.

CALIFORNIA

Alturas.—The Goose Lake Gold Mining Co. has found cinnabar ore. The deposit is said to average 3% mercury.

Darwin.—The Darwin Silver Co. has applied to the Federal Power Commission for a license to construct a transmission-line from the main high-tension line, owned by the city of Los Angeles, to its mines.

Forest.—The new Kate Hardy mill is now in operation. High-grade ore from the upper levels is being stamped. A new adit will be driven to cut the ore-shoot at greater depth.

Georgetown.—Litzenburg & McAllister have received two truckloads of machinery at the mine that they are opening on Travis creek three miles south of here.—R. G. Dougherty and Frank Drew have erected a 30-ton mill at the mine that they have leased on Slate mountain. Former lessees took out \$30,000 a few years ago.

Grass Valley.—It is reported on good authority that the interests that control the Metals Exploration Co., owners of the Idaho-Maryland mine, are behind the project to develop water-power in Plumas, Sierra, and Nevada counties. The Yuba Development Co., directed by Bulkeley Wells and Harry Payne Whitney, of New York, will advance \$25,000,000 for the construction and equipment of six power-plants, the principal ones being at Nelson Point, Crooked Bar, and Bean Creek. It is estimated that 200,000 hp. will be generated.

Jackson.—The monthly meeting of the Mother Lode mine superintendents was held on September 22 at the Argonaut mine. An inspection of the underground workings formed part of the program.

Natoma.—The California Dredge Operators Association met here on September 27 as guests of the Natomas Company of California, for which L. D. Hopfield is manager. Thirty-two members and a number of guests from the San Francisco section of the American Institute of Mining Engineers were present. The program for the field meeting during the day started with a visit to the Fair Oaks rock-plant. This plant has a capacity of 3000 tons of sized rock that is used for road material and for concrete aggregate. The old dredge-tailings that supply the material are excavated with steam-shovels. After a luncheon at the Citrus hotel, three of the dredges of the Natomas company were visited. No. 9 dredge, built with a wood hull in 1911, was sunk a few months ago. The pond has been pumped out and the dredge dismantled. The machinery is being moved by means of caterpillar tractors and trailers and by means of motor-trucks to a site near-by, where a new steel dredge will be erected. At the meeting in the evening the question of sampling dredge-ground was discussed. Chas. W. Gardner read a paper, in which he showed that the actual recovery in dredging frequently was as low as 50% and as high as 150% of the 'expectations' as indicated by sampling with

churn-drills. He emphasized the fact that prospect-drilling could not be done accurately and that the judgment of the engineer in interpreting results was the most important factor. R. G. Smith, engineer for the Natomas company, discussed the sundry sources of loss in dredging. Sampling of dredge-tailing is a difficult procedure, but his company is making a study of the various sources of loss that may account for the discrepancies between the expected and the realized recoveries.

Placerville. Joseph Morovitz is developing the Fairchild gravel mine. He has found a pay-shoot but has not yet determined the extent of it.

COLORADO

Breckenridge. Farncomb hill, famed for its wire-gold discoveries, but long neglected, is again the scene of activity. The Pontoon and Gladstone lodes, at the head of American gulch, the Key West and Fountain, the last named owned by the Camplon estate, are all being operated under lease.

Central City.—The modern electrically driven plant at the Frontenac is to be duplicated at the Adubbell shaft by the Eastern syndicate that recently took over the Frontenac properties. The Adubbell will be connected with the Lowe raise from the Newhouse tunnel, thereby affording both ventilation and drainage of the mine workings. The Midwest Mining Co. reports progress with the adit to drain the Cyclops workings to a depth of 400 ft. The company is mining a good grade of ore in the Alaska and Peru. The Alaska, two miles distant from the Cyclops, is producing silver-lead ore sampling 75 oz. silver and 10% lead. The ore is treated at the Iron City mill at Blackhawk, controlled by the company.

Cripple Creek. The Cresson continues heavy production. Thirteen cars were loaded out Monday and the minimum daily billing of the week has been nine cars. The Ajax Mines Leasing Co. is now shipping steadily to the Independence mill of the Portland company, near Victor. George M. Taylor, for the past 20 years general manager for the Portland Gold Mining Co., has resigned and Tom Crowe, superintendent, is in temporary charge.

Idaho Springs.—The Golden Edge property on Seaton mountain is again active; new equipment has been installed at the shaft and development on an extensive scale is planned. New track has been laid in the Empress tunnel of the Empire Consolidated company at North Empire preparatory to extending the tunnel. The Nelson brothers mill on Silver mountain is operating steadily; the plant is making a good grade of concentrate.

Montezuma.—The St. Johns property controlled by a British syndicate that ceased operating during the War has been leased to local and Denver men. The property was one of the early producers of Summit county. The Pennsylvania operated by the Liberty Mining & Reduction Co. is producing steadily and the mill is turning out around 20 tons of high-grade concentrate daily.

Silver Plume. Properties of the Chasfield M. & M. Co., operated under lease by the Silver Gem Mining Co., through the Gold Belt tunnel, are producing a good grade of both smelting and milling ore. On the Sea Gull vein a streak 6 to 8 in. wide is sampling \$250 per ton.

IDAHO

Coeur d'Alene.—A second furnace is to be blown-in at the Bunker Hill & Sullivan smelter. The increase in capacity is made possible by a recent accumulation of ore from the mines of the Coeur d'Alene region and the favorable freight-rates from British Columbian points, recently established. The Bunker Hill & Sullivan mine will be in a position to contribute more ore to the smelter through developments in progress on a new level 1400 ft. below the Kellogg tunnel.

Production from the mine is now 1200 tons per day. The new East mill, nearing completion, will have a daily capacity of 5000 tons. The Bunker Hill company shipped 100,000 oz. of silver to the United States Mint at San Francisco and \$11,000 in gold to the United States Assay-Office.

An option on the stock of the Hill Mining Co., in Slaughter House gulch, adjoining the East Caledonia on the east, has been secured by Patrick Brady and W. J. Stratton. A vein 4 ft. wide, containing 4% lead and 6 oz. silver per ton, has been intersected by a cross-cut at a depth of 200 ft. The vein will be followed and negotiations will be opened with the East Caledonia for permission to explore the Hill ground from the 400-ft. level of the East Caledonia.—Lessees operating on the property of the Western Union Mining Co. shipped ore having a gross value of \$54,445 between November 19, 1920, and August 18, 1921. The net smelter returns were \$35,725 and the royalty to the company was \$8932. Four sets of lessees are now at work.—The Columbus Mining Co. has received a new compressor, which will be installed on its property on Eagle creek. The plant will be ready for operation by October 25.

The Ajax Mining Co. will drive a new tunnel near Burke, according to A. C. Bixby, manager. A compressor and other machinery is being removed from the Moonlight tunnel. The tunnel to be driven will attain an additional depth of 500 ft. below the workings in which ore was disclosed.—J. W. Buchler, manager for the Silver Reef Mining Co., reports that the company will soon commence development through the lower tunnel of the Homestake mine. The Silver Reef has secured an easement to use this tunnel. By extending the tunnel about 900 ft. an additional depth of 1100 ft. will be secured, gaining a total depth of 1700 ft. below the surface. In the present tunnel, Buchler reports a shoot 887 ft. long, sometimes 12 ft. wide, with high-grade ore on one wall.

Fairfield.—The concentrating plant of the Walton Mines Co., which is operating a property in the Smokey district, is reported to be nearly ready to begin operations. The plant will have a capacity of 50 tons daily. The ore to be treated, of which there is said to be 10,000 tons, with a value of \$18 per ton, is a silver-lead sulphide with a high gold content. Mining costs in this particular property, it is said, will be low due to the manner in which the ore has been opened up and to the fact that but little snow is expected.

MICHIGAN

Houghton.—Quincy should be one of the first of the Lake mines to revive when normal conditions in the metal market return. Not only is development at depth in all shafts satisfactory, but improvements at mine, mill, and smelter have effected notable economies. The new hoisting arrangement at No. 2 and 8 shafts, the installation of re-grinding units in the stamp-mill, and the completion of the new furnace and automatic handling devices at the smelter will contribute largely to a lowering of costs when normal operations are resumed. The re-grinding installation alone was responsible last year for the recovery of nearly 2,500,000 lb. of refined copper. Quincy is fortunate, too, in having its own railroad and is not subject to the high haulage charges paid by some of the other mines of the district. No change in Quincy's present policy is contemplated, despite rumors to the contrary. Although failing to 'break even' at the present price of copper, Quincy is holding an organization together and will continue to operate on a 50% basis throughout the winter.

Mohawk continues to work to the capacity of its stamp-mill. A full program of mining and development is under way throughout the mine, with little or no change from day to day in output of 'rock' or yield of copper per ton. Daily 'rock' shipments average about 2600 tons, while the yield is approximately 23 lb. of refined copper to the ton. Mohawk is now sinking, drifting, and stoping in No. 1 shaft and some

particularly good ground is being opened north of the shaft.

Copper Range 'rock' is a free-milling amygdaloid, susceptible to fine grinding. The loss per ton is about 5 lb., but this can be reduced another pound by re-grinding. Copper Range is convinced that the solution of its problem is finer grinding rather than leaching or flotation. Even if flotation could be successfully applied it is believed it would be too expensive to undertake because of the relatively small metal content of the sand and the large outlay that would be required for equipment and handling.

All but one of the stamp-head units in the Quincy mill have been supplied with complete re-grinding equipment. As a result, Quincy last year recovered nearly two and a half million pounds of copper that otherwise would have been lost.

NEVADA

Arrowhead.—The Arrowhead company has been re-financed in New York and San Francisco, according to reports, and the shaft is to be sunk to 600 ft. immediately with the money obtained. The shaft is now 330 ft. deep. It is planned to build a mill if the ore-shoots are found to continue to 600 feet.

Cuprite.—The Super-Silica Corporation, formed nearly a year ago to mine and mill silica near Cuprite, has been re-financed and work is to be resumed. The main trouble in the first attempt of the company was lack of adequate power and milling facilities, but this has been remedied by the purchase of a 50-hp. oil-burning engine and a 6 by 22 Hardinge silex-lined pebble-mill. The mill is expected to produce one ton per hour of 400-mesh material, which will mean a good output of 'air-float' in addition to that drawn off the crusher and screens. The plant will be in charge of Ernest C. Wood.

Divide.—The Tonopah Divide is earning \$5000 to \$10,000 monthly, according to H. C. Brougher, president of the company, who says that after water has been developed a mill will be built. Mr. Brougher said that the ore now exposed in the mine and that on the dumps was ample to justify the erection of a mill and that custom ore could be expected from other mines in the district. He said development work is opening ore considerably in excess of that being shipped. It is said that orebodies have been opened in several parts of the mine that have made a great increase in the ore-reserves.—The Divide Extension is shipping \$50 ore to the MacNamara mill in Tonopah at a rate of 900 tons monthly. The ore is coming from stopes above the 200-ft. level.—The Gold Zone continues cross-cutting on the 900-ft. level to open the vein found on the 500 and 700.—The Brougher, south of the shaft on the 500-ft. level, is drifting on a 1-ft. width of \$75 to \$80 ore, and it is thought by Gust Hanson, superintendent, that the Divide Extension vein has been found on the 185-ft. level.

Ely.—The shipment of 10,000 tons of blister-copper from the stock stored at the McGill smelter has been announced by C. B. Lakenan, general manager for the Nevada Consolidated Copper Co. The copper will be shipped over the Western Pacific railway in 20-car trains to San Francisco, thence by steamer through the Panama canal to Baltimore. While this is only part of the copper on hand at the smelter, the movement is accepted as an indication that the surplus is being reduced rapidly.

Eureka.—The Bullwhacker, developing through the shaft of the adjoining Eureka-Holly, has driven on the 430-ft. level to a point under the Laird orebody, opened on the 330-ft. level, and has started a raise.—The Eureka-Holly is mining a small tonnage of high-grade ore from two stopes on the 400-ft. level and is driving on the 600 north for the fault beyond which ore was exposed on levels above.—The Uncle Sam tunnel is being advanced and high-grade mill-ore is being broken.

Gardnerville.—On the Veta Grande property, near here, the winze from the lower tunnel has entered the vein, the dip of which changes just below the tunnel level from about 45° to 80°. A working shaft has been started south of the tunnel portal. The vein is, as the name implies, of great size. High-grade ore is exposed for considerable distances in drifts, raises, and winzes driven by later owners. E. J. Roberts is the engineer-manager and San Francisco men control the enterprise, a close corporation.

Leadville.—The main drift on the 300-ft. level of the Leadville mine has broken pay-ore for a distance of 600 ft. The ore is a silver-lead sulphide, containing masses of rich galena that is sacked and shipped to smelters. The ore is treated in the company's 35-ton flotation mill. It passes from the Blake crusher through a Marcy ball-mill and a Dorr thickener, to K & K flotation machines. The concentrate goes to a Dorr thickener and Oliver filter, leaving 8% moisture. Shipments average six tons of concentrate daily, assaying from \$200 to \$240 per ton. The mill has been treating 30 tons and the new water-line will increase capacity to 35 tons. Extraction of silver is 91.5% and of lead 92%. Power for the mill and mining plant is supplied by two Fairbanks-Morse semi-Diesel engines of 75 and 100 hp. A direct-current generator drives the motors and a 275-cu. ft. Ingersoll-Rand compressor. Homer O'Connell is superintendent.

Log Springs.—A steam-shovel, and pipe, cement, and lumber in earload lots are being hauled from Stonewall Siding, on the Tonopah & Tidewater railroad, to Log Springs for use by Los Angeles interests in placer mining on the Benton-McLaughlin ground, at Log Springs, 45 miles south of Goldfield. A dam has been built for the storage of water, a camp has been built, and it is evident that the placer is to be worked on a good scale.

Pioneer.—The Pioneer will soon start driving north-west from the 800-ft., or bottom, level of the shaft, to cut the vein under the old bonanza stopes that extent from the 200-ft. level to the surface.

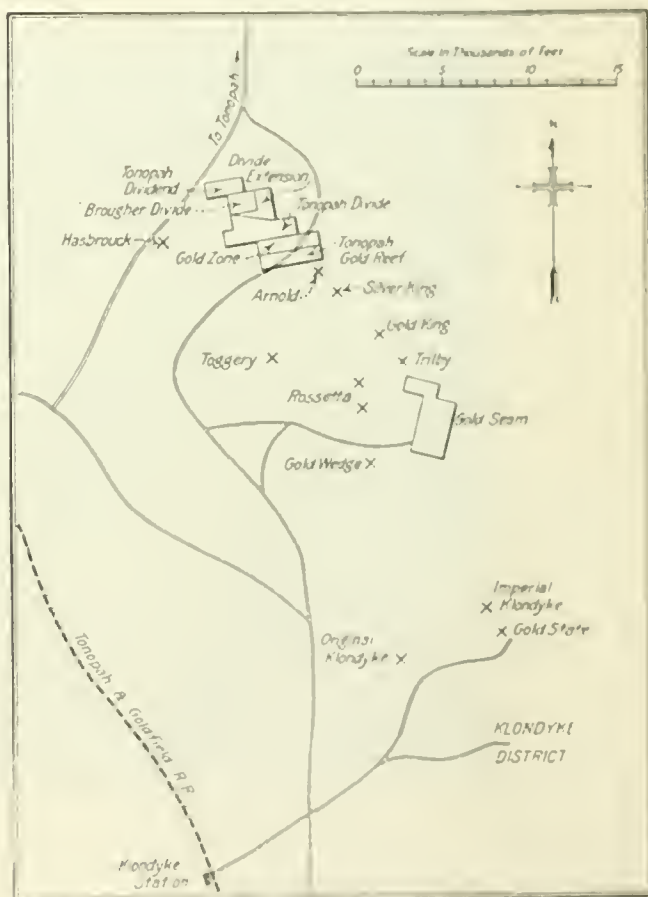

Reno.—H. Foster Bain, director of the Bureau of Mines, and Marlon E. Rhodes, Congressman from Missouri, and chairman of the House Committee on Mines and Mining, addressed a large gathering of mining men, engineers, and attorneys at the Chamber of Commerce while visiting here. Mr. Bain explained the position of the Bureau in connection with the proposed mining bill, now before Congress, advocating its passage. Mr. Rhodes said his committee would not act on the measure before the first of next year. Several members of the audience spoke in opposition to the bill. The only provision in the new mining bill that seems to have any support from Nevada mining men is that repealing the so-called apex law, and many oppose any change whatever. Those advocating the retention of the apex law hold that abuses under this law have been costly only to the large corporations and that proper enforcement of existing laws would provide ample protection to mine-owners, both large and small. Other provisions of the bill have aroused a storm of protest.

Silver Peak.—The mill of the Silver Peak Chemical Co. is finally to be put in operation, according to reports, after several trial runs that were partly successful. It is said that the company has been financed on a scale that will ensure success and that the mill has been perfected. The plant is to produce alum and sulphur from what is said to be the only deposit of water-soluble potash alum known. The deposit, containing an average of 20 to 25% pure potash alum, is practically without limit.

Virginia City.—Surface sampling on the 'middle-mines' group, directed by Albert Burch, has been completed; work is being continued in the Hale & Norcross tunnel, the face of which is within 100 ft. of the hanging wall of the Com-

stock lode. The Hale & Norcross, Chollar-Potosi, Gould & Curry, and Best & Belcher will be sampled by re-opening old upper-level workings, and this work will occupy at least two months. More than 1400 samples were taken from surface workings and dumps. The haulage tunnel of the United Comstock Mines Co. has connected from the portal with the Knickerbocker shaft at a depth of 110 ft. The only remaining stretch is that between the Knickerbocker and Belcher shafts, about 1800 ft. Four shovels are driving both headings, making 18 ft. per day. The tunnel, nearly 10,000 ft. long, will be completed by January 1. The Pittsburg Comstock Co. is opening the old lower tunnel in which good ore is exposed and is laying track. The heading will be continued to cut the Bright Star vein at its intersection with a cross-fracture that has produced high-grade ore from the upper tunnel.

Winnemucca.—The shaft of the Nevada Harmony is re-

Map of Divide District

ported to be in 5 ft. of \$75 silver-gold ore at a depth of 200 ft. The shaft has been in ore from the surface and in this and other workings there is said to be \$100,000 worth of ore exposed. Sinking was resumed recently at 180 ft. and it will be continued until the 300-ft. point has been reached. George D. Williams is general manager.

OREGON

Gold Hill.—In spite of the low price of quicksilver, orebodies in several quicksilver mines in this district are being developed. No furnaces are being operated, however. The War Eagle company, with headquarters at Medford, the largest quicksilver mine in this district, has a crew opening a large body of cinnabar ore, while it is also preparing to spend \$15,000 in building a new water-system to supply its plant. Heretofore the mine has furnished the water to operate the mill and furnaces. The War

Eagle mine is equipped with a 25-ton Scott furnace and two 12-pipe retorts for auxiliary purposes.

The Millionaire gold mine, three miles south of here, which was re-opened last season, is operating its mill steadily on a large body of rich ore which was stored for milling some years ago. Ore from a large body in the new works is also being reduced. The main shaft on the mine has been abandoned for the present and the shaft-house and equipment has been re-built a few hundred feet east on the vein. The new shaft has been driven to a depth of 200 ft., and drifting both ways on the vein is under way, but principally toward the old shaft which has a depth of 450 ft. On the completion of the new level connection will be made and the old works will be unwatered and mined.

UTAH

Alta.—Operation of the Little Cottonwood Transportation Co.'s railroad, which hauls ore from local mines to the valley smelters, was suspended for the season on September 24. The company will continue to operate its stage line as long as the weather permits.—Development work in No. 3 raise at the Alta Tunnel property continues to give encouraging results. Recent assays of a 4-ft. strike give gross returns of \$70 to \$80 per ton, or \$55 to \$65, after deducting transportation and smelting charges.

Beaver.—Wilford Robinson and James E. Robinson have taken a lease on the old Sheep Rock mines, and will resume operations immediately. It is reported that a vein of mill-ore has been opened that assays about \$6 per ton of gold; a second vein gives returns of about \$10.40 per ton in gold.

Bingham.—The United States Smelting Co. is developing its mines at greater depth. A shaft has been sunk 200 ft. below the Niagara Tunnel level, which, at present, is the deepest level in the mine and the main haulage-tunnel. D. D. Muir, mine manager, reports that the exploratory work is opening new bodies of good-grade ore. The mine is now producing about 450 tons of ore per day; about 300 men are employed.

Between 500 and 600 men are now employed in Bingham mines, whereas during the War about 4000 employees were on the payrolls. The United States Smelting Co.'s mines employ about 300 men; Utah Copper, 70; Montana-Bingham, 70; Utah Metal & Tunnel, 15; Utah-Apex, 12; Utah Consolidated, 12; Bingham Mines, 10; Bingham-Galena, 10; Bingham-Tooele, 6; and lessees, about 50.

Eureka.—The controversy for the control of the Lehi-Tintic Mining Co. has reached the courts. On September 26, Elias Hansen, judge of the Fourth District Court at Provo, issued an order restraining the Nicholes faction from interfering with the operation of the mine, and ordering Nicholes and his associates to surrender possession of the property. On September 12, Nicholes and his friends attempted to hold a stockholders' meeting and elect their own officers, after which they went to the mine and took possession. Later in the day, the 'official' stockholders' meeting was held, at which Charles Zabriskie, who has been president of the company for the past two years, was re-elected.

Ore shipments for the week ending September 24 totaled 144 cars, as against 161 carloads for the previous week. The Tintic Standard shipped 38 cars; Chief Consolidated, 36; Victoria, 13; Eagle & Blue Bell, 11; Dragon, 8; Iron King, 5; Iron Blossom, 7; Swansea, 5; Bullion-Beck, 3; Centennial-Eureka, 3; Gemini, 3; Mammoth, 2; Eureka Hills, 2; Colorado, 2; Silver Park 2; and Sunbeam, 1.

It is reported that the United States Smelting Co. will undertake a program of development in the East Tintic section. While officials of the company are non-committal, it is said that an option has been taken on the old Addle property. The tunnels and shafts are being cleaned out. This property is situated north of the Eureka-Bullion hold-

ings and in close proximity to the Tintic Standard and Chief Consolidated mines.

Moab.—Lawrence Peachman reports that an excellent showing of gold and copper ore has been uncovered in the Copper Queen property, in the Blue mountains, south of here. Development has been in progress during the past three months, and a shaft sunk to a depth of 70 ft., where a vein was cut. On the hanging-wall side, from 3 to 4 ft. of milling ore is exposed, while on the foot-wall side, ore of smelting grade was found.

H. M. Armstrong, manager for the Keystone Metals Co., operating mining properties near the Utah-Colorado line, announces that a new road, 11 miles long, has been completed, which will make a saving of 20 miles in traveling between Grand Junction and Polar Mesa, where the company's uranium mines are situated.

Park City.—Richard Pelton, superintendent of the Ontario mine, states that 87 lessees are now at work on all levels between the 900 and 1800-ft., all of whom are making better than regular wages. Work is being carried on by the company on the 2000-ft. level.

Shipments of ore for the week ending September 24 totaled 1436 tons, of which the Judge companies shipped 593; Silver King Coalition, 560; and Ontario, 283. Shipments the previous week were 1946 tons.

Conditions are reported as favorable at the New Quincy property. A winze sunk from the J. C. R. drift, from the Little Bell shaft, is now at a vertical depth of about 950 ft. below the surface. The winze has cut from 2½ to 3 ft. of high-grade ore.

Salt Lake City.—The annual dinner of the Utah Chapter of the American Institute of Mining and Metallurgical Engineers was held on September 28. There was a large attendance. The main speaker of the evening was H. Foster Bain, director of the United States Bureau of Mines. Senator Key Pittman of Nevada was also among the speakers. John D. Gray, mining attorney, of the Coeur d'Alene district, acted as toastmaster. While in Utah, Mr. Bain and the members of his party were taken to Bingham to visit the Utah Copper mine. L. S. Cates, assistant general manager, accompanied the party on the trip.

BRITISH COLUMBIA

Alice Arm.—The Homestake group, under bond to the Consolidated Homestake Mining & Development Co., of Vancouver, is being opened by three tunnels. A site has been prepared for a compressor plant, which machinery, together with other equipment, will be shipped in as soon as the snow disappears. Water-power from a creek on the company's property will supply energy.

Anyox.—A vote taken recently by the miners and smeltermen at Anyox as to whether they should accept a further wage-reduction rather than have the Granby company close its plant was strongly in favor of a wage-reduction. The following is the new schedule: first-class metal-craftsmen and carpenters, \$4.75; painters, \$4.25; miners, \$4; shovelers, \$3.70; teamsters, \$3.55; and outside laborers, \$3.15. The company has made a reduction of 25% on the rent of all its houses and reduced the board at its mess-room to \$1 per day.

Prince Rupert.—John Wilman, manager for the Kleanza Mountain Copper Co., which has been developing a property near Usk for the past four years, is authority for the statement that the company will erect a modern mill and concentrating plant in the spring, the small Gibson mill now on the property is inadequate to treat the large body of ore that has been developed. According to Wilman, there has been a considerable amount of prospecting within 25 miles of Usk during the past summer, and some promising gold-

copper prospects have been sufficiently developed to allow of examinations.

Princeton.—The Kettle Valley Railway Co. is repairing the branch from here to Copper Mountain. Though no announcement has been made that the Canada Copper Corporation's mine and mill are to be re-started, it can be only with this end in view that the railway is being repaired. It is hardly likely, however, that the plants will be re-started before spring, and it is uncertain under whose auspices they will be operated.

Stewart.—The driving of two cross-cuts on the property of the Bush Mines, Ltd., has served to open a large body of ore. This work was done from No. 1 and No. 2 tunnels and the results have proved the soundness of the reasoning of those in charge.—The Lucky Boy group, on Fish creek, the property of Behnson Brothers, of Victoria, shows promising development.

property. It admits that its free miner's license expired on May 31, 1917, but alleges it was not aware of this until 1918. It charges Alexander with making false affidavits when applying for title and alleges that he in order to acquire the company's stamp mill and other machinery, arranged that judgment be obtained against the company in the county court, at Atlin. The company's mill, buildings, and machinery were valued at \$20,000 and were sold under process of execution to realize a judgment of \$402. The property was bought in by Alexander, who, it is alleged, prevented competitive bidding at the sale by threat. The plaintiff company asks for a declaration that it is the owner of the mine and that Alexander and his associates fraudulently, deceitfully, and unlawfully obtained the Crown grants.

MEXICO

Chihuahua.—Antonio Wilson and associates have filed ap-

Hydraulicking at Ten Mile, Trout Lake District, B. C.

Vancouver.—Litigation has commenced in the British Columbian courts at Vancouver, the issue of which is ownership of the Engineer mine in the Atlin district. This is admittedly one of the richest lode gold properties of the Province; \$1,000,000 has been offered for it on more than one occasion. Action is being brought by the Engineer Mining Co. against J. A. Fraser as administrator of the estate of the late Capt. James Alexander, and others. The history of the mine dates back to 1899, when the claims were located by two Swedes, Charles A. Anderson and Frank Nelson, representing the Aga Gold Mining Partnership. These afterward were taken over by the Engineering Mining Co., an Alaskan company with headquarters at Skagway. Crown grants subsequently were applied for but were refused by the Gold Commissioner and Mining Recorder, doubtless on the ground that the provisions of the law had not been fully complied with. Meanwhile, it is alleged by the plaintiff that Alexander and his partners jumped his claim, re-staked, and eventually obtained Crown grants. The company asserts that it expended \$40,000 on development of the

property before the mining agent at Camargo for the titles to La Fortuna, a group of gold, silver, lead, and copper mines situated in the Morales mountains at San Francisco de Conchos. Two new denunciations have been filed for record with the Chihuahua agency, one by Jacob W. Breach, who has located 10 claims embracing the old abandoned Fernandez Leal mine on the Guaslsaco ranch, and the other filing is made by W. D. Howe, who has located the Santo Domingo de la Calzada group of gold-silver properties, consisting of five contiguous claims, adjoining La Reforma and La Prieta mines.

Concepcion del Oro.—Silvestre Gonzales, well-known mining man of the Concepcion del Oro district, has recently located a number of new claims containing strong veins of gold, silver, and copper ores. There are two groups, one of two claims to be titled under the name of San Ignacio, and the other, comprising eight contiguous claims, to be patented under the name of Santa Fe. The Santa Fe group is situated near El Favor and La Linda mines in the Temeroso mountains.

Durango.—Gerald E. Norton, who has extensive mining interests in this State, has added 15 new claims to his holdings. The survey will include the old Prolongacion, La Boera, Rosa Maria, and Guadalupe mines, which have been declared forfeited for non-payment of mining taxes. The properties are situated in the San Patricio mining camp in the municipality of Pueblo Nuevo. They are to be titled under one name, La Cubierta.—Jesus Alzpueros, representing Francisco Velez, has applied for titles to El Raton group of ten claims in the Bufa de Inde mining camp, about five miles south of Inde. The new location is surrounded by a number of producing mines such as La Torre, La Natividad, La Fe, and La Mariposa.

El Oro.—An explosion and fire in the interior of the San Juan mines has caused the suspension of operations. One miner by the name of Juan Martinez died from the effects of gas and other miners were entombed within the lower workings. Experts are conducting an investigation of the disaster to ascertain its origin.

Santa Rita.—The Aristeo and La Tajitos mines, which were recently forfeited for non-payment of taxes, have been re-located by Jesus Robledo, who is having the old workings cleaned out. He will sink some of the shafts to a greater depth. The properties are adjacent to the Recompensa and La Purisima mines.

Zacatecas.—Benjamin Cristerna has located the Paloma de Oro group of mines adjoining the Numero 5 and El Bote mines near this city. He is developing a vein of gold ore.—La Hija del Trabajo, a group of four claims, has been located by Salvador Zajur. The property is situated along the Enciso Arroyo a short distance west of this city. The ores from this new location are similar to those extracted from the Campana de Oro mines, which are situated in the same region.

ONTARIO

Cobalt.—The annual meeting of the Temiskaming was held on September 22, when J. P. Bickell, president, informed the shareholders that the entire future of the company depended on the success of the Blue Diamond coal mine in which the company has a half-interest. The old mine could not be operated at a profit unless silver rose above 70c. per ounce and remained there.

The shareholders of the Oxford Cobalt on September 19 ratified the agreement for the purchase of the Waldman claim and two other locations giving the company a total area of 100 acres. The installation of the new plant using electric power has been completed and sinking resumed.

The liquidation in connection with the Bailey Cobalt Mines, which has lasted for seven years, was brought to a close on September 23 when the shareholders authorized the directors to make application to terminate proceedings. In accordance with the settlement effected the Bailey Cobalt is now a holding company with an interest in the Bailey Silver Mines, Ltd., which has taken over the assets of the Bailey Cobalt and the Bailey Silver Customs mill. The company has completed a standard-gauge railway siding from the Nipissing Central Railway to its mine, and can now ship ore direct from its mine to the mill.

Porcupine.—At the annual meeting of the McIntyre-Porcupine on September 22, J. P. Bickell, president, stated that fears were entertained of a power shortage as the streams had been dried up to an unusual degree by the excessive heat of the summer. Arrangements had been made for the installation of an auxiliary steam-plant later in the year should it appear necessary. He explained that the Blue Diamond coal mine of Alberta, of which the McIntyre and Temiskaming companies are joint owners, had been operating at a profit during the last two months. R. J. Ennis, general manager, stated that the present estimated value of ore-reserves down to the 1500-ft. level was \$6,292,600.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. H. Goodchild is at Kirkland Lake, in Ontario.

E. J. Collins, of Duluth, Minnesota, was here last week.

Henry Hanson is in San Francisco from Keeler, California.

F. J. Nagel, of Denver, is at Guadalajara, Jalisco, Mexico.

Arthur I. Davis, of Toronto, Canada, was in San Francisco last week.

Henry Krumb is at Los Angeles, where he will remain for some time.

Charles F. Williams, of Mansfield, Ohio, is now at Keno Hill, in the Yukon.

R. L. Chase is examining properties near Ouray and Silverton, Colorado.

Lewis Bradbury has returned to Los Angeles. He will be going to Mexico shortly.

E. A. Mandertfield, of Houghton, Michigan, is at Santa Eulalia, Chihuahua, Mexico.

Walter Fitch, president of the Chief Con. Mining Co., at Eureka, Utah, is in southern California.

C. T. Hutchinson, business manager for the 'M. & S. P.', leaves for Chicago and New York on October 7.

W. D. McMillan left San Francisco on October 4, to return to the Kasin diamond-fields in the Belgian Congo.

Daniel Guggenheim, formerly president of the American Smelting & Refining Co., has returned to New York from Europe.

Samuel W. Cohen has returned to Montreal after an examination of the Murray claims at Elbow Lake, in northern Manitoba.

C. A. Week, of Oakland, has completed a preliminary examination of the placer mines of the lower Trinity river, near Salyer, California.

Robert N. Bell, formerly State Metal Mine Inspector of Idaho, and now a consulting mining engineer at Boise, spent several days at Salt Lake City recently.

S. Paul Lindan has become engineer for the Western branch of the United States Gypsum Co., with offices in the Citizen's National Bank Bldg., Los Angeles.

T. A. Rickard has been invited to deliver the principal address on the occasion of the 50th anniversary of the Missouri School of Mines, at Rolla, on November 5.

G. W. Gray has resigned as assistant manager and chief mining engineer to the Rio Tinto mines in Spain, and has entered into partnership with W. Selkirk, consulting mining engineer, London.

Harry Sordy, who has been with the Gold' Mint Mining Co., at Wasilla, Alaska, sailed on the 'Northwester' from Seward for Seattle. He will be superintendent for the Alameda Mines Co., at Merlin, Oregon.

Henry J. Kimman, since 1902 manager of the Cleveland, Ohio, plant of the Chicago Pneumatic Tool Co., died at Cleveland on September 7. He was born in Holland in 1863, and emigrated to America with his parents who settled at Chicago in 1870. Being of a mechanical turn of mind he designed and in collaboration with his brother, T. P. Kimman, built one of the first practical portable piston air-drills, known as the Little Giant. Soon after engaging in the manufacture of air-drills he became associated with E. N. Hurley and they formed the Standard Pneumatic Tool Co. in 1898. He became associated with the Chicago Pneumatic Tool Co. in the consolidation made in 1901, at which time he became manager of the Cleveland plant of the company, in which capacity he remained until his death.

THE METAL MARKET

METAL PRICES

San Francisco, September 27

Aluminum-dust, cents per pound.....	65
Aluminum, sheet, cents per pound.....	72
Antimony, cents per pound.....	6
Copper, electrolytic, cents per pound.....	12.25-12.50
Lead, pig, cents per pound.....	4.95-5.95
Platinum, pure, per ounce.....	\$78
Platinum, 10% Iridium, per ounce.....	\$96
Zinc, slab, cents per pound.....	6
Zinc-dust, cents per pound.....	9

EASTERN METAL MARKET

(By wire from New York)

October 4 —Copper is active and strong. Lead is quiet but firm. Zinc is more active and higher.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

Eastern Metal Market

New York, September 28.

A distinctly cheerful tone permeates all the markets. Prices in most of them have advanced and all are firm to steady.

Copper buying has increased; but while prices are thus far firm, they are not higher.

Steady buying of Straits tin continues with prices firm to higher.

Another advance is recorded in lead, with the good demand sustained.

The zinc market is decidedly more active and higher.

Antimony has also advanced.

IRON AND STEEL

Leaders in the steel trade speak of larger mill-operations in the last quarter of the year with a confidence they did not show as September opened. The past week has brought further signs of betterment, says 'The Iron Age'. As in wire products two weeks previous, the advance for sheets brought a flood of orders and specifications at the old prices, estimated at close to 200,000 tons. Sheet manufacturers are running at 70 to 75% of capacity under the replenished demand developed by the new turn in the market. There is pretty general adherence to the new prices on black and galvanized sheets. Along with this advance has come an effort to lift the sheet-bar market. Two or three independent mills ask \$32, or \$2 above the present contract basis. Not a little stir was created by the action of the Carnegie Steel Co., which became known on Monday, putting its prices on plates and structural shapes at 1.75c. and on bars at 1.65c.

The increased rate of wire, sheet, and tin-plate production is encouraging, but these light products make a smaller increase in the output of ingots than might be gathered from some optimistic reviews of the week.

The pig-iron market shows a decided increase in buying. One manufacturing company has purchased 15,000 tons of foundry iron for last-quarter delivery, 5000 tons for each of its three plants.

COPPER

The better feeling which has permeated nearly all the markets recently has at last had a definite reflection in the copper market. Consumers have been waiting in the belief that the recent stiffness in values was unwarranted and that they could purchase at lower prices later. With the close of the month and no evidence of the weakness which has characterized the market in previous recent months, buyers have become more interested. This has resulted in larger inquiry and in the buying in the past week, by one large consumer, of 5,000,000 lb. of electrolytic copper. There have been other small sales, but this one is easily the feature and dwarfs anything in some time. It is reported that the same company is about to ask for another 2500 tons. There are also unconfirmed reports that at least 4000 tons in all was sold last week for domestic consumption. The large purchase referred to was made at prices ranging from 11.90c. to 12.37½c. delivered, and this has resulted in the cleaning up of all 12.25c. metal, it is believed, thus placing the market firmly on a 12.37½c. delivered, or 12.12½c., New York, basis. Some are quoting as high as 12.50c., delivered. Foreign demand, in view of exchange, is moderate, except perhaps to the Far East.

TIN

The market each day of the week covered by this report has been quiet to stagnant excepting on one day, Wednesday, September 21, when 300 to 400 tons of spot and future Straits tin was sold, nearly all to consumers. The prices

varied from 26.62½c. for spot to 26.87½c. for future. This steady buying of Straits tin has been a feature of each week's report for some time now and Straits tin easily dominates the market. Arrivals thus far this month have been 2560 tons with 3025 tons reported afloat.

LEAD

The market continues to rise, due again this week to an advance by the leading producer which last Friday raised its price from 4.65 to 4.70c., New York and St. Louis. Demand has been and is so good that it is stated that this producer is out of the market. With most independent sellers unwilling to sell as low as 4.70c., New York, the outside market is generally quoted at 4.75 to 4.80c., New York, or 4.45 to 4.50c., St. Louis. The market is strong and cheerful.

ZINC

A decided change has come over this market. Buying has increased and inquiries are more numerous. Prices have also advanced until prime Western for early delivery is difficult to buy as low as 4.35c., St. Louis, or 4.85c., New York. One reason is that producers are selling only their monthly production and not their stocks and at the end of the month have sold practically all metal available. Also output is estimated to be under 20% of capacity as it exists today. Prime Western for early or October delivery is quoted at 4.35 to 4.40c., St. Louis, or 4.85 to 4.90c., New York. There has also been a good demand for high-grade metal from galvanizers of wire, sales having been made at a fairly large spread over prime Western values, based on St. Louis prices.

ANTIMONY

The market is higher, due largely to advance in asking prices of holders of spot antimony. Wholesale lots for early delivery are quoted at 4.60c., New York, duty paid.

ALUMINUM

The leading interest has not changed its quotation for wholesale lots of virgin metal, 98 to 99% pure, which still stands at 24.50c., f.o.b. plant, but imported metal is a little lower at 18 to 20c., New York, duty paid.

ORES

Tungsten: The improvement in the steel trade has not yet been reflected in this market and prices continue nominally unchanged at \$3 per unit up, depending on the grade and the quantity.

Ferro-tungsten: There has been no change, the quotation for the domestic alloy being nominal at around 40 to 45c., while the foreign product is quoted at 50c. per pound of contained tungsten.

Molybdenum: There is no demand and prices are nominal at 50c. per pound of MoS₂ in regular concentrates.

Manganese: High-grade foreign ore is quoted at 20c. per unit, seaboard, with no demand reported. Imports in August are officially reported as 28,939 gross tons, making the total for the first eight months 326,342 tons, against 334,590 tons for the same eight months last year.

Manganese-Iron Alloys: Demand for ferro-manganese has quieted down and sales of only 300 tons are reported in the past week. Inquiries are confined to a few carload lots. Prices are unchanged at \$58.35, seaboard, for the British alloy, with American producers meeting this price, adding the freight to point of consumption. Imports of ferro-manganese in August were only 320 tons, or 5801 tons for the first 8 months as against 33,515 tons for the first 8 months in 1920. There is only a light demand for spiegel-eisen with prices unchanged at \$25 to \$26, furnace.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

ELECTRIC PUMPS UNDERGROUND

'Prescott-Menominee Mine-Pumps' is the title of an exceptionally handsome new catalogue just published by the Prescott Co., of Menominee, Michigan. The company specializes in electric pumps for deep mines, and the greater part of the new publication is devoted to a description of equipment designed for this purpose. Recent years have witnessed a remarkable development in pumping machinery for mines. There are two important reasons for this: the ever-increasing use and adaptation of electricity in mining operations, and the increasing depths to which mine-shafts are sunk. Electrically-driven holsts, compressors, and haulage-systems are being used more widely than ever and the same tendency is evident in the building of pumping

working pressure with a large factor of safety, their metal must be of ample thickness and properly apportioned to the various sections and parts. Mine-pump water ends are continually being subjected to shock-pressures which sometime even exceed the load. This danger becomes emphasized in electric pumps because of their positive and rigid power-action as compared with steam-driven pumps with their resiliancy and steam-cushion effect which tends to absorb or soften similar shock.

Of equal importance is their design with reference to the flow of water through them. Water passages and valve-areas must be not only large enough to keep friction losses down to a minimum, but so designed to keep the velocity uniform throughout the pump. This feature of low and uniform velocities is of vital importance, for it permits of

Prescott-Menominee Electric Pump Lifting 2400 Feet

machinery. Generally electric pumps can be operated more economically than steam; but, even if they could not, there is a convenience about them that is highly desirable. There are no long leaky steam-lines in the shafts with their attendant losses. Electric pumps are clean and easy to handle; the pump-rooms can be kept cool and comfortable instead of over-heated. The cost of pumping is receiving particular attention at this time and economy of operation is really more important than low first cost.

Prescott-Menominee pumps are designed and built by men who are familiar with underground conditions and who understand the requirements of severe and continuous service. None but the best can stand up under such conditions and it is to meet these conditions that Prescott-Menominee pumps are designed and built.

There are three governing factors in the type of water-end to be selected for mine pumping: the quantity of water to be handled, the character of the water, and the head, or pressure, against which it is to be pumped. Above all things, water-ends must be strong enough to stand their

the highest plunger-speeds without loss of power due to excessive friction and on it largely depends the economic performance of the entire unit.

Power-transmission to the water-ends in most of the Prescott-Menominee pumps is accomplished through a set of single-reduction double-helical gears of the herringbone type. The fundamental and conspicuous advantages of this kind of gearing are its greatly increased mechanical efficiency over all other forms and the high ratios of reduction possible between the gear and pinion. The entire power-end of Prescott pumps is heavy, strong, and absolutely solid and rigid; a condition which is of vital importance on motor-driven geared pumping-units. The reason for using herringbone gears on electric- and power-driven pumps is often asked, and why these gears are considered superior to the older forms of straight-tooth or spur gears. The reasons follow: The work of the pinion-gear is to so drive the other gear that it will revolve steadily and continuously; consequently there should be no intermittency in the tooth pressure at any time or in any part of the revolution. Spur-gears

do not fully answer this requirement, while herringbone gears do. The method by which a small spur-pinion drives a larger gear has been described as striking its teeth a succession of blows with a hammer. This may sound like an exaggerated statement, yet it describes precisely the action of a straight-toothed pinion, especially if it has but few teeth or becomes worn.

Herringbone gears are really double helical gears, with the helix (spiral angle) of teeth sufficiently steep to ensure an overlapping or screw-like contact between the adjacent teeth, thus compelling a uniform, even, and continuous shove or push in the direction of the load and throughout the entire revolution. It is clear, therefore, that this form of gear much more nearly approaches the ideal in the performance of the work desired.

The concluding pages of the booklet are devoted to some useful engineering tables and sundry general information for the pump user.

THE KROM SINTERING SYSTEM

The Krom sintering system successfully overcomes, it is said, the difficulty pertaining to the sintering of these ores, flue-dust, concentrates, etc., which are in a finely divided form, and which stick tenaciously to the sintering grate. The former condition requires special mechanical construction for securing a uniform sintering draught through the charge, and the latter condition requires means for economically removing the same from the grate. The Krom system of sintering is based on the unit-oven principle, so successfully developed by the modern by-product coke-ovens.

To produce either coke or sinter most satisfactorily the period of heat treatment must be under control independent of all other steps in the process, such as charging, igniting, and discharging. In both coking and sintering operations the treatment is perfectly controlled by unit charges, namely, separate ovens or pans independently charged and discharged.

The Krom equipment consists of a battery of circular cast-iron pans. The circular form of the pan has the following advantages:

First—The suction-draught. The bottom or grate portion of the pan is adapted to a cone-shaped sheet-iron extension, from the apex of which the suction-draught is drawn. This construction ensures an even draught of air through all portions of the sinter charge resting on the pan-grate above; on account of this construction the pans can be made of a size to suit as small or as large a capacity as the operation may require.

Second—Charging the pan. The circular form of the pan allows the charge to be quickly and evenly distributed without compression or packing, and is accomplished by a rotary distributor.

A motor-driven traveling igniter equipped with burners for gas or oil, which cover the entire surface of the pan, is used.

Discharging is accomplished by a new method, namely, the retaining walls of the pan holding the charge on the grate also form a motor-driven ram for pushing off the finished sinter. The rim or the retaining wall of the pan is mounted on wheels and is provided with a cast-steel plow. This plow travels clear of the grate section, ripping the sinter cleanly from the grate and at the same time breaking it into desirable sizes. The discharging operation is entirely automatic, fast, and positive in its results.

COMMERCIAL PARAGRAPHS

Bulletin 246 of the Dayton-Dowd Co. describes sundry types of centrifugal fire-pumps manufactured at the company's plant at Quincy, Illinois. These pumps have been

tested and approved by the National Board of Fire Underwriters.

The Universal Portland Cement Co. announces a reduction in its selling prices for Universal portland cement, effective on September 15, of 20c. per barrel at its Chicago plant, and 15c. per barrel at its Pittsburgh and Duluth plants. This is the second price reduction made by this company this year.

'The Variety of Design in Furnaces' is the title of Pamphlet No. 232, recently issued by the W. S. Rockwell Co., manufacturers of industrial furnaces. The company makes furnaces of several hundred different types and designs and is prepared to supply the most suitable installation for any required purpose. The question of ultimate efficiency of operation is discussed in this booklet. It is pointed out that the advantages of adapting industrial heating equipment to the manufacturing requirements and plant conditions in each individual case are not always appreciated. Consideration only of strictly thermal features of the operation is often responsible for failure to effect the economies which, almost without exception, may be brought about by intelligent selection, arrangement, and operation of equipment properly adapted to the individual plant conditions.

'Storage-Battery Mine-Locomotives' is the subject of leaflet 1888-A, which has just been printed by the Westinghouse Electric & Manufacturing Co. This leaflet describes the applications of storage-battery mine-locomotives and illustrates and treats on the Baldwin-Westinghouse type of apparatus. The storage-battery locomotive is particularly adaptable to 'gathering' service and underground haulage, where there are difficulties in erecting and maintaining trolley-wires and in bonding the rails, or where wooden rails are used. It is also suitable for general work on the surface, by the addition of a cab or canopy. Operating under any of the above conditions, it is entirely reliable and very easily operated. The salient advantages of the Baldwin-Westinghouse storage-battery locomotive include accessibility, simplicity, efficiency of operation, and general ruggedness of design. The mining type conforms to the principles established by years of experience in the successful application of mining locomotives of the trolley-type and the construction follows that type as closely as possible.

Mine operators will be interested in learning that the Treadwell Engineering Co., of Easton, Pennsylvania, has placed on the market a new line of hoists, both steam and electric driven. The company, while a long-established and well-known manufacturer of rolling-mill equipment, has not hitherto been so closely identified with the mining field. The company feels that it has been fortunate in securing the services of Thomas O. Werner as chief engineer of its hoist department. Mr. Werner is widely known as a hoist expert, having been associated with the S. Flory Manufacturing Co. in a similar capacity for many years. Among the features which distinguish these new hoists is a double-toggle clutch mechanism which is claimed to be a step forward in design. The clutch is usually mechanically operated by a double-acting cylinder, although it can be arranged for hand operation if desired. A point is made of the fact that the clutch (of the hand-type) drives directly from the rim of the main gear, which carries the driving portion of the clutch, to the friction-flange of the drum. The construction necessarily eliminates any torsional stress in the drum-shaft, and end-strain or thrust in the bearings or operating mechanism, for when brought into play this device is automatically locked. The company is building a complete line and is prepared to offer a machine to meet practically any operating conditions within a range of from 100 to 300 hp. These hoists can be arranged for either electric-motor or steam-engine drive.

T. A. RICKARD, . . . Editor

BRITISH participation in American mining has been diminished by the transfer of the Arizona Copper Company's property to the Phelps Dodge Corporation. The terms have been published in our news columns; they are said, by the 'Financial Times' of London, to be disappointing to the British shareholders of the old company, because the shareholders receive only the equivalent of £1,800,000 in exchange for property that not long ago was valued on the Stock Exchange at £3,000,000. Unfortunately for the former shareholders the deal was made at a time when copper mines were at a discount. We congratulate the Phelps Dodge directors on their courage and enterprise.

EXTENDED use of copper and other metals will result from the electrification of railroads, which is as inevitable as was the substitution of the incandescent lamp for the candle. Chile is taking advantage of the low price of metals, the government of that country having recently signed a contract with the Westinghouse Electric & Manufacturing Company for the equipment needed to electrify the State railroad between Valparaiso and Santiago. The cost of the material is \$7,000,000, and the contract is said to be the largest of its kind that has been signed since the War. With a little more initiative of a similar nature in other countries, the present period of stagnation in the metal market would soon be passed.

BLESSINGS are often disguised, it is said. We have not the temerity to suggest that the 12½-cent copper market is a blessing, even in disguise, to the producer of the metal; but some consolation can be gained by looking at it from a certain angle. If copper is cheap, things made of copper should be cheap. People know that articles made of copper and brass are superior for many purposes, and, if the price is low, they will be inclined to purchase manufactures of these materials. They will then appreciate more than ever the economy of using high-grade articles and will continue to buy when the price is increased somewhat in conformity with a reasonable advance in the quotation on raw copper. They will form a copper-using habit, and such a habit is as potent an ally as any commodity can have. It may be argued that the longer copper stays at 12 cents, the stronger the

habit will become; the trouble is that then the cure would be worse than the disease.

OUR figures (in the issue of September 21) for the total stock of copper on hand were, we find, incorrect; for the reason that no account was taken of the unrefined metal in smelter yards. The U. S. Geological Survey gave the stocks on January 1, this year, as 659 million pounds and the unrefined copper at the smelters as 465 millions, making a total of 1,124,000,000 pounds. On September 1 the total is estimated to have been reduced to 810 millions. Sales for September are estimated at 100 million pounds, whereas production was about 40 millions. At the current rate of relative production and consumption, the surplus at the end of the year should be about 650,000,000 pounds, or only 250,000,000 pounds in excess of the normal quantity in course of refinement.

AN editorial in a recent issue of the 'Journal' of the Society of Chemical Industry affirms that the scope of that institution is "not merely imperial in character"; with its large and enterprising membership throughout the North American continent it gives a practical demonstration of the preliminary success attending community in language, in political ideals, and in scientific development; such an alliance between the United States and Great Britain presents the best hope for permanent peace. Sir William Pope, the retiring president, recently in New York, has rendered a valuable public service in his frank criticism of those who are disinclined to review the physical and chemical basis of existence, or to provide the scientific requirements for its continuance. In spite of the daring and ingenious forecasts made in regard to the latent possibilities of intra-molecular energy, no attempt has been made to harness it. Pending such a consummation, solar energy remains the only source at our disposal; and if the multiplication of government departments were an outward and visible sign of an inward and scientific grace, a nation that first established a Ministry of Radiation might reasonably claim to be the best fitted for racial survival. The experience of a century, however, has taught scientific men that no reliance can be placed on such lumbering and creaky machines for accelerating progress. Our hope,

says the 'Journal', lies in that characteristic of the English-speaking peoples that, emerging from the crucible of a thousand years, has enabled them, during that period, to spread their ideals throughout the world. Adaptability to circumstances, the capacity to face an issue, the patient determination to solve a problem, combine to form an attitude of mind that inspires us to envisage the future without dismay. Scientific enthusiasts will continue to plod their laborious way through the labyrinths of nature's mysteries. Many will spend their lives, as heretofore, revealing secrets that add but little to the sum of knowledge. Occasionally some great truth will be brought to light, and its appearance will wring appreciation from an otherwise unheeding world. Gradually, but inevitably, the system of education will be modified to embrace the fundamentals and to shed the frills; and civilized man will awake to a vision that discerns in clear perspective the real problem he has to solve, and will adopt the only principles by which he can solve it. The chemists are to be congratulated on the firm establishment of a technical society that embraces membership throughout the English-speaking world. This will aid in the attainment of that goal—peaceful progress—for which we all strive, whether we were born on this or that side of an international boundary.

CAPITULATION on the part of the Southern Pacific Company has ended a short but bitter controversy between the railroad corporation and the mining towns of southern and western Nevada. A petition of the company that sought authority to curtail the daily passenger service between Reno and Mina to a schedule of three trains weekly was withdrawn voluntarily on the eve of the hearing before the Nevada Public Service Commission. For twenty years the Southern Pacific Company has maintained daily Pullman service to Mina and thence to Tonopah and Goldfield over the T. & G. tracks, but on September 2, last, notice was served that it desired to curtail this service; the Commission designated September 20 as the date for a public hearing on the petition. The ground for the request was decreased patronage, which made the operation of seven trains per week unprofitable. The Tonopah & Goldfield Company's trains, obviously, would have had to be discontinued to conform with the Southern Pacific schedule. The announcement evoked a storm of protest from a dozen mining towns, led by Tonopah, Mina, Goldfield, and Yerrington, whose business is conducted largely with firms at Reno and San Francisco, and whom therefore any irregularity in the mail and passenger service would inconvenience seriously. Dispatches from Tonopah say that "pressure was brought to bear", from which we infer that a transfer of commercial relations from San Francisco firms to those of Los Angeles was suggested, for the Santa Fe railroad runs trains from Los Angeles to Tonopah by way of Ludlow, where junction is made with the Tonopah & Tidewater line. Besides suffering direct loss of revenue from the possible diversion of freight, the Southern Pacific Company apparently was confronted with the necessity

of propitiating the shippers at Reno and San Francisco whose business might suffer. Whatever the reasons may have been, the company decided to withdraw its petition and to "carry the loss sustained by operating these trains for a reasonable length of time, although the officials were not at all fearful of the outcome of the impending hearing". We do not know how great this alleged loss may be, but we believe that the districts served by the railroad have every reason for anticipating increased prosperity, and that the friendship of the residents will be an asset to the company. In Nye county alone the 'camps' of Silverton, Arrowhead, Clifford, Silver Bow, Bellehelen, Argentite, Manhattan, Weepah, Klondyke, Lone Mountain, Golden, and Divide are the scenes of active development. Within a radius of 50 miles of Goldfield, in Esmeralda county, four promising districts are being developed; and mining activity is greater in Mineral county than it has been for many years. The completion of the 150-ton mill of the Simon Silver-Lead company had stimulated the development of a dozen properties. In our opinion the Southern Pacific Company will find that the goodwill of the folks in southern Nevada will be worth more in dollars and cents than the cost of running the extra trains.

Lawlessness

When citizens take it upon themselves to be more legalistic than the officers of the law and more loyal than their representatives in the Government, it bodes ill to a democracy. Several examples of such perversity have been presented to the public lately. The Ku Klux Klan, under cover of a fraternity, with the rites of a secret society, the antics of a tribe of South Sea islanders, and the technique of a Red Cross drive, has gathered to itself a large number of misguided persons who have set themselves to discipline sundry communities by passing sentence upon individuals, subjecting them to tar and feathers, and inflicting other barbarous methods of punishment. Under cover of insignia, declarations, and regalia they condemn citizens by secret edict and without trial; and, forsooth, claim to be 100% American! By a reign of terror they undertake to administer the law; by flouting the law and committing crime they dare to pose as defenders of our democratic institutions. Next we have the affair in West Virginia, where the managers of coal mines operating on the open-shop system armed their men for the purpose of repelling the advances of unionism in the form of representatives of the United Mine Workers. The service of armed men was obtained by the operators under guise of hiring detectives, who were 'gun-men', of the same type as the 'strike-breakers' engaged by mining companies when a labor-union becomes obstreperous. To put it briefly, armed men were hired by the operators in order to close the 'open shop' and to exclude the emissaries of unionization, who thereupon armed themselves and started a civil war, to end which it became necessary for the President to send Federal troops to the coalfield. Both sides tried to secure their own ends by force, in complete disregard of the law.

More recently in our own State, in the Kern River oil field, the union men, in order to exclude non union men, armed themselves and terrorized the community. They 'held up' travelers on the high-road and talked in terms of organized warfare. These antics were facilitated by means of a legal subterfuge, whereby the sheriff appointed the men as deputies and thereby gave them the right to arm themselves and to interfere with the movements of their fellow-citizens. The 'deputies' in California were analogous to the 'detectives' in West Virginia; in both cases they were law-breakers masquerading as the upholders of the law. These affairs, as also the Bisbee deportations of July 1917, are manifestations of a spirit subversive of our democratic institutions, whether those responsible for them be officials or private citizens, educated men or hoboos, union men or non-union men, natives or aliens; each of these episodes is a slap at the fair face of democracy and an insult to the national flag.

To correct this orgy of lawlessness there is needed a healthy public opinion, and to develop that we need an honest and fearless press. Unfortunately most of our newspapers are committed to one or the other side in the industrial conflict, and most of them represent the employer class, so that impartial criticism is rare; nevertheless it is certain that in the end the weight of public opinion is decisive, and therefore any wrong doing or unfairness on either side would win public reprobation if only the facts were made known. There's the rub; some journals are so prejudiced, so committed to a partisan view, that they do not even give their readers the facts upon which a just opinion may be based. For example, the 'Mining Congress Journal', which ought to be spokesman for the enlightened opinion of those engaged in mining, is unable to discuss any labor problem except from the point of view of a Vanderbilt, a Baer, or a Gary. In its current issue it travesties the facts of the West Virginia affair and then proceeds to describe the efforts of the United Mine Workers to unionize the coal miners in the following terms: "They were outsiders, aliens who sought to drive out the inhabitants and possess themselves of the land, and they had exactly the same justification for their conduct that the Moorish hordes had for invading Spain, that the Tartars had for over-running northern Europe, and that the Germans had for blasting their way through Belgium". This sublimated piffle might have been written by a very young man under the combined effects of three mince pies and two pints of hooch. The Mining Congress is woefully mistaken in supposing that such stuff, and such a mental attitude, will serve to disentangle our economic troubles or lessen the friction arising between employers and employees in the industry of mining. Its attitude on the labor question has been narrow and perverse; it provokes lawlessness instead of allaying it; it obscures the real issue with sophomoric digressions that are as ridiculous as they are inappropriate. It fails to represent the men of the mining industry, to whom such antics are repellant. The violent language it uses—the language of a reckless and

ignorant schoolboy—will settle no labor trouble, for it bears no trace of sober thought nor will it stop lawlessness, for it breeds more mischief. The questions involved in these matters are complicated enough already without the injection of an ignorant venom, if they are to be settled, for the good of the community as a whole, they must engage the best thought of the most thoughtful men, not the silly vaporings of an irresponsible scribbler.

Hunting for Ore

In the current issue of 'Economic Geology' Mr. Augustus Locke contributes a striking and thoughtful article on the profession of ore-hunting, as he terms it; and many of his arguments should provoke discussion. He introduces the subject by stressing the point that commercial mining geology has failed to reach the research stage; no adequate financial support for broadly planned experimental operation has been forthcoming, because the application of geological knowledge and experience is not generally accepted as the best method for the discovery of ore. Chief among the reasons for this is the fact that it is inconspicuous. The adoption of rule-of-thumb methods and the development of surficial ore deposits have resulted in the establishment, in this country, of the greatest mining industry in the world, but the time has come when fresh discoveries are increasingly difficult to make. It is probable that few great deposits remain that may be found by ordinary prospecting or because they are plainly indicated by outcrops. The application of a new commercial geology is imperative; this must rely for its success primarily on research. The work will be done through three main groups of specialists—chemists, structural geologists, and mineralogists, respectively. The success of the scheme will depend to a large extent on the geologists themselves, for it is essential that they stimulate the spirit of research within the profession. They can preach its necessity; they can refuse engagements proposed under a meagre scale of pay; they can insist, when conditions are promising, on enough capital for an adequate investigation; they can undertake research on their own initiative in subjects of commercial interest. Thus will they be able to destroy the charlatan, betray the parrot that talks like a man, and distinguish the result of the lucky guess from the well-planned technical achievement. The outstanding impediment in mining geology, we are told by Mr. Locke, is the lack of a special technology devoted to the subject of hunting for ore; geology, as a guide to ore, is without a literature; it needs the inventive spirit. This question leads to a consideration of what is known as the scientific ore-hunter, who is inclined too often to disguise vagueness by means of scientific jargon; others of the same type speak and live by the book alone. These men, as Mr. Locke remarks, give to science a look of futility, the cause being, not science, but a lack of science; for the opinions of the real scientist will carry conviction to the coldest business man. However, even toward the best type, the operator's antagonism remains; the result will be the hindering of appropriations to the real geologist.

The money needed, Mr. Locke argues, must come from the mining companies; it is the geologist's task to prove that science is needed in the work of hunting for ore. In an attempt to determine the cause of vagueness in commercial mining geology it is pertinent to note the author's opinion that an adherence to *a priori* methods is largely responsible; a greater degree of empirical reasoning is needed, based on actual evidence, actual examples, and actual enrichments. Moreover, the geologist should have a mind that is sufficiently fruitful to supply the necessary hypotheses, and an activity that is relentless in testing their accuracy. Above all, there is need for men who possess both the positive and the imaginative knowledge of conditions in a large number of mining districts; such a man needs a shrewd schooling in half the mines of the country. The second most important reason for habitual vagueness is the frequent failure on the part of the geologist to confine himself to the actual purpose of the work, which is to supply information cheaply. For instance, in many cases a report that wanders off into a discussion of considerations other than of grade is essentially defective; it is answering questions that never have been asked. In every report there is scarcely a turn when the dominant theme cannot be developed; every sentence should be purposeful. The history of a prospect, for instance, should contain an explanation of events, not merely a chronicle of them. The introduction of controversial matters should be avoided. With notable exceptions, among which may be mentioned the work of the Anaconda Copper company, geological maps are loaded with answers to questions that never have been asked. Thus it is that lack of financial support is due to a neglect on the part of the geologist to understand the requirements of the operator. A geologic report should carry the mind of the reader to an effective conclusion; it should focus the attention, of the writer as well as the reader, on those considerations, chiefly empirical, that are connected with the discovery of ore.

A third reason for the vagueness in geological reports is due to the practice, especially common among those of immature judgment, of stating conclusions without mention of the degree of doubt without which they cannot be accepted. Failure to express the degree suggests a failure to estimate it; speculation, qualified by a clear indication of the degree of doubt, should be the soul of the report. The more active-minded the writer, the more thought he exhibits, the greater the conviction he carries. Geology may be defined as a speculation with its more fantastic parts removed; its fundamentals should be advanced in such a manner that attention is focused chiefly on probabilities defined by empirical evidence. Another source of vagueness is found in the degree of incompleteness that characterizes many reports. Absolute completeness is, of course, unattainable, but a geological report should include all pertinent considerations; it may be accepted as complete when, after repeated study, no new vital matter is added; stability of opinion is reached. The result cannot be accomplished in a hurry; it takes time and thought. The final

cause is described as arising from isolation of opinion. Secrecy occasionally means dishonesty; often it denotes ignorance. Mr. Locke advises the young geologist to spend at least half his time in preparing his arguments in a clear and complete condition. If this advice were to be taken seriously, much half-baked material would never be submitted or published; moreover, opinions and deductions of value would be forthcoming in greater quantity. Mr. Locke's comments on this phase of the matter are true and forceful. A staff geologist, he says, who has no desire to publish is unlikely to do important geological work; a mining company would do well to rebuff the secret worker; it should raise an employee's pay when he can write a good article that attracts attention and invites the opinions of others. Such co-operation, however, must rest on positive ability; it involves the cultivation of a sense of genuine intellectual fairness—a fairness that should be made positive, even aggressive; in this sense it is an important factor in ore-hunting. Geology is no place for harsh difference of opinion; the worst aspect of apex litigation lies, says Mr. Locke, in its encouragement and conspicuous exemplification of antagonisms of such a character, which, incompatible as they are with the progress of the profession, become highly profitable to sundry technicians, in fame as well as in money. Apex litigation is the enemy of co-operation; in that sense it is the enemy of geology. The controversial spirit poisons thinking; trammelled with prejudice, error may result. In short, the geologist must subordinate temperament to logic; it is as well to avoid the man who is always seeking preferment for his own mental offspring. The record, insists Mr. Locke, is an integral part of geological work; it must possess, in order to carry conviction, a greater proportion of intrinsic logic than the spoken word, for the personality and the magnetism of the speaker are not available. The writer must establish the conviction that he is sincere, fair-minded, and competent. He will avoid the careless use of superlatives. One of the indications of shrewdness is a sense of humor; the writer should never be so dull as to remain unsuspecting while the reader laughs. On the other hand, he should never commit the sin of boring his audience. In conclusion, Mr. Locke draws attention to the difficulty in finding competent men. A disadvantage arises from the fact that geologists who have achieved success are removed by what he terms 'decantation'. No able man will be long content with the routine, the cramped authority, and the small pay that characterize the usual staff job. When the average geologist reaches the consulting class it is an index that he is competent. He often possesses business ability in addition to technical ability, and is tempted to utilize it in other directions. He becomes a manager or an owner of a mine, or an editor; his career as an ore-hunter stops abruptly. Thus there is danger that the profession will retain only those that are incompetent in business matters. So long as ability is wary at the entrance and adroit at the exit, the personnel of the profession of economic geology will remain of poor average quality.

DISCUSSION

Valuation of Placer Deposits

The Editor:

Sir—Mr. Gerald H. Hutton's article in your issue of September 10 constitutes a valuable contribution to the literature of gold-dredging.

The methods that Mr. Hutton describes for correcting possible errors in drilling of placer deposits are interesting and important, but I believe it is seldom that so many safeguards are employed. The average driller measures the core before and after he has driven his pipe and after he has drilled the core, contenting himself with noting in his log the height of the core, and paying no attention to the amount of slime produced by the drilling of the core.

In explanation of, and apology for, this seeming carelessness in the handling of the core material, it must be borne in mind that the drill-pipe cannot cut a true cylinder from irregular ground that consists of sand, gravel, stone, and occasional boulders. Hence the sample taken cannot accurately represent the opening made by the pipe, as it is certain that many stones encountered by the shoe must be driven into the bank or into the pipe, whereas the stone should have been cut in two. The impossibility of making a true section of the ground is an excuse for the apparent carelessness in handling the sludge derived from the hole.

Mr. Hutton's suggested method for arriving at the average value of a number of drill-holes is a valuable one. The cancellation of a low hole as against a high hole appears to me to be warranted by the experience obtained in the field. In the case which he mentioned, and of which he gives a graphic illustration, he has canceled two high holes against two low holes, using the metal-values of the holes instead of the multiple obtained from depth multiplied by value.

It would be interesting to know how this graph would look if Mr. Hutton used this multiple ($D \times V$) instead of the value alone. It often appears that the highest value is obtained in a shallow hole on account of the lack of barren overburden or on account of an accumulation of gold upon a high reef of bedrock, and therefore, this multiple ($D \times V$) would not make as high a peak in the graph representation of the drill average as would be shown by the plotting of values alone.

The example given by Mr. Hutton shows an actual average on the 23 drill-holes, accepting them to be of the same depth, of 14.09c. After eliminating the two high holes and the two low holes, the average is 8.46c. I believe that had Mr. Hutton used the $D \times V$ figures in his graph and in his elimination, he would have obtained a somewhat different average value for the 23 holes and it

would be interesting to know what that figure thus obtained would be. In my own practice, I usually made the first estimate of the average value by the usual method, figuring $D \times V$ on all holes and dividing the total of $D \times V$ by the total of depth. In this calculation, I included all holes, high and low. If there were any freak holes, I then proceeded to deduct from the total $D \times V$ the value of these high holes, and in place of these high $D \times V$ values, substitute the average value obtained from all holes. Add these $D \times V$ figures again and divide by the total depth to obtain a new average. If I used this same method upon the 23 drill-holes presented by Mr. Hutton, I find the following figures:

The total of all his values is 324. Deduct from this the two high holes, $114 \div 45$, or 159, it leaves us 165. Add to this twice 11.1 (the average of all holes) and we have a figure of 193.2. Divide this by 23, and we get an average of 8.40c., as against Mr. Hutton's average of 8.46c., which is a close check.

In studying Mr. Hutton's algebraic calculation to arrive at the number of yards represented by a high hole, he assumes that holes 'A' and 'B' represent 20,000 cubic yards each, and I would prefer therefore, to start with the equation, 'A' plus 'B' equal 40,000 cu. yd., not 20,000 cu. yd. This substitution carried throughout the calculation gives us a final value of 'B' equals 37,692.8 yd. and 'A' equals 2,307.2 yd. These figures give the algebraic quantity of material contained in 40,000 yd. represented by the two drill-holes of high and low metallic contact. While these figures are correct algebraically, I cannot bring myself to believe that a hole showing \$144 per cubic yard in an area representing 20,000 cu. yd. will ever deliver 1153 yd. of average value indicated by the hole.

After dredging through a number of such enticing patches and holes, with much disappointment as to the results, I have come to believe that a high freak hole represents a very small area and should be either eliminated entirely, or discounted, as I have suggested heretofore.

San Francisco, September 14.

Revision of the Mining Law

The Editor:

Sir—In discussing the proposed new mining law there are several points that your correspondents do not seem to have covered.

At the present time, I think it is safe to say that the average location survey, 600 by 1500 ft., can be surveyed and staked in half a day. Actually to tape a location through timber would take longer perhaps; for stadia

measurements on the desert, less time would be required.

If under the new law the claim must be surveyed by legal subdivision, let us take as an example a section where all the corners are easily found, as is rarely the case, but no quarter-corners can be found. To survey this section properly and cut out a given area would require 6 miles of surveying at least, and probably take on an average 3 days with stadia and 6 days with a tape. The work of surveying will be greatly increased if the corners cannot easily be found and this is usually the case. This means that the claimant's surveying would cost from 6 to 12 times as much as it does at present. I have in mind an area of country in Garfield county, Colorado, where there are no section-corners within 6 miles and where the survey of about 20 oil-shale placer claims has already cost something like \$1500.

If in the example used above the quarter-corners can-

not be found and are replaced according to the rules of the General Land Office, it is possible that years afterward some one will dig up a lost quarter-corner and make all the previous work of no value. It is always necessary to keep this possibility in mind.

Take the case of a flat vein dipping 45° and striking north-east as shown in the accompanying sketch. Suppose the claimant wishes to take up this vein for 3000 ft. in length, and provide for working it to a vertical depth of 2000 ft. It will be necessary to locate 240 acres as shown, when all the ground really needed is about 138 acres. The surveying would be difficult, as practically the whole section would have to be surveyed. The necessary dip calculations would be beyond the uneducated man. If the ground is patented, the owner will have to pay taxes on 240 acres in place of the 138 acres that he really wants.

In most counties in Colorado the greater number of patented claims are actually paying taxes on about 10 acres for each lode claim; in four counties, on 5 acres only. Under the proposed new law, in order to get the rights to one of these lodes on the dip it may be necessary

to take up 100 acres and pay taxes on from 5 to 20 times as much ground.

This wholesale taking up of land will probably cause the Forest Service to sit up and take notice, for whereas the locating of 20 acres as at present is a relatively small matter, the Service would probably 'view with alarm' the taking up of areas in lots of 160 acres, and prevent the location and patenting of many promising lodes.

If it is desirable to do away with the extra-lateral right and have a square location, then some of the difficulties of the proposed law might be obviated by providing that such square locations need not necessarily be laid out along cardinal lines, or according to legal subdivision of the public land survey. A survey of this kind could be made by any one with a slight knowledge of surveying, and, aside from taking a little more time, could be made as easily as the location of claims at present. Such claims could also be laid out easier where it was desired to cover fractions of ground. Under the proposed law, to cover a certain unlocated fraction it might be necessary to lay out four 10-acre lots, where perhaps only one acre was desired.

The provision requiring that claims shall be filed with the Land Office may be wise, but it leads to double expense. All locations that change hands will also be filed necessarily with the County Recorder, or some such officer, just as patents are now, or it will be impossible to preserve the chain of title or get an abstract for any piece of land.

In short, every step that the locator takes under the proposed law will cost him from two to ten times what it costs at the present time, and the only gain as far as I am able to see will be the doing away of the extra-lateral right. The extra-lateral right has been one of the greatest incentives to prospecting in the past, and with that gone and the other features of the new law in operation, we can foresee an end to prospecting, or at least such prospecting as we have had up to the present time.

JAMES UNDERHILL.

Golden, Colorado, September 20.

The Editor:

Sir—It seems to me that Mr. Spear, in a recent letter to you on the subject of the proposed new mining law, makes a strong criticism when he points out the difficulty of finding Government corners. The fact of the matter is that the Government land surveys exist for the most part on paper only. This means that a prospector, in order to make a location under the proposed law, must hire a surveyor. If the time necessary for a Deputy Mineral Surveyor to locate a Government corner in the average patent survey is a fair criterion, it would require about three days to tie-in isolated claims. In case the locations were on so-called unsurveyed land, this time might easily extend to as long as ten days.

Reduced to dollars and cents, this means simply that in case the Bureau of Mines law passes, it will cost a prospector anywhere from \$75 to \$250 to make his location. This literally eliminates probably 95% of the pros-

pectors, for they are notoriously impecunious. Still *they do find the mines.*

The only good point in the new law is the one that eliminates the apex.

Luning, Nevada, September 25.

Indexing Current Technical Literature

The Editor:

Sir—May I add the following to my letter in your issue of September 17?

The 'Press' is not alone in its appeal for a complete index of technical articles, as witness the following editorial from 'The Iron Trade Review' of September 1, 1921:

"Announcement is made of the Index of Transactions of the American Foundrymen's Association, which has recently been published by that organization. The preparation of this book is an important achievement, and the directors of the Association are to be commended for their thoughtfulness and vision in authorizing the work.

"Although a great amount of valuable information has been contributed to the literature of the foundry industry, its usefulness has been seriously impaired by its inaccessibility. Unless a person has had unusual facilities at his command, it has been difficult for him to obtain an extensive list of references on a particular subject. The annual indices of the transactions of the various organizations which touch upon the foundry industry are of little value in compiling a bibliography on a single topic, and the volume indices republished by the trade and technical papers likewise are not satisfactory in collecting references covering an extended period of time.

"The index prepared under the direction of the American Foundrymen's Association covers the vast number of technical articles appearing in all of the volumes of transactions of that organization that are in existence. Since it is the intention to revise the index at periods of about two years, it can be seen that foundrymen, metallurgists, and others interested, are assured of a complete bibliography which will be kept up to date. The book has the distinction of being the first of its kind to be published by a technical organization identified with a single industry. *It is to be hoped that other societies will find it possible to follow the example of the American Foundrymen's Association* [the italics are mine], and will compile indices which will open to engineers in other industries that vast amount of information which now is comparatively valueless because of its inaccessibility."

How well this applies to the mining profession needs no further discussion; it bears out your editorial on the subject. To enable this work to be accomplished, the Board of Directors of the American Foundrymen's Association at Pittsburgh in December 1919 gave its secretary, C. E. Hoyt, authority to engage a librarian to prepare a page-to-page index of all available volumes of its Transactions, there being from 9 to 29, inclusive, pre-

sumably 21 years. It is admitted that the tendency was to over-index rather than to cross-index too sparingly. An author's index forms part of the publication, as many engineers remember articles by author's names. The index is 6 by 9 in. size, 192 pages long, and is bound in cloth.

On further consideration of your editorial, and of what the American Foundrymen's Association has done, I do not think that an index for the mining profession could be compiled satisfactorily by voluntary effort, as is the case with 'Chemical Abstracts' of the American Chemical Society. No doubt able engineers could be selected—you gave Professor Probert a hint to busy himself on 'Outcrops'—but the best way would be to appoint somebody who knows what the mining profession requires; who understands mining and metallurgy generally; who has a knowledge of mining in foreign lands; and who is conversant with the technical press.

As I said in my previous letter, the American Institute of Mining and Metallurgical Engineers is the logical organization to do this work. It has access to a great technical library; it could circularize members as to the demand for an index; and could appoint somebody for the purpose. It would not necessitate any further call on members of the Institute, as the publication should be self-supporting.

M. W. VON BERNEWITZ.

Washington, D. C., September 20.

Valuation of Ore

The Editor:

Sir—Is there anything new or of value in the following method of estimating the value of placer deposits or the value of ore in a mine? Is the principle correct?

In order to ascertain how much a body of ore or a deposit of gravel will pay, it is first necessary to determine what is the lowest grade of ore or gravel it will pay to work. At first sight one is not likely to see how important or how difficult this is. If we work all the ore or gravel in sight we may easily work a lot of material that will not pay—a lot of material that will absorb a great deal of the profit that might otherwise be made out of the deposit. On the other hand, we may, if we are not careful, in an attempt to cut out ore that does not pay, leave ore that will pay. The problem is how to determine with certainty, instead of in an arbitrary manner, as is often done, the ore or gravel that will pay. The lowest grade it will pay to work is always lower than the average cost of production, which is often taken as the basis of calculation. The average cost of production does not tell us how low we can go.

The lowest-grade ore or gravel that will pay to work is the grade, when worked at the same time and in connection with the higher-grade ore (worked as a side-line or a by-product), that will pay the wages of the men who take it out, for the tools they use, a portion of the wear and tear of the things they use in common with those taking out the higher-grade ore, and a fixed rate of in-

terest. No expense such as roads, houses, administration, superintendence, or plant, such as ditches, dams, flumes, mills, hoist, etc., should be charged up to the cost of taking out the low-grade ore or gravel. No expense should be charged other than the extra expense due to the extra production.

A deposit of gravel that will pay to work must have enough gravel above the value of the lowest grade to pay for equipment, current expense, and a fixed rate of interest.

Much of the expense will be incurred whether the low-grade is worked or not. You proceed as if you already had your mine opened up and your plant built and your organization formed. You proceed as if these had been given you free of charge. No past expense is considered, only the extra future expense is considered in figuring the lowest-grade stuff it will pay to work.

It is here assumed there are no limiting factors except those due to the orebody itself—no limiting factors such as the lack of capital, the lack of water, the lack of labor, the lack of fuel. A lack of capital to furnish the proper machinery and to do the necessary development work will raise the grade of the ore or gravel it will pay to work. The lack of water, of fuel, or of labor will do the same thing. What we need is the factor in determining the lowest-grade ore it will pay to work. Capital is essential, for it will do more than anything else to supply the deficiencies. This is a crude and an inexact way of putting it, but, I think, will give some idea of the principle. The idea here is much the same as that expressed by Mr. J. L. Bruce, in your interview with him, in which he says, "Any well-organized mining company is in a position to utilize its existing organization with comparatively small additional expense as compared with a new organization and with much better efficiency".

It is cheaper and more profitable to work this low-grade stuff while working the higher than to come back afterward and work it; it is cheaper and more profitable per ton or yard to work it than to exploit an entire deposit of equally low-grade stuff. It is a business proposition. It is a question of making the most efficient use of overhead expense. Business may be defined as the science of the overhead. In other business when it is desirable to know whether any side-line or by-product is paying or will pay, we deduct the expense of the business without these from the expense of the business with them. The difference tells the tale. In figuring the selling price the whole expense is distributed.

WM. CROCKER.

Prescott, Arizona, September 19.

Gold in Black Sand

The Editor:

Sir—I am gratified at the wide-spread interest in my work, as shown in the numerous letters I have received, and by Mr. Perret's contribution to your columns from Yokohama. I have just made this test: Seven pans of gravel gave 208 colors weighing $1\frac{1}{2}$ grains, equivalent to \$1.50 per cubic yard. I have found that taking medium

sealy colors, discarding shotty colors, and fly-specks, they range from 213 to $1\frac{1}{2}$ grains. We then rocked a measured cubic yard of material for 40 gr. (\$1.50), which, allowing for an inevitable loss in rocking, is rather better than the pan.

We saved 46 lb. of concentrate in the clean-up, which contained 63.1% of non-magnetic material. Part of this was pulped; it assayed \$1014.66 per ton in gold, platinum, and iridium; 63.1% (\$640). A test of the tailing from the rocker showed a loss of over 50 lb. of black and gray sand, though of less value than the recovered portion, it is fair to take 50 lb. in lieu of 46 as the recovery, which gives an average of \$16 per cubic yard that would be lost by ordinary placer-mining methods. I have found considerable precious metal in the red and gray sand, which is of almost the same specific gravity as the black sand, and this accounts for the large proportion of concentrate per yard.

We have a big body of rich gravel, but are handicapped by lack of fall. We have to pump our water by electric power, so that economy is the first consideration. The bed of the present river is conglomerate, which rises under the bank to within six feet of the surface, 25 ft. above summer level, runs flat for a few feet and then dips and forms the bed of the ancient channel. This is about 30 ft. deep and carries 15 to 25 ft. of pay-gravel, with about 6 ft. of sandy loam as an overburden. As the result of months of careful experiment, we have decided to erect the following plant:

A Sauerman drag-cable elevator will be worked by an electric hoist; capacity, one yard per minute. The bucket will empty on an 18-in. grizzly, over a hopper feeding a 16 ft. by 4 ft. trommel with $\frac{5}{8}$ -in. holes; the oversize to go to a conveyor for stacking, and undersize along a short length of flume with the usual riffles, to save the coarse gold, thence over two Neill jigs, which discharge to a tray with a Wilfley head-motion. Across one end of this a magnetic roller is spaced one inch above the material, and is revolved by a canvas belt. The magnetic sand goes to a short conveyor, and the non-magnetic to a 5 ft. by 3 ft. ball-mill, thence to a Senn pan-amalgamator, and over a Deister table. Roasting would give a better recovery of amalgam, but it would add greatly to the cost and complexity of the process, and break its continuity.

By passing this product over a table, what we lose on the swings, we will get on the roundabouts. All our power is electric, and on an output of 1000 yards per diem the estimated cost is 10 cents per yard. In designing the plant we gave no consideration to Berdan pans. I was under the impression they had been discarded in favor of ball-mills. I am inclined to agree with Mr. Perret that a Berdan would give excellent service on this type of material, and if one is procurable in the United States I would like to try it. This description is given in the hope that it may be of service to someone engaged in similar operations, and helpful criticism will be welcomed.

J. S. TAYLOR.

Rogue River, Oregon, October 1.

GENERAL ARRANGEMENT OF THE PRECIPITATING-VAT

Development of Copper Precipitating Apparatus

By Joseph Irving, Jr.

The first step in the development of the precipitating methods and apparatus, of which it is the object of this paper to illustrate, was taken at the Copper Canyon leaching plant of the Glasgow and Western Exploration Co., and was to a certain extent the outcome of a hurried adaptation of some apparatus that happened to be on hand, to overcome a defect in the original design of the plant.

The precipitating equipment of the Copper Canyon plant, as originally designed, consisted of a single launder, 4 ft. by 4 ft., 300 ft. long, divided into six equal sections of 50 ft. each, and set at a slope of 1.5%. Each section was equipped with a baffle and solution down-take at one end, and with a precipitate-discharge opening at the other, lower, end. The launder was fitted with a false-tray bottom, the top of which was set 7 in. above the bottom of the launder; this was so built as to hold the scrap-iron and to allow the precipitate to fall through and to collect on the bottom of the launder. The precipitate was removed by sluicing, with a strong force of water, into a small 12 by 12-in. launder, laid alongside the precipitating launder, and so conveyed to a settling-sump. The iron was cleaned by hand.

At the start of operations in 1912 the launder-precipitating system was found to be inadequate to recover the copper being produced. Because of the situation of the plant and because of the time needed to order and erect sufficient precipitating launders, it was decided to install temporarily three round vats, which happened to be on hand, at the lower end of the precipitating launder, and to fill them with scrap-iron. These vats, 20 ft. diameter by 8 ft. stave, were equipped with a false-tray bottom to hold the scrap-iron and to allow the precipitate to fall through and collect underneath. A solution down-take conducted the entering solution to a point below the tray bottom; a solution overflow launder was set into the side about 12 in. from the top, through which the solution left the vat. The vats were operated in series, and the results showed that a complete extraction of the copper was being made. As the operating costs were considerably lower than had been the case with the launder system, different sections of the latter were discarded, until the vats were recovering all the copper produced.

The efficiency of the vats led to experiments to devise a more satisfactory method of removing the precipitate than by sluicing out with water, the method first used.

Various devices were tried on both a small and a large scale, the one most favored, both for installation and operation, being the application of the Dorr-thickener mechanism to the vat, the arms of this being placed below the false-tray bottom, and rotated slowly, at intervals, to gather the precipitate to the centre and to discharge it through the opening in the bottom. This idea was adopted, and experiments were commenced on a large scale; but because of the liquidation of the controlling company, which took place about this time, the plant was closed down, and before the apparatus could be given a thorough trial. As the results obtained from the tests were satisfactory and promising, the idea was patented by me and the patent was assigned to the Dorr Company.

In 1916 I became mill superintendent at the copper-leaching plant of the Nevada-Douglas Consolidated Copper Co. At that time the plant, which was originally designed for the Rankin process, was being re-designed for the Westby SO_2 process. The method adopted for the recovery of the copper in the solution was precipitation on scrap-iron. Precipitating-vats, 20 ft. diameter by 10 ft. stave, equipped with false-tray bottoms and with solution downtakes, supplemented the launder system that was a part of the Rankin plant. It was thought advisable to erect only three of the vats at first, experimenting with them before equipping them with Dorr mechanisms, and before installing the other 10 vats that, it was estimated, would be required. As the process for the leaching of the ore was a new one, the different types of apparatus were erected and operated in units, so that mechanical defects could be rectified. This gave time in which to experiment with the precipitating-vat.

Experiments were carried out to determine the most efficient type of false-tray bottom, that is, a bottom that would allow the copper precipitate to fall through, but which would hold all but the smallest pieces of precipitant, and so prevent interference with the operation of the mechanism. A bottom built of 4 by 4-in. pieces of timber, set 4 in. apart in the clear, was found to give the best results. The provision of a peripheral-overflow launder increased the efficiency of the vat, due to the more evenly distributed upward flow of the solution through the iron and the absence of channeling. At first an ordinary Dorr-type launder was used, but was broken by the scrap-iron charged into the vat; and a new type of launder was developed. This is triangular in shape, with a smooth-covered top; it is built heavy enough to withstand the impact of the iron. The solution leaving the vat enters this launder through equally-spaced holes bored in the side; these should be set about 6 in. below the top of the vat, so as to be covered with solution. This launder provides a platform 18 in. wide around the outside; the operator can stand on this while arranging the scrap-iron in the vat. As the solution inlet holes in the launder are set below the level of the solution, any floating copper that is produced will stay in the vat until it is broken up and settles to the bottom. The

shape of the launder prevents the slopping of the solution over the sides, during agitation, and also assists (in conjunction with the cone bottom in the lower section of the vat) in creating a flow of solution during agitation.

Experiments were also conducted to determine if it were practicable to agitate the solution in the vats sufficiently to wash the precipitate from the iron. Different methods were tried, such as (1) the use of compressed air, the air being blown in below the false bottom and allowed to bubble around the iron; (2) the use of a pump with a flexible-discharge connection, thus permitting a strong stream of solution to be directed into the iron; (3) the use of agitation, by mechanical methods, of the solution under the tray bottom. The use of air, although efficient, increased the consumption of iron and was expensive. The pump was found to be inefficient. The agitation of solution by mechanical means under the tray bottom gave the most satisfactory results.

An incomplete-cone bottom was added below the false-tray bottom to assist in gathering the copper precipitate toward the centre, and in order to give the solution, during agitation, an upward movement through the iron at the outside, and, consequently, a downward movement at the centre. This scouring action is governed by the speed of the mechanism, and can be regulated as desired. With the cone bottom and triangular launder, a velocity of the solution sufficient to wash the precipitate from the iron could be secured with a small power consumption.

The Dorr mechanism was found to be suitable to the incorporation of both principles in the one mechanism, provided that the arms were designed properly; two speeds were necessary, one high enough to cause sufficient agitation to wash the precipitate from the iron, and one slow enough to gather it after it had settled, and to discharge it. A method of precipitation that would avoid many of the customary losses was developed. The precipitate was discharged from the vats into a separator, where the coarse or heavy material was settled and the fine or slime precipitate was allowed to overflow with the solution into a settling-sump. The fine material was thickened in this sump and discharged onto a drying-platform, the drainage solution from this going to the sump-tank. The overflow solution from the sump-tank was returned to the precipitating-vats. This solution was also used to sluice the copper precipitate out of the vats being cleaned.

The precipitating capacity of the vats was investigated. The largest amount of copper recovered in one day was 7147 lb., from a 2.72% solution, the extraction being 99.5%; the best results for one week showed that 31,348 lb. of copper had been recovered from a 1.604% solution, the extraction being 97.7%. The iron consumption was low, averaging for one month 1.15 lb. per pound of copper recovered, and for the following month, 1.05 lb. Although this low consumption was due in part to the favorable character of the solution (from the SO_2 leaching-plant, in which a small amount of SO_2 was always present), the practical success of the innovations sug-

gested by the experimental work had much to do with the result. The difference in iron consumption during the two months was due largely to the avoidance of unnecessary washing in one case. It was unfortunate that financial difficulties, caused by the abnormal conditions prevailing at that time, necessitated the suspension of operations before the plant was completed. The experiments, however, proved the decided superiority of the Dorr vat over either the plain-vat or a launder system. Tests conducted on different solutions have shown that a plain-vat system will precipitate from 75 to 200% more copper than a launder system of the same capacity, depending on the copper contents of the solution being treated. Other tests have shown that agitation, such as is used in the Dorr vat, for the washing of the precipitate from the iron, results in a precipitating efficiency per cubic foot of from 50 to 100% above that obtainable in a plain-vat system, depending also on the copper contents

bottom, and then up through the iron, it leaves through the overflow peripheral launder, into which it flows through the holes bored in the sloping side. A discharge launder takes the solution, either to other precipitating vats or as waste. The solution level in the vat is maintained constant by a baffle in the discharge launder, and should be kept a few inches above the inlet holes in the peripheral launder, in order to prevent losses from floating copper.

To wash the precipitate from the iron, the mechanism is raised off the bottom and rotated at a speed sufficient to ensure effective agitation. Although the amount and violence of the agitation required varies with the amount and quality of precipitate being produced, from one to two hours per day will generally be found to be sufficient. In a 24-ft. vat this speed is about 5 r.p.m.; about 1 hp. is required. The precipitate is discharged from the vat

RELATIVE EFFICIENCY OF VAT AND LAUNDER ON HIGH-GRADE SOLUTION

of the solution, and the frequency of the cleaning of the iron precipitant in the plain vat.

Fig. 1 shows the comparative results obtained between vat and launder systems on both high- and low-grade solutions. Fig. 2 shows the general design of the Dorr precipitator. All parts that come in contact with the solution are made of wood, or some acid-resisting material. The Dorr mechanism has been re-designed. The low overhead clearance and the type of support shown interfere as little as possible with the charging of iron when this is done mechanically, as is the case when the gantry crane is used for this purpose. The heavy wooden extension shaft and the lower wooden bearing increase the mechanical strength of the mechanism, and decrease the length of unsupported shaft. The discharge plug can be operated from the top operating floor or from under the vat. This plug is the result of various experiments, and provides the most satisfactory method of controlling the discharge of the precipitate. The downtake in the centre of the vat is provided with a ladder, to enable a man to get under the tray bottom to repair the mechanism or to remove iron that may interfere with the operation of the mechanism.

The iron is placed on the false-tray bottom until it is level with the top of the tank; the solution enters through the downtake manway in the centre, goes to the

RELATIVE EFFICIENCY OF VAT AND LAUNDER ON LOW-GRADE SOLUTION, BASED ON WEIGHT OF COPPER PRECIPITATED PER CUBIC FOOT OF PRECIPITATING CAPACITY

by lowering the mechanism and by rotating it at a speed that will not unduly agitate the material on the bottom, but will plough it to the centre and discharge it through the opening there. The frequency of discharge will vary, with the amount of copper being recovered, from once a day to once a week. The length of time required to discharge the precipitate is about two hours; the power consumption will average about 0.5 hp. The plant shown in Fig. 3 is of simple design and economical in operation. The use of a gantry crane for the unloading of the scrap-iron from the railroad cars, and its later charging into the vats, reduces manual labor to a minimum. The adoption of the Dorr classifier and thickeners, and the returning of all the solution from this section of the plant to the precipitating-vats, reduces the loss of copper to a minimum. The pregnant solution enters the plant at either or both of the first two head tanks. Cross-connecting launders are arranged so that it is possible to operate the vats either in parallel or in series. The barren solution leaves the plant from either or from both of the last two vats. The cross-connecting launders enable any one of the vats to be cut out, without in any way interfering with the operation of the remainder. The precipitate is discharged to a Dorr classifier, where the coarse portion is separated from the fine or slime, the former being discharged onto the drying-

platforms and the fine overflowing from the classifier to the Dorr thickeners. The slime precipitate is thickened before being discharged onto the drying-platform. The overflow from the thickeners goes to a sump, from which it is pumped back to the precipitating-vats; pipe connections are arranged so that this solution may also be used to sluice out and clean the vats when necessary. The solution drainage from the drying-platform is collected in another common sump under the classifier, and is pumped back to the classifier intake, ultimately going to the precipitating-vats. The slime precipitate, which contains about 80 to 90% moisture, on being discharged from the thickeners, is left on the platform about 10 days, during which time it will have drained and dried to about 35% moisture. The coarse precipitate drains rapidly to about 15%. The precipitate is shoveled into small hand-cars, which can be run alongside the drying-sections; and is later taken out and dumped where required. The scrap-iron is brought into the plant in cars on the upper railroad track, and discharged by the gantry crane directly into the vats, or onto the scrap-iron storage floor, where the crane can later pick it up and charge it into the vats. It is advisable, for the handling of small scrap, to provide the gantry crane with a magnet. In those cases where the precipitate produced is in a coarse condition and where atmospheric drying is not practicable, a filter can be used to handle the product from the classifier and the thickeners.

The costs of a plant of this kind will depend on the type of construction adopted. A well designed plant, such as is shown in Fig. 3, will cost about \$2 per cubic foot of precipitating capacity, completed. A comparison of costs between a launder system, a plain-vat system, and a Dorr system, using the same type of construction, will show that a plain-vat system is cheaper, per cubic foot of precipitating capacity, than a launder system; it is also cheaper per cubic foot than a Dorr system. But the increased precipitating efficiency of the Dorr system, enabling the same amount of copper to be recovered in a smaller plant, will more than offset this difference in first cost, making it not only more economical to operate, but also cheaper to erect.

The amount of labor required will vary with the amount of copper being produced, and with the copper contents of the solution being treated. In a plant recovering, say, five tons per day from a 1% solution, and of approximately the same size as the one shown in Fig. 3, five men per shift will be sufficient—one foreman, one man for the classifier and thickeners, one man attending to the precipitating-vats and the gantry crane, and two general laborers to assist in handling the iron and in loading the precipitate. With a smaller production of copper, but with the same quantity of solution being treated, the labor required would be proportionally less.

The consumption of iron rises above the theoretical because (1) of the iron-consuming elements in the solution other than that of the compound containing copper; (2) because of the oxidation of the iron when it is ex-

posed during washing or cleaning; (3) because of the removal of the fine scale on the iron when it is being cleaned by scrubbing or by washing with a strong force of water; (4) because of the oxidation of some element in the solution and its reduction by the iron precipitant while the solution is still under treatment for the recovery of its copper.

The first cause is, to a certain extent, fixed and uncontrollable. The second results in a heavy consumption of iron in the plain-vat system or in the launder system, but is largely overcome in the Irving-Dorr system by the adoption of agitation to free the precipitate from the iron; the loss due to fine scale is also almost entirely avoided, for although the agitation is sufficient to free the copper, it is not violent enough to remove the small iron scale. The oxidation of some element in the solution and its subsequent reduction by the iron is the cause of a large proportion of the consumption of precipitant. The oxidation of ferrous sulphate to ferric sulphate and its reduction by the iron to ferrous sulphate is common; it is due to exposure of the solution and the iron to the atmosphere. It is, of course, dependent upon the amount of solution exposed and the conditions under which it is exposed. Agitation by which air is absorbed by the solution is especially effective; this occurs to some extent in the downtakes of a launder system. It is also marked in the case where violent agitation and alternating exposure of the iron and solution is adopted to facilitate precipitation. In the Irving-Dorr vat this oxidation is almost entirely avoided; there is a large volume of solution in the apparatus of which only a small surface is exposed. The amount of agitation required is small; the solution reaches the surface in the form of a swiftly-moving stream; the surface exposure of the solution is only slightly increased by the agitation.

The tests showed that the finer the precipitant the greater will be the iron consumption, other conditions being the same. Small machine shavings of a metal will show a higher iron consumption than would be the case if one large piece were used. It was also found that different metals have different precipitating efficiencies; their ratio of iron consumed to copper recovered will vary. Further, the percentage and grade of coarse precipitate to fine precipitate depends on the class of precipitant used; the grade of precipitate varies with the ratio of coarse to fine, the material with the highest amount of coarse being the richest in copper. The coarseness and the grade of the precipitate also varies with the particle size of the precipitant used; large pieces of a metal gave a coarser and higher-grade precipitate than would result from the use of machine shavings of the same metal.

Hydraulic classification was used to determine the ratio of coarse to fine in the precipitate, the portion that settled readily in a dilute pulp being designated coarse. Thus it is possible to determine approximately what portion of the precipitate will be separated in the classifiers and what portion will go to the thickeners. The coarser the precipitate the cheaper will be the recovery and han-

dling costs at the precipitating plant, and the smaller the losses from transportation. The subsequent smelting and handling costs will also be less and the losses from dust will be smaller. It follows, therefore, that the coarse product is the more desirable.

The following table of results show clearly the different precipitating efficiency of the metals tested, their ratio of iron consumed, percentage of copper in the precipitate, and the ratio of coarse to fine precipitate, with a solution containing Cu, 2.4%; FeSO₄, 2.8%; Fe(SO₄)₃, 0.3%; Al₂O₃, 1.6%:

Precipitant	Ratio by weight of iron con- sumed to copper	Ratio of coarse to fine	Precipitate, % Cu
	precipitated		
Pig-iron	1.35 : 1	98 : 2	94.4
Wrought-iron	1.6 : 1	94 : 6	87.2
Cast-iron	1.65 : 1	93.5 : 6	86.8
Steel shavings. . . .	2.10 : 1	86.5 : 13	72.7
Cast-steel	1.75 : 1	94.1 : 6	80.1
Tin cans	2.35 : 1	81 : 19	66.9

The tests prove that the grade of precipitate varies approximately with the amount of iron consumed. The ratio of coarse to fine in the precipitate also varies in the same manner: the greater the proportion of coarse, the higher the grade of the precipitate. Although the quantity of slime produced is governed largely by the character of the solution, agitation will result in increasing the amount. In tests where violent agitation was adopted to facilitate precipitation, the precipitate produced was in a very finely divided state, and the ratio of slime was excessive.

The use of scrap-iron for precipitation, both for the recovery of copper from mine solutions and as an adjunct to metallurgical processes is increasing; it is apparent that a more satisfactory and dependable supply of such a precipitant must, in the near future, be available. A source which would be supplemented by the small amount of general scrap, such as is used at present and will always be procurable around the plants and small towns where precipitation is practised, would be the most desirable. Pig-iron, because of low precipitant consumption, high grade and coarse condition of precipitate, is the most economical.

The use of a small cupola furnace at an adjacent smelter, in which calcines, heavy in iron, could be smelted for the production of pig-iron, would offer a satisfactory solution of the problem. It would not be necessary to produce a high grade of pig, or to separate the copper or fine metals in the calcines, as these would ultimately be recovered. The cost of producing this pig-iron should be low, and, even on a small scale but under the conditions that should prevail in normal times, should not exceed \$15 per ton.

There is no doubt that methods will be developed that will supplant iron as a precipitant in some cases; but in view of past developments it is also probable that its general use will increase rather than decrease, because of the perfection of new methods and processes. The Dorr vat, and the method of precipitation described, do not con-

stitute a panacea for all the ills attendant on the precipitation of copper from solutions by scrap-iron. The results of a large number of tests, however, show that success has resulted from an effort to adapt mechanical methods to what has been a sloppy and messy operation, and one in which the labor requirements have been excessive. During both the development of the idea and its practical operation every effort was made to avoid new and untried methods and to refrain from any radical departure from well-known and accepted principles; the results are such that there is no necessity for costly experiments before the apparatus and method can be adopted elsewhere.

With the strengthening of diplomatic and commercial ties between the United States and Venezuela, the improvement of the existing railroads of the latter country and the building of new lines are brought definitely nearer. There are at present twelve railroad systems in Venezuela, with a combined length of 600 miles, and \$40,000,000 of invested capital. In addition, the building of four new railroads is being considered. One of these would connect the cacao region with the coast, the second would run through cattle, coffee, cacao, and tobacco lands, the third would bring the product of the country's oilfields to a deep-water port, and the fourth would make it possible to ship machinery to the Yuruari gold mines, which are now being worked only in a primitive way, and at the same time would tap grazing lands and iron-ore deposits. American capital is welcomed in Venezuela by the Government, which is pursuing a liberal policy toward foreigners. Recent laws guarantee railroad builders against the construction of rival lines paralleling their routes, and against oppressive taxes. Railroads are assured of a fair proportion of unclaimed lands, of the right to erect telegraph and telephone lines, and of the exemption of their employees from military service except in the case of international war.

The following table shows the amounts of lead and zinc pigments marketed in the United States in 1920, with the value and average selling price of each, compiled from reports made by producers to the U. S. Geological Survey.

As compared with 1919, an increase in the quantity sold was shown by every product except zinc oxide, in which there was a loss of 15%, but the average price per ton of zinc oxide showed a slight gain. There was also an increase in the average selling price of the other pigments. The greatest gains in 1920 were made by litharge, in which the gain in sales was 33% and the gain in average price per ton was \$61.11, or 44%.

Lead and zinc pigments marketed in the United States in 1920:

White lead:	Quantity (short tons)	Value	
		Total	Per ton
Dry	33,678	\$6,351,798	\$188.00
In oil	112,017	25,986,100	231.98
Red lead and orange mineral. . . .	31,431	7,523,089	218.50
Litharge	62,329	12,386,185	198.72
Zinc oxide	99,444	17,859,736	179.60
Lead-zinc oxide	30,100	4,467,532	148.67

Status of the Metal Mining Industry: An Interrogatory

The business department of the 'Mining and Scientific Press' recently issued an interrogatory to a number of engineers specially qualified to testify on the subject. This is the second part of the replies; the first appeared last week; the last will appear next week.

COPPER

Question 1: When do you expect a general re-opening of the copper mines? Please name approximate date.

"I believe that the mines that can produce copper refined f.o.b. New York for 10c. will start up before the middle of next year."

"It is impossible to guess at the date for re-opening of the copper mines, since this depends entirely on general conditions in this country and Europe."

"Personally, I don't expect a general re-opening of the copper mines before July 1, 1922."

"I anticipate that there will be no common date on which there will be a general re-opening of the copper mines of this country. Two very important factors will govern, one being the stocks of marketable copper on hand and the other the relative cost of production. These vary for every producing company of the United States, and will obviously control in each instance the date of their resumption of productive operations. As it requires approximately ninety days for transportation from Western smelters and for the refining, it follows that production will necessarily have to commence when the producer's stock of marketable copper is reduced to what he may estimate as his prospective sales for the coming three months. As regards the price of copper, even with the present surplus reduced to a basis of three months production, the estimated selling price must necessarily be the controlling factor in each instance. It is obvious that the mine whose copper costs 15c. to produce will not be inclined, even if its surplus stock is practically exhausted, to re-open on a 13 or 14-cent market."

"In about six months mines should begin to resume operations."

"I have no opinion to express relative to the re-opening of the copper mines, as this will depend entirely upon the condition of the copper market, which in turn is dependent, in my judgment, largely upon conditions abroad and the resumption of business activity in this country."

"The sales of copper in the past few months have been most unsatisfactory. When we closed down in April, I had hoped that we would start up in November. I cannot see now how we can start up before the first of the year, and I believe if we start up then it will be because of the crying need to give employment. I am of the opinion that we could remain closed down otherwise to good advantage until well on into the spring."

"It is idle to try to fix a date for the general re-opening of the mines. I can see no possibility of its happening before March first and it will probably be much later."

"I know of no method whereby the date of the general re-opening of the copper mines can be determined. There are altogether too many variables mixed in this situation, and as far as I know there is no precedent upon which to base any forecast. The copper industry is simply dependent upon the general resumption of business activities in this country and in Europe, and it appears that some time within the next year this activity should manifest itself."

"It is my opinion that this will not occur until after the end of the current year. I believe operations will be resumed to some extent about the end of the first quarter of 1922. The scope of such resumption, as compared with capacity, is something about which I believe no one can more than guess, but I may say, in a general way, that I do not expect that production will be warranted generally to more than somewhere between 50 and 75% of normal capacity for at least twelve months following the date of partial resumption."

"I do not think that even an approximate date can be set for a general re-opening for the copper mines. It depends upon the rapidity with which the metal market improves and this in turn is dependent upon the recovery of industry generally from its present extremely depressed condition."

"I have no opinion on this point."

Question 2: Are the managers of existing properties taking advantage of the opportunity afforded by the shut-down to consider ways and means of reducing operating costs through the introduction of more modern and more economical equipment? Please give such particulars as you can.

"The managements of many of the mines in this State are indifferent. We are centring all our endeavors to

get the cost of the running of the State of Arizona reduced for the year 1922 to one-third of the cost of last year, and of securing a 54c. rate on oil from Oklahoma and Texas to —, a \$5 rate on bullion from — to San Pedro, and a reduction in the rates on mine timbers from sawmill points in Arizona and San Pedro to —.

"The people of the State of Arizona have gone wild on extravagance. The appropriations passed by the last legislature for State government alone exceeded the appropriations of the former legislature by a million and a third of dollars. Road bonds have been issued and sold and are returnable as to principal and interest, and the total cost of running the State, municipal, and county governments for the year 1921 will exceed thirteen million dollars. The per capita cost for the United States government is something over \$6. The per capita cost of Arizona is \$24. Hence, the necessity of the mining companies and of others who so largely in this State depend upon the mines for a living centring on the reduction of the present extravagant habits in order that copper may be mined, reduced, refined, and sold at New York for 10c. Several of the mines in this State can reach this figure if they make up their minds to it."

"Managers of existing properties are generally considering methods of reducing operating costs through introduction of more modern and more economical equipment, but the financial condition of the companies makes it impossible to make such improvements at present."

"The managers are taking advantage of the opportunity afforded by the shut-down to make improvements looking to a reduction of operating costs.

"The — Copper Co. is preparing to sink a new shaft and equip the same. They are also busy with plans for a large leaching-plant to handle their oxide ores. They are making other improvements of minor character tending to reduce costs. You doubtless have received information about this direct from company headquarters.

"The — Copper Co. contemplates changes in its mechanical equipment, including rehabilitation of the crushing and concentrating plant, the addition of a bedding system for reverberatory fines at the smelter, and the addition of high-pressure boilers in the power-plant, the total to cost around \$500,000, with possible economies that would return the money in two years operation."

"Believe majority of mine managers and metallurgists are considering methods of reducing operating costs and improving recoveries. Believe study is being made of systems of mining for the purpose of determining which is best applicable in each particular property, and in the case of metallurgy, understand new flotation agents will result in better recoveries and that improvements in flow-sheet will reduce costs."

"The managers of all properties, I believe, are at all times considering ways and means of reducing operating costs, through the introduction of more modern and more

economical equipment, as has been evidenced in concentration by the almost universal adoption of the flotation process."

"To some extent. Managers are always considering ways and means for reducing costs. At some of the older plants capital expenditures are being made, or are about to be made, to decrease costs. This is notably true at Bisbee, Cananea, and Nacozari.

"The Clifton district also faces heavy capital expenditures for milling the great tonnages of lean ore that have been opened up in recent years.

"All these improvements are not so much made because of the close-down as because plants have become gradually worn out, or because conditions have changed, or both. Recent advances in mining and metallurgical methods have converted large tonnages of copper-bearing rock into marginal material. Those mines that have this material are in some cases preparing to utilize it."

"The managers are considering the reduction of costs by the introduction of more modern and economical equipment, but it is doubtful whether their stockholders will consent to any large construction campaign at the present. It is always much more difficult to secure appropriations for such work in dull periods and in most cases the changes made will probably be of minor importance. So far I have heard of no decisions to make large improvements."

"I do not know that any of the copper producers are making any more effort at this particular time to reduce operating costs than they have in the past, for all progressive managers certainly have this point in mind at all times. There are some plants that I know of that are making improvements that could not be made while operating, and to that extent these particular properties are obtaining a benefit through the shut-down because they are able to make improvements that otherwise could not have been made without loss of output."

"At the properties operated under my direction such activities are being continued in a limited way and with respect only to details of improvements, affecting the metallurgical facilities principally, which were under way at the time of suspension."

"I am of the opinion that most of our producers are taking advantage of the shut-down to prosecute development work and preparation for extracting their orebodies economically, as well as modifying their mill flow-sheets, and, in some cases, increasing the capacity of their concentrators and their smelting plants."

"In the case of the — Co., regarding which only I can speak with authority, not only has active development taken place in the limestone mines of the — Co., but the disseminated deposits are being stripped of their overburden and put in shape for production early in

1922. There is also nearing completion a 4000-ton concentrator in order to treat these disseminated ores. At the — Copper Co., the flow-sheet of the mill is being changed and provision made for increasing the tonnage from two to three thousand tons, while extensive improvements are being installed at the mines in order to reduce the cost of producing ore."

"I do not think that much new equipment is being installed. In our own case we have endeavored to keep our equipment up to date, and I do not know of any changes we can make which would yield any material additional economy. I think this has been the policy of practically all of the prominent producers. However, even if there were items of equipment that I would like to install it would not be done now, since prices of machinery and equipment generally have not dropped as much as they should and I think can be purchased for less money later on."

"My experience is that managers of copper properties are continually endeavoring to reduce operating costs. As a whole, copper mining is a fairly efficient industry and it is not expected that any sudden improvements can be made. It is a slow growth and development."

Question 3: What steps are being taken, if any, by the copper producers toward the inauguration of a campaign to increase the use of copper in the arts and crafts?

"The Copper Research Association."

"The newspapers are announcing the formation of a copper and brass research institute for the promotion of the use of copper."

"I know little of activities of the copper producers toward the inauguration of an advertising campaign to increase the use of copper in the arts and crafts. However, the — Copper Co., through — efforts, is experimenting with methods for manufacturing copper articles direct from solutions produced in their leaching process.

"A few decades ago the builder had shingles, slate, terne plate, or copper to select his roofing material from. Since then asphaltum and coal-tar products have been developed and applied. It is a process of evolution. There is no more reason to go back to the copper roof as of old than to go back to the flag-stone sidewalk. If there is any place where a copper roof is justified I think a copper smelter should have it, but there are none in existence (except some experiments). There is no more copper in the world than is required in its perfectly legitimate field of usefulness. It is indispensable in industry and the trouble is mostly with industry. It would be a waste of metal to use it more universally just to create a market for it. The public should not be asked to 'buy something made of copper'. Copper is

not a mendicant among metals. It doesn't appeal for public alms, but the public might profit by becoming better acquainted with its many virtues, and these might be advertised."

"Have recently noted formation of the Copper and Brass Research Association, which is composed of the principal copper producers in the country. I understand the object of this research corporation is to find new uses for copper."

"Both copper producers and consumers are very active in inaugurating a campaign to increase the uses of copper in the arts and crafts, through the Copper and Brass Research Association, which has recently been formed, and with which you are doubtless familiar."

"I am not as well posted on this subject as they are on the selling end. I believe, however, that the producer cannot permit the fabricator to pursue old-fashioned methods of manufacture and salesmanship and at the same time use his, the producer's, stockpile as a warehouse to draw from as convenient. The producer's stock might just as well be fabricated and on a hardware shelf or in a plumber's shop as lying idle in a stock pile, and if the former were the case the producer would automatically have a great increase in the number of interested salesmen. I am inclined to think the producer may be forced to become a fabricator, using modern methods and modern machinery and seeing to it that his wares come direct to the consumer and that their value is impressed upon the consumer."

"The producers are forming a Copper Research Association to promote the use of copper but the high prices charged for copper and brass products still hampers the sale of them to the general public. Ultimately some of the large producers will be compelled to go into the fabrication of copper and brass products to stabilize the copper market but aside from what has been done by Anaconda, I do not know of any decision to do this now."

"The producers and consumers of copper are making every effort to foster a campaign which would popularize the use of copper in the arts and crafts. So far this effort has crystallized in the organization of a copper and brass research committee with headquarters in New York, and with this as a nucleus I presume larger things will develop."

"Active steps of this nature are being taken through the Copper and Brass Research Association, recently organized."

"The copper producers, together with a certain number of the important fabricators, have joined in a voluntary association, entitled 'The Copper & Brass Research Association', to investigate the uses of copper and its alloys

and to educate the public to the merits of the metal. It is expected that ultimately, after certain research work has been concluded, a campaign of publicity and advertising will be inaugurated, and it is hoped that the consumption of copper per capita in this country can be greatly increased."

"The Copper and Brass Research Association, announcement of whose formation was recently made, has for its object stimulation by co-operative effort of the use of copper, brass, and copper-alloy products."

"The copper producers, in conjunction with the brass people, have, as you probably know, organized a Copper and Brass Research Association, of which W. S. Eckert is the secretary, his address being Room 1903, 25 Broadway, New York. The object of this Association is, by advertising and other legitimate means, to increase the use of copper and brass and to combat propaganda which may be issued by the producers of other metals seeking to replace copper."

Question 4: What class of mining, milling, and smelting machinery is least satisfactory in the performance of its function, and in what respects should it be improved?

"Mechanical equipments are as up to date as in any other industry in the country and much saving in the reduction of labor is not easy to readily see."

"The mining machinery which is least satisfactory is the mucking machinery. A mucking machine which will handle both fine and coarse material without excessive repairs has not as yet been developed. The milling machinery which is least satisfactory is the intermediate crushing machinery between gyratories and roller or ball mills. The existing intermediate crushing machines give excessive repair costs on hard ores. The most unsatisfactory smelting machinery is that for the collection of fine dust without excessive cost for reduction of velocity and temperature of gases, and the machinery for treatment of fine dust."

"There is still room for improvement in the machinery used for crushing ore, particularly in screening between stages."

"The industry also awaits the man who can develop a greatly improved method of removing water from flotation concentrates. The best the present vacuum apparatus can do is to make a putty-like mass which is most difficult to handle. The use of heat in reducing the moisture thereby making the product satisfactory to handle is ordinarily too expensive. In most flotation plants the settling and filtering apparatus requires greater area and nearly as much attention as the rest of the mill, and the 'tail will continue to wag the dog' until somebody makes a big improvement in the filtering end of the business."

"Am unable to state what class of mining, milling, and smelting machinery is least efficient, but there is probably room for improvement in all."

"I do not think that I could concentrate upon any particular form of machinery that requires improvement."

"Mining, milling, and smelting machinery are keeping up with progress pretty well. The Smith-Pierce converter is passing the upright converter in efficiency partly because of less mechanical loss. Mechanical loss generally needs further study, especially in the older plants. The utilization of streams for power and its transmission will be badly needed as the supply of fuel oil decreases, and I believe other substitutes will have to be provided for fuel oil as a smelting fuel or new processes devised."

"A subject that worries me more than machinery and smelting methods is a proper treatment for lean, mixed sulphide and oxidized copper ores. Lean ores have necessarily far narrower margins and dual processes are objectionable. It is simply a case of increased costs to be more than counterbalanced by increased recovery."

"Progress has been made in the treatment of thoroughly oxidized ores by wet methods. I am inclined to believe that there is a broad field and an urgent need of a study of wet methods as applied to these mixed ores."

"Your fourth question covers a rather large field but I would call attention to the fact that the pump manufacturers of this country have so far failed to perfect the centrifugal pump to anything like the extent that this has been done in Europe. The small space required and the small amount of attention necessary give this pump a very decided advantage over the reciprocating type for mine use but its low efficiency makes the cost of operation prohibitive in large installations."

"This is a very difficult question to answer without going into a complete detailed discussion of each operation, which I presume was not the object of your inquiry."

"It is my opinion that for a long time screening or sizing apparatus, and particularly that designed for fine screening or sizing, has been the outstanding class of least satisfactory apparatus in mining and metallurgical industries. It may be said, however, that in recent times the necessity for fine and accurate sizing has decreased very markedly, and especially so as pertaining to wet sizing, this having come about through the extending use of flotation processes."

"This is a difficult question to answer, as it varies with each particular class of ore, and each individual producer has his separate and distinct problems."

"The selection of mining, milling, and smelting machinery is governed by the character of the ore deposit to

be mined or character of the ore to be milled and smelted. I think that satisfactory machinery is available for almost any operations and cannot think of any one class that is at present unsatisfactory. An improvement in stoping drills would be the development of a satisfactory drill with water feed to keep down the dust."

"It is impossible to give any answer to this question because there are few managers who are employing machinery which they think is unsatisfactory. Of course in certain cases as the art advances improved machinery is not always put in immediately, as it is more economical to wear out the old. In the new crushing plant of the — Copper Co., which we have just started at No. 5 shaft, we have so laid out the work that we have been able to eliminate bucket elevators and replace them by gently inclined belt-conveyors. We have also eliminated trommels and replaced them by new types of vibratory screens, one section being equipped with Mitchell screens and the other with Hummer screens."

Question 5: 'Is there a tendency to substitute mechanical for hand labor wherever possible, and for what particular class of work?'

"Mechanical devices are being substituted for hand labor wherever possible; especially in the handling of ore."

"There is a tendency in the United States to substitute mechanical for hand labor wherever possible. In Mexico there is more of this than before but less than in the United States. The big mining companies are continually improving their mining methods and are experimenting with mucking machines, etc. They are quick to take up any mechanical device that will lessen costs."

"All mine managers have always been striving for means for reducing hand labor and since the time of great increase in rates of wages and loss of efficiency by laborers, additional efforts have been made to reduce to a minimum all hand labor."

"There is always a tendency to substitute mechanical for hand labor, especially in handling rock underground, and I think that nearly all of the large mining companies have been endeavoring to get mechanical shovelers, but thus far few of those invented stand the wear and tear of underground work, and on account of limited space underground in narrow drifts, it is impossible to use the mechanical shovelers of greater strength."

"There have been few radical changes in process, but these stand out like beacons in the metallurgy of copper. The most notable are the introduction of the converter, the introduction of flotation, and the beginning of wet methods of extraction of copper from oxidized ores with the production of refined copper. During the past 20 years there has been a tremendous advance in increasing

the size of units and decreasing the cost of handling materials through the introduction of mechanical methods, and this tendency continues and always will continue.

"It was easy to introduce cheaper methods of handling material in metallurgy because metallurgical processes are conducted on the earth's surface. It was much more difficult to introduce mechanical methods underground, but with changes of mining methods and increase in the size of units, together with mechanical traction, great improvements have been and are being made underground with a tremendous increase in the tons produced per man per shift. There is still room for great development in this direction."

"There is a strong tendency to substitute mechanical for hand labor, notably in shoveling. The mechanical shovels I have had experience with give encouraging results but are still in an experimental stage and will have to be greatly improved in design. Power haulage has already supplanted hand tramming to a very large extent but there remains much to be done in the development of satisfactory cars and unloading devices."

"Yes, for every class of work without exception."

"I think there is a universal effort being made to substitute mechanical for hand labor wherever possible, not only in the mining of ores but in the subsequent handling at concentrators and smelters."

"It has been for some time past the policy of many companies to substitute mechanical means for performing work wherever it can be done economically. One operation which is receiving considerable attention at present is mechanical mucking. As over half of the underground labor in deep mines is employed in handling the rock after it is broken, there would seem to be an important field here for developing mechanical contrivances to do the work."

"The whole tendency in modern mining, concentrating, and smelting is to substitute mechanical for hand work wherever possible. In mining the porphyries, the general tendency is toward some caving or shrinkage system in which the ore runs down into chutes and from there loaded into electrically operated cars. In certain methods an intermediate tramming with the use of hand cars is resorted to, but the haul is not long. In the Lake Superior copper mines, particularly those having a flat dip, there is a tendency to introduce mechanically operated scrapers which pull the ore, or 'rock', as it is locally called, down the stopes onto a shelf or platform, from which it is pushed into the cars. In the Lake Superior copper mines hand-tramming is gradually giving way to tramming with electric locomotives, some being operated by trolleys and others by storage batteries. This results in the cutting down of the number of shafts necessary to exploit a piece of ground, as when hand-tramming was used it could not be extended over

long distances, and hence the shafts had to be close together."

SILVER

Question 1: Is silver mining recovering by reason of the general lowering of the cost of production?

"Yes."

Question 2: Is the operation of the Pittman Act a sufficient incentive toward increased interest in prospecting for and development of new silver properties?

"Yes."

Question 3: Is the present lull in the production of copper stimulating the operation of silver mines by reason of the cessation in the production of by-product silver?

"No."

Question 4: Are the managers of existing properties considering ways and means of reducing operating cost through the installation of more modern and more economical equipment?

"Yes."

Question 5: If the answer to No. 4 is 'Yes', please give such particulars as you can.

"UNDERGROUND. The use of better drilling machines. The use wherever possible of mechanical shoveling. Substitution in part of 'hand tramping' by electric motor haulage.

"MINE-SURFACE. Greater use of machine drill sharpeners."

Question 6: What class of mining and milling machinery is least satisfactory in the performance of its function, and in what respect should it be improved?

"This is too broad a question to answer by a letter of this nature."

Question 7: Is there a tendency to substitute mechanical for hand labor wherever possible, and for what particular class of work?

"Yes: mucking and tramping."

(To be Concluded.)

A BRITISH aluminum company, in a brochure which it has issued dealing with the use of aluminum for bus bars and inter-connections in electric-power stations, claims that aluminum offers a more complete economy than the substitution of bare copper rod or bar for insulated cable, states a consular report. It claims that the use of aluminum results in considerably reduced initial costs, greater ease in erection, smaller temperature rise for equal inductance, and less weight; also slower temperature rise under temporary heavy increases of load and greater resistance to corrosion. The company urges that on the

basis of conductivity, an aluminum conductor of the same resistance and length as one of copper will have a cross-sectional area greater in the ratio of 10 to 6, whereas the weights will be roughly as 1 to 2. With heavy currents an aluminum bar, because of its greater perimeter, will have considerably lower temperature rise than a copper bar. When prices of the two metals are such that for equal resistance aluminum shows a cost saving of 15%, the equivalent cost saving with heavy-current conductors will be from 25% to 30%.

Diamond Industry

A new impetus is manifest in the diamond market of Antwerp, which is one of the most important in the world, and certainly the most important in diamond cutting, states a consular report. This impetus, due to a sort of willingness to trade at any price, is local, reports from other centres being still less favorable. At the same time, the big merchants and dealers are optimistic and unanimous in predicting a general resumption of activity. For about two months the supply of diamonds from Russia had apparently ceased, when suddenly a parcel of several thousand carats was again negotiated on the market. A considerable portion of this lot had to be re-cut. Besides these Russian stocks, the importance of which has been overestimated, the market seems to have been further unfavorably influenced by contraband and smuggling, which have been on the increase since the signing of the Armistice. It is thought by some merchants that the Government could intervene to advantage by placing on stones presented for re-cutting a duty of, say, 20%. Such a measure, however, besides being difficult of application, would be inoperative unless adopted by all countries. The measure taken in one country only would result in favoring cutting establishments in neighboring countries. Antwerp would then remain exposed to the disagreeable duty of smuggling so long as the situation did not improve in Russia and Poland, where persons in need of funds sell their jewels at low prices. At present, therefore, it is difficult to give the carat a correct value.

In South Africa, after the monthly output had reached 9424½ carats, valued at 1,925,000 francs, the lowest registered since the crisis of 1907, the exportation of diamonds has apparently taken an upward turn. A notable event during the months of the crisis was the discovery of a 381-carat stone at Gong-Gong. The story of this find is to the effect that three men obtained a concession in the new bearings of Mosesberg. Arrived at Barkley West, they unhitched and their mules strayed off. Not being able to continue their journey the men determined to try their luck on the spot, and it so happened that they found on an abandoned concession this 381-carat diamond, the greatest discovered on the river.

The carat, which was worth £17 4s. (\$83.59 at normal exchange) at the beginning of the year, has dropped to £10 7s.3d., reaching, it seems, its lowest level. In June a real advance was shown, 12,322 carats being exported, representing a value of about 3,000,000 francs.

Scheduling Mine-Operations to Suit a Power-Contract

By B. B. Beckett

***INTRODUCTION.** The title of this paper is a little too broad in that the term 'metallurgical plant' should be restricted to the ordinary mill found in connection with mining enterprises in the West. It should not include such plants as iron and steel mills, electro-chemical plants, smelters, or copper refineries. My experience has been chiefly in gold and silver mining, particularly at Goldfield, Nevada.

Most power-contracts or rate-schedules for mining companies contain some sort of load-factor provision. These vary widely; they are sometimes illogical; and it may be that a better understanding on the part of power companies as to what mining companies can economically do in the matter of controlling their load-factor will result in more reasonable provisions in the contracts.

CHARACTERISTICS OF 'MINE-LOADS'. The load-factor of mining enterprises is high even without any effort to make it so. A mill-load is nearly constant for 24 hours per day and for about 363 days in a year. A mine-load, considered separately from the mill, is not so good, but still much higher than most industrial loads. When the two are combined, as is usual, the resultant load-factor is very high, since the mill-load will predominate, being usually three or four times as great as the mine-load, measured in kilowatt-hours. The load-factor of a mine and mill, based upon the maximum 30-min. kilowatt-hour demand per month will be about 70% even if no control is exercised, and may be made as high as 90% by careful scheduling of operations.

The one difficulty with mine-loads is the induction-motor hoist generally used. Hoists cause violent load-fluctuations of short duration, but do not materially affect the load-factor as based upon a maximum demand for 30 min., or even for 5 min.; and the objection to them lies in the voltage-disturbances which they set up rather than in the relation of average load to the maximum load that the generating and transmission equipment will carry. These voltage-disturbances are often severe and it is usually sought to restrict them by provisions in the power-contract, sometimes by 'demand-charge' or other load-factor provision based upon a peak of short duration—one minute or less. This is not strictly a question of load-factor and does not come within the scope of this paper, as it cannot be controlled by scheduling operations, but only by some provision for storing energy such as a fly-wheel, storage-battery, or compressed-air storage. It is mentioned here because it is closely allied to the subject of the paper and the two are sometimes confused. In my opinion the matter of voltage-disturbance should

be kept separate from load-factor; it may be guarded against by a simple provision in the contract prohibiting the use of any motor above a certain size without providing some means for absorbing the starting currents. The matter of load-factor can then be satisfactorily treated on the basis of a 30-min. maximum-demand interval.

In a similar way, mention is made here of another load characteristic which is closely allied with the subject of this paper, namely, power-factor. The power-factor of mine-loads is usually good, for, although induction motors are used almost exclusively and many of them are lightly loaded, the bulk of the load will always be on large motors, well loaded. If all motors are of the induction type, and the transformer and feeder layout is properly designed, the power-factor will be about 85%. This can be increased readily by the use of synchronous motors, particularly for large air-compressors; in fact, air-compressors of the direct-connected type are often driven by synchronous motors even when no inducement is made in the power-contract. In most plants in the West, due to the fact that transmission lines are long as compared with the load to be carried, the line-charging current will offset the lagging current represented by a power-factor of 85%, but for the sake of those plants where a higher power-factor may be desirable, the fact is noted here that a moderate inducement in the rate would doubtless bring about an increase in the power-factor of mine-loads.

POWER-CONSUMPTION OF VARIOUS OPERATIONS. It is well to have in mind the nature of the chief power-consuming operations about the mine and mill and the relative consumption of each. For a typical case, these data are shown in the following table.

Operation	Percentage of total kw hr	Percentage of aggregate demand (Max. 30 min.)
Mining:		
Compressing air	13	19
Hoisting and tramming	4	7
Pumping ..	4	9
Milling		
Crushing	2	4
Fine grinding	48	30
Concentrating	2	2
Cyaniding	21	17
General and miscellaneous	4	6
Total	100	100

This table is based upon operations at Goldfield, Nevada, from 1915 to 1918, but it is typical of gold and silver mining, and not very different from copper and other base-metal mining except that there would, of course, be no cyaniding. In some mines there is no water to pump, in others a great deal more. In a straight concentrating mill, where the only product is concentrate ready for shipment, the item for concentrating will be somewhat greater. In some oil-flotation plants the power will be around 8 or 10% of the total. In any case, the large item will always be fine grinding, that is, the opera-

*A paper presented at the meeting of the San Francisco section, American Institute of Electrical Engineers, September 23, 1921.

tion of reducing the ore from $1\frac{1}{2}$ - or 1-in. pieces to slime. Grinding, concentrating, and cyaniding are continuous operations and have a load-factor of nearly 100% except for variations in the supply of ore.

Crushing is sometimes continuous but more often a one- or two-shift operation and always makes a greatly fluctuating load. These fluctuations will not appear, however, in a 30-min. peak-demand. Crushing can be readily scheduled to suit the load; that is, it can be done at a time of day when the load from other sources is least heavy.

Mining proper cannot be scheduled to suit the load. It must be done to suit the men, for the simple reason that the payroll far outweighs the cost of power. For instance, a production of 1000 tons per day will require, say, 500 men receiving \$2500 per day and will consume some 7500 kw-hr. costing \$100. Mining is usually carried on in two shifts except where the work is to be rushed and the working space is limited, as, for instance, in shaft-sinking. It has an inherent maximum load-factor, therefore of 67%, and is usually about 50%. This covers air-compressing, hoisting, and tramming.

Pumping from mines may usually be scheduled to suit the power-contract, but this is sometimes prevented by lack of sump-capacity to hold the water between pumping periods.

ECONOMICS OF LOAD-SCHEDULING. If no inducement is offered in the power-contract and no restriction made, the only load on the third or 'graveyard' shift will be that of the 24-hr. operations. Crushing and pumping will be done at the same time as mining, and since the shops, saw-mill, assay-plant, and other general and miscellaneous items will be day-loads and will outweigh the evening load for lighting, the peak will come in the day time, usually in the forenoon; moreover the peaks of the several loads will be simultaneous.

How far it will pay the company to go, in scheduling for the graveyard shift some of the normal day-load, will, of course, depend on the inducement offered in the power-contract. This may vary all the way from nothing, as on a straight meter-rate, up to that obtained on a flat-rate charge of, say, \$10 per horse-power per month. Neither of these extremes will result in the maximum economy for both parties, and the modern method is a two-part rate, or a sliding-scale meter-rate depending upon 'hours use', or upon some other load-factor provision.

The two operations that can readily be scheduled are crushing and pumping. Crushing is a small item. Even when confined to one or two shifts, as is usual, the crusher-load for a 1000-ton mill is only about 80 kw., based on 30-min. maximum demand; and if the load-factor in the rate is equivalent to a demand-charge of, say, \$1 per kilowatt per month, the resultant saving by keeping this load off the peak will barely justify the hardship upon the crusher-men, arising from being required to work always on the graveyard shift. But if the demand charge is, say, \$4 per kilowatt per month, then the saving, \$3840 per year, will justify additional investment for larger bins and a larger crusher, if that should be necessary in any particular plant.

Pumping from the mine, pumping water for use in the mill, and pumping fresh water for general purposes, may all be scheduled as desired provided there is sufficient storage-capacity. This is usually ample in regard to fresh water and water for mill use, so that no extra expense is involved; there is frequently no inconvenience to men, because the pumps are run without attendance. The problem of storage underground is more difficult. If the lift is great and the demand-charge rate also high, it will usually pay to create the necessary sump so that the pumping may be done entirely 'off-peak', even though this means the driving of long drifts for this purpose alone. Sometimes an old drift or stope is available as a sump and sometimes a reservoir can be bulkheaded in workings that are not in use. If necessary to create a sump, the cost will have to be figured against the saving that may be made. For instance, suppose the flow is 200 g.p.m., the lift is 1500 ft., and a demand-charge is \$4 per kilowatt per month. This would require about 80 kw. for 20 hours per day. For this the demand charge would be \$3840 per year. If pumping is to be confined to the graveyard shift, additional capacity of 12-hr. inflow, or 19,200 cu. ft., equivalent to a drift 8 by 8 by 300 ft. would be required, which would cost about the equivalent of one year's power saving, or \$3840. Some additional pumping equipment will be required, also, but not much, for at least two pumps, one as a spare, are necessary for the 20-hour schedule, while for an 8-hour schedule it would be safe to operate both at once without providing a spare.

As regards the pump-men, no attendance is required for turbine-pumps and these, in fact, may be made automatic and 'remote-controlled' so that they can be started and stopped from the office on the surface. They can be thrown on at noon or at other times during the day whenever the load permits.

There is one other operation in which load-scheduling may be advantageous in some cases, namely, in fine-grinding in the mill. This is a 24-hour operation but the load can sometimes be lightened on day shift without loss of production, as when the mill is running ahead of the mine, or when the upper part of the mill is running ahead of the lower. This must be done with care as any interruption to the uniform flow through the mill may result in loss of extraction. The importance of this will be seen if it is remembered that, for instance, a 1000-ton mill on \$15 ore is handling a gross value of \$15,000 per day and, if the extraction is 90%, each 1% loss is \$165 per day. For this reason, and because of the heavy investment in this equipment, it will not usually pay to install additional grinding equipment for the purpose of scheduling loads; but, where the conditions already exist, and the demand-charge is high, advantage may be taken of the opportunity. This was done at Goldfield with a saving of about \$1000 per month, under a flat rate of \$6 per horse-power per month.

CONCLUSION. Mine-loads can be scheduled so as to produce a very high load-factor; the extent to which such scheduling is economical depends upon local conditions and upon the inducement offered in the power-contract.

REVIEW OF MINING

COPPER SHARES SHOW STRENGTH; REASON FOR OPTIMISM

Shares of the various copper-mining companies are in better demand at higher prices than for many months. While no one looks for a runaway advance, unless there should be a sudden demand on the part of domestic consumers to cover requirements for some time, tangible evidence points to a steady recovery in the industry. When copper stocks were depressed following the close of the War, estimates of huge amounts of metal all over the world were used to depress securities. At present just the opposite view prevails. While it is well-known that the available surplus is still in excess of normal requirements, the fact that current sales are twice as high as the monthly production has changed sentiment materially. The fact that most of the leading mines of the country are closed down, and further that it will be several months after resumption before copper comes on the market, adds strength to the market. The following table shows the 'low' for the year as compared with the recent 'high' and the advance:

	1921	Recent	
	low	high	Advance
Ahmeek	40	54½	14½
American Smelting & Refining	29½	39½	9½
Anaconda	31½	41½	9½
Calumet & Hecla	210	245	35
Chile	9	12½	3½
Chino	19½	26	6½
Copper Range	27	36½	9½
East Butte	7	10	3
Inspiration	29½	36½	6½
Isle Royale	16½	20	3½
Kennecott	16	22½	6½
Mohawk	43½	54	10½
North Butte	8	11½	3½
Old Dominion	15½	24	8½
Osceola	21	28½	7½
Quincy	33½	41	7½
Utah Copper	41½	52½	11½

JAPAN IS OUR BEST CUSTOMER FOR ZINC

If it were not for the small volume of pig- and slab-zinc moving out of this country to Japan since January 1920 the export trade in that metal would be small indeed. Japan was our best customer in August for the fifth consecutive month, exports to that country far exceeding those to any other.

In August 1,537,714 lb. of zinc in pigs, slabs, etc., was exported, and of that total 1,008,014 lb., or 65%, went to Japan. For the six months ended with August 1,905,748 lb. or 65% of our total export zinc trade during that period was with Japan. France and the United Kingdom were our best customers during the War and for several months thereafter. This year, however, not a pound has been exported to either of those two countries, whereas during the first eight months of 1920 France took 47,999,000 lb. and the United Kingdom 133,147,000 lb., so that it can be appreciated that the discontinuance of the export trade in that metal with

those two countries has proved a blow to the producers of this country. Our export trade in pigs, slabs, etc., for the eight months ended with August amounted to 3,195,896 lb. against 198,738,000 lb. during the corresponding period of 1920, and 169,379,000 lb. during the first eight months of 1919. Our export trade in zinc sheets, strips, etc., for the eight months this year amounted to 2,320,000 lb., against 19,461,000 lb. during the same period last year, and 28,543,000 lb. during the first eight months of 1919.

The following shows how important a factor Japan has been in our zinc export trade during recent months, the figures being in pounds:

	Total exports	To Japan	Proportion of total, %
August	1,537,714	1,008,014	65
July	429,503	280,024	65
June	537,328	393,730	73
May	135,365	112,000	83
April	115,838	111,980	97
March	174,106
Total	2,929,854	1,905,749	65

UTAH METAL OPERATORS INSTITUTE IS FORMED

A permanent organization to be known as the Utah Metal Operators Institute is the outcome of a highly successful series of meetings held at Salt Lake City last week. An annual conference will be a feature of the work of the Institute.

At the final session held on October 9 it was unanimously resolved that an executive committee should be created, this to consist of two representatives from the State's three leading districts, Bingham, Tintic, and Park City, to be selected by the delegates from these districts; two representatives from outlying districts to be approved W. Mont Perry, chairman, and one representative each from the Utah chapter of the American Mining Congress, from the American Institute of Mining and Metallurgy, and from the State Industrial Commission. This committee, to be organized in the near future, will have for its chief function the drawing up of plans for the next annual institute.

Following are the programs for the meetings just held: Friday, October 7, 9:30 o'clock—Keynote address, C. E. Allen, manager, U. S. Smelting, Refining & Mining Co., temporary chairman; address, Governor Mabey; paper, 'Requirements of Hoist-Signaling in Metal Mines', by Leonard Wilson; discussion led by T. P. Billings, O. N. Friendly, and W. H. Cole; papers, 'Improved Methods of Stopping Adaptable to Utah Mines', by A. S. Winther, general superintendent, Utah Consolidated Mining Co., J. R. Hafner, foreman, Tintic Standard Mining Co., and A. P. Mayberry, superintendent, Centennial Eureka mine; discussion led by Joseph Hyland, R. E. Phelan, and J. A. Norden.

Friday, October 7, 2 o'clock—Paper, 'The Field for the Storage-Battery Locomotive in the Mines of this State', E. A. Hamilton, superintendent, U. S. Mines, Bingham; discussion led by L. R. Dobbs and H. T. Plumb; paper, 'The Efforts of the American Mining Congress in Standardizing

Mining Machinery and Methods', by H. C. Goodrich, chief engineer, Utah Copper Co.; discussion led by Charles Zabriskie and E. H. Burdick.

Saturday, October 8, 9:30 o'clock—Paper, 'Our Experience in Overcoming Hot Mine Gases', by A. J. May, superintendent, Tintic Standard mine; discussion led by Lew Merriman and A. C. Nebeker; paper, 'The Present Status of the Wet Stopping Drill', by H. G. Snyder, Metal Mine Inspector; discussion led by William Owens and H. N. Hartman; paper, 'Should Metal Mine Operators of Utah Conduct Future Meetings of this Kind?' by L. S. Cates, manager, Utah Copper Co.; discussion led by E. F. Birch, A. G. MacKenzie, D. D. Muir, and J. Fred Johnson.

UTAH-APEX V. UTAH CONSOLIDATED

The decision of the Federal District Court handed down in Salt Lake City last October, favoring the Utah-Apex Mining Co. in litigation with the Utah Consolidated Co., left the latter corporation under obligation to file an accounting of the ore declared by the court to have been unlawfully extracted from the Utah-Apex property. According to the Utah Consolidated accounting, the sum due Utah-Apex in accordance with the decision of the court amounted to about \$650,000. Utah-Apex protested these figures and obtained an order of the court to permit the statement to be checked by an audit of Utah Consolidated books. The audit, it is claimed, revealed errors in the statements, and discrepancies between them and the books, which increased the amount due Utah-Apex to nearly \$1,500,000. The accounting hearing began in the trial court on August 22. Utah Consolidated admitted errors and discrepancies in their accounting, but maintained different charges objected to by the Utah-Apex. Utah Consolidated again applied for an extension of time, and the hearing did not take place until September 29, when the court took the case under advisement. While these proceedings were pending, the appeal of the Utah Consolidated against the decision of the trial court was heard in Denver on September 6, the court taking the case under advisement for subsequent decision.

SALES OF COPPER INCREASE

Sales of copper, both foreign and domestic, during September were approximately 100,000,000 lb. This is the largest monthly sale since last spring and compares with an average business of 75,000,000 lb. per month during July and August. Domestic sales showed more improvement than did foreign, most of the metal being sold during the last third of the month. Renewals of buying by brass interests helped greatly to increase the total.

Initial demand for 1922 copper has come to hand in an inquiry for 3,000,000 lb., to be delivered in installments of 1,000,000 lb. monthly during the first quarter. Producers thus far have refrained from opening their books for the coming year.

The Western Union Telegraph Co., which early this year bought a large quantity of copper, has re-entered the market for about 2,000,000 lb. Wire manufacturers have joined their inquiries with those of brass-mills, giving indication of a sharp improvement in demand from domestic consumers.

ACTIVITY OF THE A. S. & R. CO.

The Mexican operations of the American Smelting & Refining Co. are about the same as six months ago, as the rise in silver price has been too recent to have much influence as yet upon foreign ore-shipments. All the smelters of the company in Mexico, except the Asarco and the Monterrey plants, are in operation. The Pueblo plant is still shut-down as a result of the flood, while the Perth Amboy

refinery has been shut-down for several months, the copper refining being now done at Tacoma for Western ores and at the Baltimore works for Eastern receipts.

In Colorado the Arkansas Valley plant at Leadville and the Durango lead smelters are both in fairly active operation, three furnaces are still running at the Garfield smelter, and the Tacoma plant is working about at capacity upon Alaska and South American ores. The Hayden smelter, which was operating mainly on Ray and Magma ores and the El Paso plant, which was treating principally Chino output, have been shut-down for several months. Three furnaces are in operation on lead-silver ores at Murray, as the Pittman Act has stimulated mining greatly in the territory served by that smelter. Also at the Murray plant four furnaces are busy on lead ores. The company's tin refinery at Perth Amboy is still operating, but the Bolivian mines have ceased shipping concentrate owing to discouraging prices prevailing on tin. The company is devoting its attention mainly to the problem of bringing down smelting costs. As yet no severe cuts in wages have been made.

ARIZONA

Jerome.—Calumet & Arizona has started the task of developing the Verde Central property. The work in an exploring drift already proves that the ore found several months ago continues for a considerable distance and is not a pocket as some thought at the time of the find. The property is situated close to that of the United Verde. Calumet & Arizona has appropriated a liberal amount of money for the thorough exploration of the claims of the Verde Central and is intent upon developing something of real value.

Miami.—On October 3 the Miami Copper Co. declared a dividend of 50c. per share, for the quarter-year ending September 30, payable November 15, to stockholders of record at the close of business on November 1.

CALIFORNIA

Anburn.—Charles Arch and Art Sullivan are working on the Hard Climb mine in Duncan canyon, in an effort to find pay-gravel in three adits that have been driven on the property.—William Davis, who is prospecting the Home Ticket mine near Last Chance, has sunk an incline to the depth of 200 ft. and is now driving a raise in search of a channel which is believed to exist under the old workings of the mine.—Joseph Scherer and Davidson brothers are prospecting for pay-gravel on claims in the vicinity.

Bedriek.—All the machinery of a 30-stamp mill and the cyanide plant at the Globe mine has been dismantled and is being shipped to Gold Hill, Nevada, where it will be utilized in the plant being erected by the Comstock Mines Co. There will be 300 tons of machinery to ship by auto-truck from here to Redding and thence by rail to Gold Hill. The truck-freight is 2c. per pound. Much of this machinery was hauled from Redding to the Globe mine by freight-teams at a cost of 4c. per pound.

Downieville.—Excellent gravel is being mined at the Gold Gravel mine near the Sierra-Plumas line. The deposit was reached by a shaft sunk to a depth of 180 ft., following prospecting by drilling.—W. J. Nixon has found high-grade ore on his property on Bear Creek ridge.

Keswick.—The Mountain Copper Co. has completed 9 of the 30 towers for its tram from the Hornet mine to the new town of Matheson on the Southern Pacific railway. The cable, 5.2 miles long, has been received. The company is ballasting the side track at Matheson with slag from the smelter-dumps.

Lewiston.—Lawrence Gardella, of Oroville, is making rapid progress building the gold-dredge that is to operate at the Paulsen ranch. The boat will be launched about

October 15. The hull is 42 by 90 ft. and the buckets are to have a capacity of $7\frac{1}{2}$ cu. yd. The work of the winter will be to install the machinery. The dredge will be in operation early next spring.

Randsburg.—California Silver Rand company reports for the week ending October 3, development work totaling 261 ft.; the main cross-cut on the 11th level was advanced 40 ft. Raise No. 1017 from the 10th level is now in shipping ore of good grade. A new raise is being started from the 10th level to follow the same streak as that being developed by raise No. 1017. South drift No. 913 is still following mill-ore, as is also drift No. 450. No. 2 shaft was not advanced during the past week, as lateral work on the first, second, and third levels prevented work in the bottom. The third-level station was completed, and the first- and second-level ore-pockets were holed through.

Mill construction is continuing steadily with a normal

COLORADO

Aspen.—An order has been placed by the Park Tunnel Tram Co. with the American Steel & Wire Co., of Trenton, New Jersey, for delivery within 30 days of all the necessary equipment for an aerial tram. Preliminary work on terminal site has commenced.

Breckenridge.—The Hethune group of mines, including the Mineral Point tunnel in the Beaver Dam district, has been sold to the Hockmarookus Mining Co., of Denver, headed by a woman who is prominent in mining and oil circles of the south-western fields. The property, including the Blind Tom and Baltimore mines, has produced rich silver-lead ore; settlement sheets show 60 to 90 oz. silver and 50 to 70% lead.

Cripple Creek.—September production totaled 39,404 tons with an average value of \$9.24 and gross bullion value of

The Mill of the Miami Copper Co., with the International Smelter in the Background

crew at work. Production of shipping ore was maintained at the customary rate of 440 tons for the week, all being sent to the Selby smelter.

The Randsburg Silver company advanced its faces 194 ft. during the 25 days ended October 3. Development along the vein 210 ft. east of the shaft is advancing to both the north and south, showing both shipping and milling ore. The work at present is confined to the 500-ft. level. The south-west cross-cut has cut a vein that is believed to be the same as that which the 9th level of the California Silver Rand is following.

Redding.—The option to purchase the Jacob Brothers hydraulic mine below Junction City has been extended by court order until October 1925. The option is held by W. H. Metson of San Francisco. The price is \$21,005. The Jacob brothers, Henry and John, have been dead for several years. The administrator has not been able to trace the heirs in Germany.

\$391,362. Shipments to the Golden Cycle mill for the month averaged 20 broad-gauge cars daily.—A 4-ft. vein of ore sampling 2 oz. gold has been opened by a lessee on the American Eagle.

Hot Sulphur Springs.—A rich find of peacock copper is reported made on the property of the Electro Copper Co. in Eagle and Routt counties, on the line of the Denver & Salt Lake railroad. A tunnel has been driven 800 ft. into a blanket formation, the width of which is undetermined as yet. The average copper content is reported to be better than 4%. The high-grade sampled 37%. A mill has been erected and is being equipped, according to authoritative reports received here.

Salida.—The report of the purchase of the Ohio & Colorado smelter in this city, appearing in the 'Mining and Scientific Press' of August 13, was in error in so far as the name of the purchaser is concerned. Everly & Davis, of New York, are the new owners.

IDAHO

Ivers.—The Lost Packer mine has been bought by the Bingham Galena Mining Co., of Salt Lake City, according to reports. According to an engineer's report the mine has in sight \$300,000 worth of ore ready for the mill and smelter. A vein 3 ft. wide, assaying \$15, has been disclosed by a winze sunk from the tenth or 1000-ft. level. In an upper tunnel an orebody 5 ft. wide and 400 ft. long assays \$10 per ton.

Soda Springs.—Four carloads of equipment for the Caribou Placer Mines Co. has been delivered here and will be transported to the mines 50 miles north-east. The company has purchased two motor-trucks for this purpose. A complete electric-power plant is included in the shipment. The camp will be completed by October 15. The buildings consist of a large mess-hall, storeroom, bunk-houses for the employees, tool-sheds, blacksmith shop, garages, and office building.

MICHIGAN

Houghton.—There was shipped out of the Lake district in September, 7,028,000 lb. of copper, as compared with 5,176,000 lb. for August. While shipments for August were the smallest for the season of navigation to date, the September shipments were the heaviest. This was due to large shipments during the latter part of the month. September shipments bring the total for the season so far up to 30,000,000 lb. Probably 10,000,000 lb. has been sent out by rail in that five-month period. September deliveries while the heaviest for the year were approximately only half of the average total for the corresponding month of normal years.

Although rumors are flying thick and fast in the district, there is no prospect of an immediate re-opening of the Calumet & Hecla mines. These mines still have a large surplus of metal and until it is nearly wiped out the time of resumption of operations will continue indefinite. All of the mines, however, are being kept in good physical condition. There has been little or no serious caving in any of the workings, which are closely watched and repairs made when necessary. Timbering is done when it is needed but this work to date has not been extensive. Some needed shaft-repairs have been made and all openings are kept free of water. Air-pumps are being used almost exclusively for this purpose although a bailer is employed in No. 5, Tamarack.

The Copper Range mines are still experiencing a considerable labor turnover in spite of the unemployment situation in the Lake district. Champion, Baltic, and Trimountain lost a total of approximately 100 men in September, yet more than that number applied for and received work, the company finishing the month with a net gain of 50 in manpower. About 90% of the men taken on were Copper Country workers, the remainder coming from other districts, including some former residents who left to take jobs elsewhere and subsequently returned. Copper Range has been employing experienced men throughout the summer and has increased its payroll by several hundred since spring.

Copper Range has a comparatively small copper surplus, estimated to be not more than 5,000,000 lb. Its sales have been quite heavy of late, one order alone being for 1,000,000 lb. for a domestic consumer.

All openings in the Seneca mine continue in good ground. There is no diminution of values in any of the drifts, and this is particularly true of the 3rd level drift toward Gratiot, the longest opening in the property. The character of the rock in the new drifts from the 7th level is uniformly good and these openings are proving up the mine at depth. It is not yet known when a new hoist will be installed at No. 2 Gratiot shaft, which is to be sunk to a depth of 4900 ft. and connected with the Seneca shaft, but the shaft will be in readiness for immediate sinking as soon as the equipment is in position. It is being kept free of water by use of bailers.

MONTANA

Butte.—For the present at least, the East Butte Copper Co. will sell no more copper at 12½c. per pound, according to authoritative reports. In line with its policy of disposing of only enough metal to keep liquid, the company has been selling at prevailing quotations and has done considerable business at 12½ to 12¾c. per pound. It has now instructed its selling-agent, however, to dispose of no more copper at 12¾c., believing that in the near future higher prices can be obtained. During the last two or three months, East Butte has refrained from publishing its production figures. It is estimated the company has been producing in the vicinity of 1,000,000 lb. of copper monthly, including the product treated for the Davis-Daly Copper Co. on a custom basis. Helped by dollar silver and a good grade of ore—averaging between 4% and 5% copper—East Butte has made a profit each month this year.

Troy.—A five-year lease on the property of the Consolidated Silver-Lead Mining Co., situated seven miles from Troy, has been taken by J. P. Schmuck and C. J. Cavanaugh, of Spokane, who are now driving an adit 300 ft. directly in the orebody.

NEVADA

Cortez.—The raise from the lower or Arctic tunnel of the Con. Cortez Silver Mines Co., driven to connect with the old Garrison tunnel, is progressing in the soft porphyry of the main dike. Some of this material is of milling grade, and ore was stoped in this dike above the upper tunnel.

Crow Springs.—Goldfield and Tonopah men have been rushing into the Crow Springs district, 28 miles north-west of Tonopah and on the Nye-Esmeralda county line. W. E. Edwards and J. A. Logan of Goldfield visited the district and from the 10-ft. shaft on the Betts lease on the claims of the Judson Mining & Milling Co. they obtained three samples as follows: No. 1, 18 in. on the hanging-wall side of the shaft, \$910; No. 2, a check of No. 1, \$1314; No. 3, 7 in. on the foot-wall side of the shaft, \$1872. The ore contains 1 oz. gold to 1000 of silver. Edwards and Logan took a lease on a block 250 ft. from this shaft. The Hudson company was formed as the result of a compromise between Salt Lake and Tonopah men over their locations, which overlapped in places. The 17 claims owned by the company have been held for nearly 20 years by J. R. Walker and C. Walker of Salt Lake City. The development consists of five shafts, 50 to 300 ft. deep, and the 10-ft. shaft sunk recently by Betts. It is said that \$50,000 worth of ore has been produced from these shafts, the average value being \$50 to \$100 per ton. Among those interested in the district are A. H. Jones of Salt Lake City and W. H. Royston, superintendent of the Belmont mill.

Divide.—The shaft of the Tonopah Divide has passed the 1100-ft. point. The shipment of \$30 ore is being continued from the upper levels. The south-east drift on the 800-ft. level recently exposed seams of rich gold ore.

Goldfield.—More claims were located in Esmeralda county during July, August, and September than for many years past, according to Mrs. Rose G. Malone, county recorder. Most of the locations were in the Hornsilver district, with Argentite second, and Lone Mountain third. Argentite is reported to be developing into a district of more than usual importance.

Luning.—Rich silver-lead ore has been found in three distinct veins on what is known as the Wardner group of claims near Lucknow, nine miles north of Luning, near the Rawhide road. The former owner, who shipped some ore from this ground, permitted the claims to lapse and they were re-located by Luning men, who in turn failed to do the location work, and the claims were secured by Charles Ward of Sodaville and Joe Dietz of Luning. They shipped three tons assaying \$334 per ton and netting \$288 per ton.

F. E. Bass, of San Francisco, has an option on the claims and has paid \$1000 down. The high-grade ore is 2 ft. wide.

Reno.—The mill of the Standard Metals Mining Co. in the Peavine district, 12 miles north of here, has been closed while the shaft is being sunk from 300 to 500 ft. Silver-galena ore was exposed in bodies of substantial size on the 200-ft. and 300-ft. levels. A. L. Chappell, the manager, has returned from Pittsburgh, Pennsylvania, where he obtained authority to enlarge the mill in case the ore is found at the 500-ft. level.—The main shaft of the Fravel-Paymaster Mining Co. is being sunk from the 200-ft. level. The property adjoins the Standard Metals mine and the collar of the shaft is 100 ft. higher than that of the Standard Metals Co. The same vein was opened on the 200-ft. level, exposing some good ore. A 75-hp. electric hoist has been installed for sinking. John Reimiller, who opened

500 ft. long, is 300 ft. from the vein at a depth of 600 ft. The vein, 5 to 15 ft. wide, outcrops for 1200 ft. A one-ton trial shipment of ore from a drift from the upper tunnel was made to the MacNamara mill here and the return was \$98 in silver and \$3 in gold. Ralph C. Nowland made an examination of the group for D. C. Jackling before it was taken over by Williams and Jones, but the owners wanted to retain an interest and Jackling would not consider a deal on this basis. The claims are in the Kawich range in the general vicinity of Bellefleur, Silver How, and Clifford.

Tule Canyon.—Silver Hills, Nevada, mines have been shut-down. The report of F. C. Merritt, engineer, estimates the gross value of the available ore at \$25,000, and states that during the past 18 months the cost of mining exceeded the recovery from the ore. W. J. Loring, president, in a letter to the stockholders, says: "Failure of a mining property to realize expectations is, of course, unpleasant, but because one property has failed, there is no reason to assume that all chances of finding a property are lost. With the above information in your hands, as the latest that has been received by me, I submit it to you, and hope that your directors will be successful in finding a property that stands up under a rigid examination."

NEW MEXICO

Raton.—The Hercules Molybdenum Corporation, incorporated under the laws of Delaware, has filed its articles of incorporation with the State Corporation Commission of New Mexico and will maintain an office here. L. S. Wilson is resident agent. The company is authorized to engage in mining and milling. Its authorized stock is \$1,000,000, of which \$154,134 has been subscribed.

Silver City.—The Volcano Mines Co. has been incorporated under the laws of New Mexico with an authorized capital stock of \$2,000,000. The incorporators and officers are: C. W. Mitchell, president and general manager; C. C. Royall, vice-president; Jackson Agee, treasurer; T. C. McSherry, secretary, all of Silver City. The Volcano group is situated near Steins, which recently was the scene of important discoveries. The mine, which has a record of more than \$300,000 in silver, has been idle 20 years. Three hundred tons of ore shipped from the mine recently show an average value of \$40 per ton.

UTAH

Alta.—About 100 tons of ore, valued at \$7000, has been extracted from the new stopes near the top of No. 3 raise at the Alta Tunnel mine and shipped to the Murray smelter.

American Fork.—A bunk-house and several smaller buildings are being erected at the Pittsburg mine. By the middle of November the company expects to have a 6000-ft. tramway constructed that will have a capacity of 150 tons per 24 hours. As soon as the tramway is completed, mining machinery will be installed and development work undertaken from No. 2 tunnel, which gives a vertical depth on the vein of from 800 to 900 ft. In the early days of the camp, Frank L. Hines shipped 11,000 tons of ore from this property, averaging \$1.50 in gold, 15 to 17 oz. in silver, and 48% lead. W. K. Yorston is in charge.

Bingham.—At a meeting of the stockholders of the Bingham-Galena Mining Co., on October 3, it was voted to increase the number of shares from 1,000,000 to 4,000,000, and decrease the par value of the stock from \$1 to 25c. per share. The additional stock authorized will be placed in the treasury, to be used for the acquisition of the Lost Packer property in Custer county, Idaho, and any other properties that the board of directors may deem advisable to acquire.

Eureka.—The shaft-house at the Apex-Standard mine was destroyed by fire on October 1. The fire originated in the change-room. Only nominal damage was done to the com-

Map of Nevada

the Engels mine in Plumas county and the Mary mine at Silver Peak, Nevada, has been made superintendent.

Taylor.—The re-modeled plant of the Wyoming Mining & Milling Co. has been started; 40 to 50 tons of ore per day are being milled, coming principally from the old dumps. If the recovery in the mill is satisfactory the orebody will be mined.

Tonopah.—J. Hampton Williams, noted for his connection with the discovery and development of the California Rand mine at Randsburg, California, and January Jones, a promoter in the early days of Goldfield, have taken over 10 claims at Eden Creek, 50 miles east of Tonopah, and a company is to be organized by them for development of the group. The claims were sold by Mark H. Bradshaw, consulting engineer of Tonopah, who held an option. The ore is silver, in both sulphide and chloride form, and there is a small gold content. The principal work consists of two tunnels, one cutting the vein at 225 ft. The other tunnel,

pressor, hoist, and other machinery. It is believed development work can be resumed within ten days.

Ore shipments for the week ending October 1 totaled 136 cars, as compared with 144 for the previous week. The Chief Consolidated shipped 38 cars; Tintic Standard, 35; Victoria, 10; Iron Blossom, 10; Iron King, 8; Dragon, 10; Eagle & Blue Bell, 8; Swansea, 5; Sunbeam, 4; Colorado, 2; Gemini, 2; Gold Chain, 1; Yankee, 1; Eureka Hill, 1; and Alaska, 1.

Operations continue satisfactory at the Zuma property. The sinking of the shaft will continue until the 1200-ft. level is reached, at which depth a tunnel will be driven. Ore is showing from the 500-ft. to the 875-ft. levels.

Moab.—The Blanding Irrigation Co. has acquired control of the Dream mine, one of the oldest in the Blue Mountain district. About \$35,000 has been expended in developing the property. The new owners plan to drive a 1000-ft. tunnel to cross-cut the vein at a depth of 700 ft. It is reported that approximately 60,000 tons of ore is in sight. The mine is situated some distance from the main line of the Denver & Rio Grande railway, and, on this account, but very little ore has been shipped.

Park City.—Shipments of ore for the week ending October 1 totaled 1805 tons, as against 1436 tons for the preceding week. The Silver King Coalition shipped 827 tons; Judge allied companies, 586; Ontario, 410.

Between 30 and 40 tons of ore has been extracted from the orebody in a winze from the J. C. R. drift at the New Quincy property. While grab-samples show as high as 200 oz. silver per ton, the average for the lot is probably 100 ounces.

Salt Lake City.—During 1920, there was an average of 4965 men employed in the metal mines of Utah, 1534 in ore-dressing plants, and 2315 in smelters, making a total of 8814 employees. During 1919, there was an average of 8522 men employed in the metal-mining industry of the State; 13,901 in 1918; and 16,505 in 1917.

WASHINGTON

Keller.—The Addison Copper Co., owner of a property $3\frac{1}{2}$ miles north of here, has resumed operations, according to C. A. Gray, manager. The Federal shaft, down 37 ft., will be extended 200 ft. The ore in the bottom of the shaft is worth \$76 per ton, of which \$15 is in silver; the vein is $4\frac{1}{2}$ ft. wide between well-defined walls. It is proposed to drive the Mammoth tunnel to a point under the Bunker Hill shaft, 110 ft. distant. The vein is 6 ft. wide in the bottom of the shaft and assays 21% copper, 5% lead, and 52 oz. silver per ton. The mine is equipped with a compressor, and with the installation of another hoist the property will be developed to a depth of 600 feet.

WISCONSIN

Cuba City.—Shipments of water-white high-grade sulphuric acid are made at the rate of about 200 tons per week.

Higher prices for lead ore have stimulated lead mining. Three new producers are being developed and equipped in this district. One on the Kluck farm. Another is known as the New Lead Co. The third is on the Pascoe farm. Pumping machinery is being installed.

Day Siding.—The North Unity mine continues production of zinc ore, shipping in small lots weekly to the National Separator. Sales of lead ore were made the first week in October amounting to 100 tons.

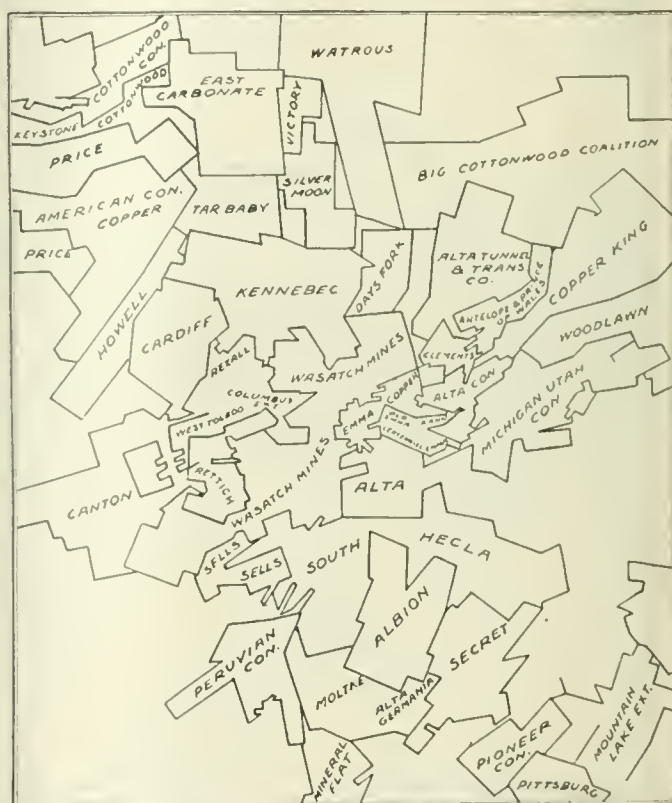

Galena.—The Galena Iron Works Co., operating a foundry and mining machinery repair shop, resumed operations recently and is again finding sufficient demand for its supplies and service to operate steadily. This is regarded as a fair indication that mining will revive soon.

Livingston.—The Vinegar Hill Zinc Co. continues shipping zinc concentrate from the Yewdall mine, 300 tons per

week being sent to the National Separators at Cuba City, there to be converted into sulphuric acid and high-grade magnetic-separator blends.

Platteville.—There has been no change in the zinc-mining industry in this district. Production of zinc concentrate is confined to mines outputting to provide base for acid manufacture. The lead-ore outlook has brightened immensely. The price of ore has advanced to \$60 base, 80% metal content, and on this basis sales have been made bringing a top price of \$62.50 per ton. Buyers and sellers alike are optimistic regarding the maintenance of these higher figures, which have stimulated more activity at mines, especially where indications point to a fair recovery. The volume of shipments is increasing and a fair portion of the reserve held in the field, estimated at about 3000 tons, will be sold.

The Block-House Mining Co., regardless of the depression, is constructing a new 150-ton zinc-mill on the Goke farm,

Claim Map of the Alta District in Utah

east of the Schroeder mine and mill, also owned by this corporation. The new structure is enclosed. Head-frame and shaft-haue are being built.

The Zinc Roofing & Products Co. has closed contracts with the Elkhorn high-school for a zinc roof; with the State government for a batten sheet-zinc roof for the heating-plant of the university; and with the Platteville State Normal School for a corrugated-zinc roof for Machinery hall.

Shullsburg.—The Rodhams Mining Co., idle since early last spring, has resumed operations. A new vein is being opened and the new mine-site equipped. Sales of lead ore the first week in October amounted to 150 tons, consigned to the Federal Lead Co.

BRITISH COLUMBIA

Ainsworth.—W. E. Zwicky and R. Foulkes have leased the Krao mine and have moved a compressor from the Cork-Province to the property.—George McPherson and Jack Sherman have leased the Silver Hoard mine.—The Federal government is enlarging the wharf to facilitate ore shipping.

Alice Arm.—The Taylor Mining Co. has re-opened the Dolly Varden mine, and will put the railway in operation as soon as new cars, which have been ordered, arrive. Work will be principally directed toward development, with a view to putting the mine in good producing condition for next season; it is expected, however, that about 4000 tons of ore will be shipped before winter snows prevent further operation of the railway. About 30 men are employed, and, when the railway is closed, half of these will be moved to the Wolf mine, and development at both mines will be continued through the winter. One of the compressors at the Dolly Varden is to be moved to the Wolf, and the hydro-electric plant, which was completed last year, will provide power for all machinery at both mines.—It has been found impossible to complete the road to the Homestake mine before winter sets in; accordingly work will be suspended until spring.

Nanaimo.—F. H. Fraser and E. W. Lewis, representing the Vancouver Magnetite Steel Smelting Co., have been in the city endeavoring to obtain concessions with a view to erecting a 50-ton electric smelter for the manufacture of pig-iron and steel. The company proposes to develop its own power from the Nanaimo river, and to erect furnaces similar to those now in use in Norway and Sweden. The company claims to have spent \$67,000 in experimental work and to

Miguel Chavez of the Santiago Papasquiaro district has re-located the old Santa Eduwigis and El Tejon mines on the south-east side of the Alejandra range of mountains in the municipality of Otaez. The two properties are to be retitled under one name, El Tejon.

Luis J. Peach is interested in some new properties in the Otaez mining district which he is preparing to develop.—Gerald E. Norton has made application for another group of five claims in the Pueblo Nuevo district which are to be titled under the name of El Bello Encanto. They are situated west of the Javali mine.—Albert Niebla, of Topia, has taken over the San Jose mines in the municipality of Tamazula. A shaft is to be sunk on the main vein, and lateral development work will follow.

Zacatecas.—A number of local mining men of Chalhchihuites have taken over the Auxilladora group of silver-lead mines in the San Jose mountains at San Juan, which is situated about two miles from Chalhchihuites. The properties are to be worked by Susano Banuelos, Benjamin Rodriguez, Agustin Ramirez, and others.

A large group of mines, comprising about 28 claims in all, has been located by Ubaldo Fernandez in the Chacuaco mining district near San Alto. The survey will include the old San Eliseo silver-lead mine which has been abandoned for a number of years and was recently declared forfeited by the secretary of industry and commerce.

John Emerson, Charles E. Snyder, and George Davis are developing a number of properties in the Sombrerete district.—It is rumored that San Antonio capitalists will shortly begin the erection of a concentrating plant at Chalhchihuites for handling the ores from the mines and some of the old dumps which contain good ore.

ONTARIO

Cobalt.—Rain has become general throughout Northern Ontario, and the mine operators feel assured of all the hydro-electric power required to maintain operations at full capacity during the winter.

Silver is being produced by the La Rose Consolidated from four properties, these being the original La Rose, Princess, University, and Violet. The recently discovered vein at the 570-ft. level of the Violet contains silver across a width of six feet. From all four properties an average of 120 tons of ore is being drawn daily. Production is at the rate of over 40,000 oz. silver per month and the output for the current year will be the highest since 1917.—During the fiscal year ended August 31, the Kerr Lake Mining Co. realized \$478,979 net profit. This came largely from the company's operations in Utah, and compared with net profits of \$916,089 during the previous year.

The Nipissing has started a third diamond-drill hole on the Rochester property, which it holds under option in the Porcupine district.—A small mining plant is being installed by the Premo-Silver-Cobalt Mining Co. on property situated near Latchford.

Kirkland Lake.—At the King Kirkland the work of surface exploration has almost been completed with the result that 32 veins have been exposed, enabling the management to select the most suitable location for a central shaft. A large compressor will be installed and development work carried to deep levels.

The Comfort-Kirkland has an electrically-driven plant in operation and is sinking a shaft. Good results are reported. The orebodies of the Ontario Kirkland run in the direction of the Comfort.

The Granby-Kirkland has uncovered and is opening up its 14th vein which is 5½ ft. in width. Channel samples show high gold content and the wall-rock is well mineralized.

Larder Lake.—The Crown Reserve which is conducting exploration work on a wide mineralized body has found a good body of ore which yields \$6 per ton in gold.

The Mining Districts of Wisconsin

have produced high-grade steel from the British Columbia magnetite ores. It further claims that it is backed by British capitalists that are prepared to put \$5,000,000 into the enterprise, provided satisfactory terms can be made with the city.

Vancouver.—The Roses Gulch Placer Gold, Ltd., has been organized in this city, with a capital of \$100,000 in \$10 shares, to operate a group of placer claims near the Bullion mine on the Quesnel river.—According to the Dominion Bureau of Statistics, the output of lead for the first half of the present year is 90%, and the output of zinc 70%, of the total for the whole of last year.—The Rock Creek Mining Syndicate has been organized in this city to operate a placer-gold deposit at the mouth of Rock creek, a tributary of the Kettle river.

MEXICO

Durango.—Antonio Soto, representing Manuel Juarez, has made application for titles to a group of four claims to be known as Natalia No. 2, situated in the Plomoso mountains of the Guanacevi mining district. The new location lies in the vicinity of the Primavera, La Aventurera, La Cumbre, and the Torreón mines which produce gold-silver ore.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

C. W. Purington is on a visit to Washington.
Bulkeley Wells was at Grass Valley this week.
Charles W. Teets has moved from Denver to Torrington, Wyoming.

Whitman Symmes has returned to San Francisco from New York.

Roy E. Cohn has returned from Chile to San Francisco for a short visit.

J. R. Kingham has moved from Victoria, B. C., to Boston, Massachusetts.

A. W. K. Billings has returned to New York City from Barcelona, Spain.

Harry R. Bischoff has moved from St. Paul, Minnesota, to Wallace, Idaho.

Glenn L. Allen, of Warren, Arizona, is at Guadalupe, Zacatecas, Mexico.

J. C. Kennedy has moved from Yerrington, Nevada, to Sacramento, California.

Etheredge Walker has moved from Trinity Center, California, to Boise, Idaho.

J. N. McLeod has moved from Carmangay, Alberta, Canada, to Dividend, Utah.

Corey C. Brayton is on a trip through British Columbia, Idaho, Montana, and Utah.

R. C. Gemmell has returned to Salt Lake City after a short vacation in southern California.

A. Doyle, formerly with the El Oro Mining & Railway Co., in Mexico, is at Richmond, Virginia.

G. Howard Birch, president of the Dan Creek Mining Co., at Dan Creek, Alaska, is in New York.

Joseph Errington was recently at Toronto for the annual meeting of the McIntyre-Porcupine company.

William Wraith, general manager for the International Smelting Co., has returned to New York from the West.

Charles W. Stimpson, of Salt Lake City, passed through San Francisco on his way to Honolulu, on a brief holiday.

E. J. Raddatz, president of the Tintic Standard Mining Co., has returned to Salt Lake City after a visit to Los Angeles.

Arthur L. Walker, Professor of Metallurgy in Columbia University, has returned to New York from a holiday in France and England.

H. L. Payne, of the firm of Baverstock & Payne, of Los Angeles, was engaged this week as expert chemist in legal controversies in Arizona.

Dwight C. Bardwell is now assistant physical chemist at the Rare and Precious Metals Station of the U. S. Bureau of Mines, at Reno, Nevada.

R. G. Hall, resident manager for the Burma Corporation, at Namtu, Northern Shan States, Burma, expects to return to the United States shortly.

J. J. Gorrell has resigned from a position in the technical direction bureau of the Aluminum Company of America to become chemist with the Cambria Steel Company.

H. W. Thomson will represent the 'Canadian Mining Journal' at the American Mining Congress convention and exposition to be held at Chicago from October 17 to 22.

C. W. Botkin, recently research engineer at the Colorado School of Mines, is now the head of the Department of Chemistry, New Mexico College of Agriculture and Mechanic Arts.

Martin Schwerin has completed three years of management of the Spar Mountain Mining Co., at Cave in Rock, Illinois, and will resume the practice of consulting mining

engineer after January 1, with offices at 42 Broadway, New York.

Walter Fitch, president, and Cecil Fitch, general manager, for the Chief Consolidated Mining Co., have returned to Eureka, Utah, from a holiday at Coronado Beach, California.

J. O. Elton, recently assistant manager of the Great Falls smelter of the Anaconda Copper Mining Co., is assistant general manager for the International Smelting Co., succeeding O. M. Kuchs.

M. H. Roberts, R. C. Tolman, and W. L. DeBaufre are to constitute a board of engineers, appointed by the Director of the U. S. Bureau of Mines, to study the production of helium at Petrolia, Texas.

H. L. Brown, who has been with the American Metal Company for several years, has just been appointed consulting mining engineer to the Compañía Minera de Peñoles, which is one of the subsidiaries of the American Metal Company.

O. M. Kuchs, who has been assistant general manager in Utah for the International Smelting Co., has become general manager for the Andes Copper Mining Co., with headquarters at Potrerillos, Chile. He sails from New York on October 26.

Bernard MacDonald, previously in charge of the mining and milling operations of the Veta Grande unit of the American Smelters Securities Co. in the Parral district of Mexico, has opened an office in the city of Parral, and will resume consulting practice.

Walter J. Eaton has resigned as superintendent of the Nalea and Santa Eulalia units of the American Metal Co., at Durango, Coahuila, Zacatecas, and Chihuahua, Mexico, to become mine superintendent for the Smuggler-Union Mining Co., at Telluride, Colorado.

OBITUARY

S. S. Voorhees, for eleven years on the staff of the U. S. Bureau of Standards, died at Portland, Maine, on September 23, aged 54. He was educated at the Lehigh and George Washington universities; prior to joining the Bureau he was in the research department of the Pennsylvania, Southern, and New York Central railroads.

Charles Walter Whitley, vice-president of the American Smelting & Refining Co., in charge of the company's plants in the United States, died of pneumonia on October 9 at St. Luke's hospital in New York. He returned a short time ago from a four weeks trip to Mexico. He was born in Chicago on June 20, 1869. Completing his elementary-school education in that city, he entered the Massachusetts Institute of Technology in 1887, graduating in 1891. He entered the street-railway business, shortly after his graduation, in the capacity of electrical engineer for the Chicago City Railway Co. Subsequently he assumed the management and control of the Canyon ferry dam on the Missouri river, 22 miles from Helena, Montana, and while in that State became identified with the mining and smelting business. He was manager of the United Smelting & Refining Co.'s plants at East Helena and Great Falls, later becoming general manager for the American Smelting & Refining Co., with headquarters at Salt Lake City. Subsequently he became vice-president of that company, making his office in New York after having been placed in charge of all the smelting and refining plants in the United States. He married Dorothy Kinney, of Rock Springs, Wyoming. Four children were born to them, two daughters and two sons. Although his personal attention was given to the smelting company of which he was vice-president, he was interested in many large corporations, being a director of the American Smelting & Refining Co. and of the American Smelters' Securities Co., president of the Utah Steel Corporation, and director of several banking companies in Utah. He leaves a host of friends who will mourn deeply his untimely death.

THE METAL MARKET

METAL PRICES

San Francisco, October 11

Aluminum-dust, cents per pound.....	05
Aluminum, sheet, cents per pound.....	58
Antimony, cents per pound.....	6
Copper, electrolytic, cents per pound.....	13.25
Lead, pig, cents per pound.....	4.05-5.95
Platinum, pure, per ounce.....	\$80
Platinum, 10% iridium, per ounce.....	\$98
Zinc, slab, cents per pound.....	0.25
Zinc-dust, cents per pound.....	0.25

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

REPORT OF CHAMBER OF COMMERCE OF THE UNITED STATES ON EUROPEAN AFFAIRS

A report has been published from a special committee from the Chamber of Commerce of the United States, the clearing house of the chambers of commerce of the country, that went to Europe to study conditions there at first hand. Not a name on that committee is known in politics. Every name on it, however, is known in the world of business. Query: Are business men fit to deal with such a question? We think they are better qualified than politicians with axes to grind. The reporters, we should judge from their report, looked at things from the economic point of view as it bore upon the United States; and that is what they went to Europe for, not in the interest of the latter but of their own country, says the "Rocky Mountain News".

One finding from that report involves the whole question of depression as it affects this country along with others less fortunately situated: "The consumption of three hundred million people is reduced to 30% of normal. The world is operating on a basis of less than one-half of the pre-war standard."

What is going to be done about it? This committee, composed of men of large affairs, has no panacea that would restore the world to its equilibrium overnight after seven years of debauch. But it does point out that unless the United States comes forward as a stabilizer Europe will go from bad to worse. That continent is dancing on the top of a volcano. The committee is convinced that the United States cannot refrain from active participation in the settlement of Europe's economic, financial, and political situation without loss to itself. If Europe cracks, something will happen over here.

"In every country visited the opinion was expressed that neither western nor central Europe can be restored to a condition which promises hope and progress for the future without our assistance," the report states. "Every country desires our friendship and assistance, and it is apparent we can participate in the restoration of commercial and industrial productivity on any reasonable and consistent terms, either by modification of the Versailles treaty to meet the policies of the United States, or independently of it."

Without attempting to speak for political Washington, we believe that what the committee suggests will be the ultimate conclusion formed at the capital, that the government of the United States shall take a hand on its own terms in preventing a second debacle and rescuing the continent from its own follies; and this will be done not as an altruism but as a matter of sound foresighted policy.

Germany is the weakest portion of the volcano's rim. Its present government is seeking earnestly to carry out its agreements and make restitution, but opposed to it is the militaristic-monarchical party, still powerful, that demands repudiation and defiance. If the present government fails, France will step in and take possession of what it requires, as a guarantee for its war losses, in the industrial parts of Germany, and this will lead to a complete break and discord among the allies, with war threatening on every front. And there is but one nation that can enforce peace without the necessity of an army.

MONEY AND EXCHANGE

Foreign quotations on October 11 are as follows:		
Sterling, dollars:	Cable	3.86 ¹ / ₂
	Demand	3.87
Franc, cents:	Cable	7.37
	Demand	7.39
Lira, cents:	Demand	4.05
Mark, cents		0.86

Eastern Metal Market

New York, October 5.

Strength characterizes all the markets; further advances in most are noted.

Demand for copper is improving and prices are a little higher.

The tin market is moderately active and if anything firmer.

Demand for lead is good with prices firmer at last week's levels.

The zinc market is more active and higher.

Antimony is considerably stronger.

IRON AND STEEL

For the second time since the low dip in July, pig-iron production is an index of definite improvement in the steel industry. The pig-iron total for September was 985,529 tons for 30 days, 32,850 tons per day, as compared with 954,193 tons in the 31 days of August, or a daily rate of 30,780 tons, according to the blast-furnace returns of 'The Iron Age'. Fourteen blast-furnaces were blown-in during September and two went out, making a net gain of 12. The daily capacity of the 82 furnaces active on October 1 is estimated at 35,650 tons, as against 30,770 tons for the 70 furnaces in blast one month previous. The Steel Corporation blew in six furnaces last month, in view of the increased steel production required by recent large orders in sheets and wire products. A further pig-iron gain is indicated for October, seven blast-furnaces being scheduled to blow-in during the first half of the month.

Structural-steel lettings of the week, covering sizable projects, aggregate fully 18,000 tons, with an 8000-ton structure for a Masonic temple at Detroit the conspicuous item, and fresh proposals total about half the amount, including 3000 tons for a new roadway for the Manhattan bridge in New York.

COPPER

It is confidently asserted that September sales of copper totaled 100,000,000 lb. and it is generally stated that there are inquiries in the market for 15,000,000 to 20,000,000 lb. more, including an inquiry for 10,000,000 lb. from the American Brass Co., which bought 5,000,000 lb. a week ago. In fact some consumers who thought they could buy under 12c. a few weeks ago are finding it difficult if not impossible to buy under 12.25c., delivered, if at that. Prices have advanced until electrolytic copper for early delivery (October) is quoted today at 12.37½c., New York, or 12.62½c., delivered, with the market strong and more cheerful than in many weeks. Forward positions by months are ¼ to ½c. higher.

TIN

This market is moderately active and steady. There continue to be fair sales of Straits tin both prompt and future; at least 20 tons was sold last Friday, September 30. Both consumers and dealers were participants. Prices continue to hover around 27c., New York, for spot Straits with the closing price yesterday at 26.75c., the same as a week ago. Statistics for September show that deliveries into consumption were 260 tons, of which 2500 tons came in at Atlantic ports, with 1756 tons in stocks and landing on September 30. Imports for the first nine months of 1921 have been 1580 tons against 26,900 tons for the same nine months in 1920. American pure tin is quoted at the same price as Straits tin or 26.75c. for prompt shipment.

LEAD

This market is not quite so active as it has been, but it continues strong with demand moderate and steady. The

leading interest continues to quote 4.70c., New York and St. Louis, while independent sellers accept business at 4.50c., St. Louis, but ask from 4.70 to 4.75c., New York, or a slight advance over the major interest.

ZINC

Prices have continued to advance until prime Western is now quoted at 5.05c., St. Louis, or 5.55c., New York, which is 20 points above the levels prevailing a week ago. This is due to two causes besides the increased demand from some consumers. Producers have sold a large part of their output for October this early in the month and are not selling their stocks produced at higher prices. The principal demand is reported as coming from galvanizers.

ANTIMONY

Demand is moderate but the market is firm at 5c., duty paid, for wholesale lots for early or October delivery.

ALUMINUM

Virgin metal in wholesale lots for early delivery is quoted at 24.50c. f.o.b. plant, with the imported metal of the same grade available at 18 to 19c., New York, duty paid.

ORES

Tungsten: There is no change in conditions and there is no demand with quotations nominal at \$3 per unit upward, depending on grade and quantity.

Ferro-tungsten: Quotations for the domestic alloy remain nominally unchanged at 40 to 45c. per pound of contained tungsten. The foreign alloy is quoted at 50c. per pound of contained alloy.

Molybdenum: There is no change with quotations nominal at 50c. per pound of MoS₂ in regular concentrates.

Manganese: There is absolutely no interest with stocks large as well as imports. Quotations are nominal at 20c. per unit, seaboard.

Manganese-Iron Alloys: German ferro-manganese is reported offered at about \$53, seaboard, and sales are heard of but not confirmed. American and British alloys are unchanged at a basis of \$58.35, seaboard. Spiegeleisen is quoted at \$25 to \$26, furnace. There is but little demand for either alloy.

PRICES FOR CRUDE-OIL

The estimated average value of crude-oil produced in the United States in August was \$1.07 per barrel as compared with an average for the first eight months of \$1.67 per barrel and high in 1920 of \$3.07. August represents the bottom price levels, if advances of 25 to 50c. per barrel which have taken place within the last month are held. The August average is the lowest at which crude-oil has sold since 1915, when it was 64c. per barrel. In 1916 the average was \$1.10, and it mounted steadily in the years following until the peak of \$3.07 was reached in 1920. Gradual recessions occurred during the first eight months of 1921, the total decline compared with the peak of 1920 being 65%. The average of \$1.07 per barrel compares with \$1.10 in 1916. Consumption of oil has increased largely since that year because of the increase in the number of motor vehicles in the United States. In 1920 there were 9,211,000 cars, compared with 3,512,996 in 1916 and 2,445,000 in 1915, a gain of 6,766,000 cars since 1915. Another factor causing greatly increased consumption of oil is the use of fuel-oil in ships, industrial plants, and railroads. Consumption of fuel-oil alone in 1920 amounted to approximately 208,000,000 bbl., accounting for 40% of the quantity of all products consumed that year.

T. A. RICKARD, - - - Editor

WE have received a postcard from the Secretary of the Institute warning us that the forthcoming issue of the Institute magazine will contain sundry articles by gentlemen of considerable prominence. Was this done to arrest a customary motion toward the waste-basket, or for the purpose of spending a little money?

PROSPECTING needs all the extraneous help that can be given to it; sometimes the unexpected and the bizarre may prove of importance. Mr. Frank D. Paglinchi, while making an examination of a prospect in Venezuela, frequently heard the sharp cry of a bird, gray in color, and about the size of a robin. It is called locally *el minero* (the miner), and its presence is always taken as an indication of the proximity of quartz. Mr. Paglinchi was advised that, if he wished to find gold, he should look for a *mora* tree. Seeing one of them near the vein he was examining, he continued his researches, to find that the tree evidently thrived in siliceous ground, and bore berries that were eaten by the bird. Thus it is that whenever such a cry is heard, quartz may be found in the vicinity; it may or may not be auriferous, but the prospector is helped if he be shown where to look for it.

ON another page we print an article on 'Shop-Operations and Repairs on Gold-Dredges', by Mr. Frank A. Stanley, editor of the 'Western Machinery World', a monthly periodical published in San Francisco. Mr. Stanley's viewpoint, primarily, is that of the mechanic; he discusses sundry features of the repair work done by the Natomas Company of California in its shops at Natoma, the base of operations for seven or eight large dredges that the company is now operating. When a placer is once tested and a decision is reached as to its suitability for dredging, the problems of the engineer are principally mechanical. His task is to move gravel economically. The most important item in the cost of dredge-operation, aside from interest on the invested capital, is the maintenance of the machine, which inevitably is subjected to the most severe strains. Accordingly, the superintendent's efforts are devoted largely to obtaining the most durable materials for the working parts, and to prolonging the life of them by devising economical methods of repair. Mr. Stanley has touched only the high-lights of a few important operations. For

instance, his mention of the heat-treatment of bucket-pins forged of chrome-vanadium steel introduces a topic about which pages might be written. The use of the oxy-acetylene torch for welding is an operation that dredge engineers have developed to a high degree of efficiency, but that still affords opportunity for improvement. The excellent illustrations that accompany Mr. Stanley's article show a number of uses of the oxy-acetylene torch. We offer our columns to others who are interested in exchanging views on these subjects.

IN our issue of July 9 we offered some gratuitous advice to the officials of the Bingham-Galena Mining Company, who, in face of strong opposition on the part of reputable mining people at Salt Lake City, persisted in allying themselves with Jacob S. Herzog, *alias* George Graham Rice, in the promotion of their enterprise. Mr. E. C. Bellows, Commissioner of Corporations for the State of California, refused to allow stock of the Bingham-Galena company to be sold in this State; his action evoked sundry caustic protests from Child, Barclay & Company, a firm of brokers at Salt Lake City, who had circularized some of Rice's former victims in California with the bait that an investment in Bingham-Galena would recoup their losses in the notorious Broken Hill fiasco. The Utah State Securities Commission at that time took the stand that the conduct of the company's affairs afforded no ground for a refusal to permit the stock to be marketed in Utah, but apparently its peculiarly friendly attitude has changed. It seems that the Bingham-Galena officials have been cited to appear before the Commission to explain sundry transactions; coincidentally, the stock has taken a tumble on the Salt Lake Exchange to 6 cents from a high point of 38 cents. Meanwhile Rice and his one-time brokers are "engaged in mutual recriminations and accusations of bad faith and worse", according to the 'Salt Lake Tribune'. Mr. Allen T. Sanford, a reputable attorney of Salt Lake City, prominently identified with the Bingham-Galena company, has succeeded in obtaining the acceptance of his resignation, which he submitted some weeks ago. Rice is the kind of man who, on account of some peculiar kink in his moral fibre, has an abhorrence of honest dealing. We trust that Child, Barclay & Company, Mr. Sanford, the members of Utah's Securities Commission, and the ignorant victims who lost their

money gambling in the stock, all have learned a lesson; and we hope that legitimate mining in Utah has not suffered too seriously from the fiasco.

NOMINATIONS for the presidency of the Institute are in order. We understand that Mr. Edwin Ludlow is unable to accept re-election, therefore the choice of a successor must be made by the committee appointed for that purpose. The chairman of the committee is Mr. Arthur Thacher, of St. Louis, and it was hoped by many members that he might be prevailed upon to accept the nomination, but, we are informed, he has declined the honor. For that we are sorry, because Mr. Thacher in character and in reputation is of the requisite stature and would have made an excellent president. At one time there was talk of selecting a Western man; whereupon many of us on this side of the continent urged the nomination of our 'favorite son', Mr. Charles W. Merrill, but he also was compelled, by the exigencies of his own business, to decline. The search for suitable presidential timber appears to have turned on its tracks and is now resting in the East, where it has lit upon Mr. Arthur L. Dwight. If we are not to have a Western man for president, then by all means give us Mr. Dwight, whom Western men will be glad to accept as the titular chief of the mining profession in this country. A New Englander by birth, a graduate of the Columbia School of Mines, a metallurgist of the first rank, an officer in the Engineer Corps of the Army, a scholar and a gentleman, he has qualifications that all will acknowledge gladly. His record in the War was fine; he served with the 11th Engineers and retired with the rank of Lieutenant-Colonel. The British gave him the D. S. O.; General Pershing cited him for specially meritorious conduct. He knows the West; for 13 years he was at the Colorado smelter in Pueblo. We venture to speak for our readers in welcoming his nomination.

DISCUSSION this week opens with a letter from Mr. Henry F. May on the revision of the mining law. Mr. May is a lawyer, now resident in San Francisco but formerly in Denver, where he took part in many important litigations arising from disputed interpretations of the mining law, so that he knows well whereof he speaks. Among other points he refers to the sequestration of the public domain and the check to exploratory work that follows from the holding of claims without either exploration or development, and therefore he demurs to the postponement of work for discovery, by "the mere payment of comparatively small sums of money". The prospector thinks the sum is large; to him it may be so, but to the mine operator of large means there is given the opportunity to 'tie up' considerable areas at will, without doing the one thing that the law is supposed to stimulate, namely, the finding of ore and the production of the metals for industrial purposes. Mr. William Crocker appreciates both the good and the bad features of the proposed revision. He endeavors to expose the conditions to which the law would apply undesirably, and argues in behalf of the granting of ground

sufficient in area to encourage large-scale operations. His text is "the economic unity of an orebody", but the suggestion he makes is, we believe, hopeless; for he asks for a classification of ore deposits and an application of the old and new laws respectively in accord with the classification. Mr. Robert J. Burgess contributes some interesting notes on the system of veins in the Big Bend district. Mr. G. W. Gilman describes the method of treating gold-silver ore at Hayden Hill, California. Mr. John T. Reid, of Lovelock, Nevada, an experienced mining engineer, makes a plea for help to the prospector. We give space to him although we find it impossible to endorse his idea, which is that the prospector should be compensated for his work on a claim, even if it prove unfruitful or otherwise unsuccessful, by being permitted by law to file a lien upon the ground, such lien to be met by any subsequently successful prospector or owner of the claim. In other words, Mr. Reid thinks it unjust that a worthy prospector should not be compensated for his hard, even if fruitless, labor on a claim that subsequently proves to be the basis of a profitable mine. The idea is generous, but it is wholly impracticable. Every day men are starting enterprises that will fail, but that serve as stepping-stones on which other men cross to affluence. We join with Mr. Reid in goodwill to the prospector, but we recognize that he—the prospector—is no more entitled to special consideration than others who start and fail. It is 'the rub of the green', as a golfer would say. Mr. Crocker has a second letter in this issue; it discusses Mr. Gerald H. Hutton's excellent article on the valuation of placer deposits. We shall leave it to Mr. Hutton to reply to Mr. Crocker. Mr. L. O. Howard, Dean of the School of Mines in the State College of Washington, contributes a friendly criticism of the cases cited by Mr. Morton Webber to illustrate the difficulties arising in the valuation of old mines. Mr. Webber will reply in due course. A note on the use of pulverized coal in smelting operations is contributed by Mr. R. E. H. Pomeroy, of the Bonnot company.

The Interrogatory

In this issue we end the publication of the replies sent to us in response to an interrogatory in regard to the present condition of the metal-mining industry. This interrogatory was intended primarily to help our advertising clients, but it yielded information that we felt sure would interest our readers as well, so it was reprinted serially in three consecutive issues, after having been sent to the advertisers in pamphlet form. The answers are interesting because they come from the right men; it would have been improper, without specific permission, to have published the replies over the signatures of the individuals, but we gave a list of those who answered, so that the reader might judge for himself as to the reliability of the source as a whole. It will be noted that the preponderance of opinion favors the belief that gold mining is expanding at the present time. One reply lays stress on the fact that the stagnation in base-metal mining is stimulating the search for gold and

the re-opening of idle or abandoned gold mines. The gradual reduction in the cost of labor and of supplies favors activity in this direction, says another. In regard to the McFadden bill, it is evident that not much help is expected from this proposed legislation. Opinions are divided; naturally, if any special legislation favoring gold mining is likely to be passed, it will be welcomed by those whom it will help, but many of them are honest enough to recognize the improbability, and even the impropriety, of such legislation, and are content to have the free market for gold maintained without prejudice. In the long run, we believe, no good can come to the miner from any legislative interference with the status of the metal. Conditions more favorable to gold mining are assured in the ordinary course of events. In regard to improvements in mining machinery, it is noteworthy that several replies join in laying stress on the need for a machine for scraping and shoveling broken rock underground. "The great trouble", says one engineer, "is that all shoveling machines are too expensive, too cumbersome, and too heavy." What is wanted, he adds, is a machine that will work economically in an ordinary drift. We shall be publishing an exhaustive article on the subject at an early date. Many of those whom we interrogated are engaged in copper mining, hence the replies under this heading are especially interesting. Everyone, of course, would like to know when the big copper mines are going to resume their normal activity; so we asked the question. It will be noted that the replies give the date as early as the beginning of next year and as late as July—a difference of six months. If an average can be made in such a matter, it would point to the spring, say, March next. The condition of the copper market has improved considerably since the interrogatory was answered. We hazard the forecast that the resumption will not be general at first, because the low-cost producers will be willing to start before the high-cost producers, the divergence of interest being sufficient to cause a lack of agreement in policy. If the price of copper remains low, it is likely that the harmonious efforts of the big mining companies to sell their product jointly will cease, and there may follow keen efforts for the domination of the market on the part of the low-cost producers, notably those who control the so-called porphyry mines and the bonanzas. Several of the replies from Arizona exhibit just resentment at the money wasted in that State by lavish legislative appropriations. The claim is made that several mines can produce and market their copper at New York for 10 cents per pound. Many efforts are being made to decrease the costs of operation by better methods and mechanical devices, so that the period of inaction is not unproductive. All the responders are awake to the need for widening the market for copper products, and approve of the Copper & Brass Research Association, which was organized recently for that very purpose. We venture to direct attention to the need for co-operating with the retailers. It is likely that ultimately some of the copper companies will unite in fabricating copper

and brass products on a large scale, imitating the good example set by their competitors in the zinc mining industry—for zinc has superseded copper in many articles of manufacture. Complaint is made of the high cost of intermediate crushing. For this, we believe, a remedy is forthcoming in the shape of a new crusher, which is proving to be extraordinarily effective, and cheap in its operation. One answer names the need for an improved method of removing the water in a flotation concentrate; another shows worry over the proper treatment of lean and mixed (sulphide and oxidized) ores. That is an old trouble, and is unlikely to be overcome definitely, for the better the metallurgical practice the leaner will be ore that can be beneficiated. Discontent is the penalty of progress; the progressive man is never content. The silver and lead producers are among the cheerful ones, as they ought to be, with silver at 73 and lead at 4.70. As regards lead, the outlook for American mines is excellent because no new and large deposits of lead ore have been found in foreign countries in recent years. The producers of lead, it appears, are doing nothing to promote the increased use of lead in the arts and crafts; presumably they are content with their market, although zinc paint has replaced lead paint in large measure during recent years. Electrification often involves the use of lead-covered cable, and therein lies the expectation for a largely increased consumption of both lead and copper. The zinc miner is unhappy chiefly because he has been spoiled by excessive prosperity; before the War he would not spurn the price that is now offered to him, but the high cost of living and the high cost of mining have dampened his enthusiasm for the time being. The return to the normal is slow and painful. The prosperity of the zinc miner marches with the activity of the iron and steel trades, for 60% of the zinc that is produced from American mines goes into galvanizing. Here we face the basic fact that the prosperity of one industry is dependent on that of another, as the welfare of one nation fluctuates with that of another. Interdependence is the keynote of the system of living we call civilization.

Profit-Sharing

Lack of understanding between employer and employee is usually a potent factor in causing labor troubles. A greater degree of co-operation between the various units of an organization produces better results; for then all alike become concerned with the outcome. A share in the profit of the day's work is one of the surest incentives to efficiency, economy, and the avoidance of waste; but managers have been slow to realize this important fact. The attractions of a paternalistic welfare scheme will never take the place of an additional ten dollars per week to the employee; increased effort will be made when the worker realizes that his care, his energy, and his interest have directly caused the extra profit; or, rather, they have avoided a corresponding loss to him, to his fellow-workers, and to the company. In a recent issue we drew attention to the method adopted by the Electrolytic Zinc Com-

pany, of Hobart, Tasmania, in dealing with the problem of post-war readjustment of expenses. Wages and salaries are to remain as before; but weekly deductions are to be made before payment, on a sliding scale, and ranging from $7\frac{1}{2}\%$ to $10\frac{1}{2}\%$ of the amount earned. These deductions are to be placed to the credit of a trust-fund, to be converted into shares of the company, which will be held in the names of the workmen. Another attempt at closer co-operation between employer and employee is being made at Akron, Ohio, where all the 10,000 employees of one of the largest manufacturing houses—the Firestone Tire & Rubber Company—are now stockholders. Co-operation between employer and employee is close, and every facility has been provided to permit the men to take full advantage of the profit-sharing scheme. The common stock at par is issued on terms that permit payments to extend over a period of years. The workers receive reminders, in the form of increased pay, of the beneficial effects of zeal, attention, and increased production. However, profit-sharing is not new. Mr. Samuel Cabot, in 'Co-operation' describes the results of the application of the principle at his works during the past 17 years. Every man who enters his employ, and who wishes to benefit from the profit-sharing scheme, is required to sign an agreement to the effect that, in return for the privileges accruing, he will do his work as quickly and as carefully as possible, and will give 60 days notice before leaving. At the end of each half-yearly period a definite proportion of the profits is distributed among the employees who are so entitled. The sum is divided into two equal parts in each case, one of which is given in cash to the employee, the other being deposited in a savings bank, the employer acting as trustee. The fund in the bank is in the nature of an insurance upon the life of the employee; if he dies it is handed over, with accrued interest, to his executors. In no case, however, does it return to the employer. If a workman should leave without having given the agreed notice, or if he be discharged, the money is distributed among the participants remaining at the next division of profits. In case of sickness the employee is empowered to draw upon the fund; or cash may be advanced from the balance to assist the employee in the building or the owning of a home. The result of the scheme has been a marked increase in efficiency; it has stimulated sobriety and thrift; it has assisted many to own property, thus surrounding the works with the homes of those who are financially interested in the success of the undertaking and the development of the neighborhood. Statistics show that whereas the first profit-sharing payment amounted to about 10% of the wages of the men, the most recent one represented more than 20%. In view of the increase in wages during the period over which the scheme has been in practice, the improved earning capacity of the men is a significant feature. Mr. Cabot attributes this to superior morale, coupled with greater contentment and willingness—conditions that have arisen as a result of the recognition of a mutual interest between employer and employee. Socialism and its more radical sequelae gain many adherents during

labor disputes, particularly when these are accompanied by the cessation of work, by poverty, and by idleness. In many cases this condition may be avoided by the adoption of a spirit of frank co-operation on both sides. The employer is usually in the better position to make the first move.

Revision of the Mining Law

Since the beginning of July we have published 22 letters on this subject, following the statement of the text of the proposed law in our issue of June 18. Most of the letters have come from prospectors and small operators; others in the business seem to be unwilling to endorse the proposed revision, although it is the work of a group of distinguished mining engineers, co-operating with the U. S. Bureau of Mines. The prospectors are agreed in condemning several of the new regulations, more particularly in regard to the locating of claims on cardinal lines and the connecting of them with the Public Land surveys. It is asserted that much of the public domain—the territory most likely to be prospected—is unsurveyed, and that even the surveyed portions were surveyed so long ago that in many localities the section-corners have been destroyed or obliterated, so that the prospector cannot 'tie' his claim-lines to them. As to this objection, it is usual, we believe, to comply with a similar regulation when obtaining title to agricultural land. Objection is raised to the provision for recording locations at the nearest Federal Land Office; the prospector prefers the neighborly County Recorder. The cost and delay involved in the required surveys and the verification of 'discovery' by a U. S. Deputy Mineral Surveyor are other points that provoke the prospector's irritation. He objects strongly to the clause granting an extension of time for five years on locations without discovery on the payment of \$50 per acre in lieu of assessment work, that is, at the rate of \$2000 per annum on the new 40-acre claim. This would enable rich men to hold large acreages without discovery and without doing work, while waiting for some neighbor to develop the adjacent ground to common advantage. Nor does the prospector appreciate the alternative of paying \$100 in cash in lieu of the ordinary annual assessment work, because he sees in it only so much less employment for local miners; and as for the 'development fund' into which the money goes, he fears it will be wasted in bureaucratic performances of an academic or political character. The prospector is but little concerned with the benefit supposed to accrue from the abolishment of extra-lateral rights, because the menace of litigation does not bear upon him as it does on the owner of large mines. Similarly the waiving of 'discovery' is no boon to him; he looks upon the change as an aid to the acquirement of large acreages by the capitalist. The chief objection to the 'discovery' requirement was the fact that it was too frequently evaded, dishonestly. The same criticism applies to the usual evasion of the work required annually. Both this requirement and that of 'discovery' are objectionable because they incite dishonesty—untruth in

word and in action. Any law that fosters such practices needs to be changed or abrogated. Evidently the revised law is thoroughly objectionable to the prospector and unwelcome to the small operator, but it appears to suit the mining engineer, who, one must acknowledge, looks at the matter largely from the standpoint of his client, the capitalist. Indeed, some bitterness is shown in the correspondence: the mining engineer is depicted as inimical to the prospector and small operator: one writer asserts that "the mining engineer has very nearly killed prospecting since we lost the small promoter". With this we do not agree, and we would like to publish one or two letters from representative engineers correcting this false impression. Most mining engineers are kindly disposed toward the genuine prospector: they appreciate the useful work he does and they would like to help him. It is true, however, that mining engineers, especially the leaders of the profession, are the business associates of capitalists and are retained by large companies, so that, in such a matter as the mining law, they are likely unconsciously to regard it from the point of view of their clients. Probably the proposed revision might have been more satisfactory if representatives of the prospectors and small operators had been consulted. Perhaps they were; as to that we do not know. Speaking as detached onlookers, it seems to us that the chief objection to the revision of the mining law is that it comes too late. Our mining districts are plastered with claims to which extra-lateral rights have been conceded; to introduce now a new set of claims without such rights may only increase the confusion, such as has occurred already where placer claims have come into conflict with lode claims. We welcome further discussion from mining engineers and particularly from those who took active part in framing the revised code.

Gold and Oil

Somebody once philosophized to the effect that opportunity knocks but once at any man's door. Perhaps the individual who made this observation lived in some secluded nook at a distance from the main thoroughfares of traffic, where opportunity inadvertently passed him by when making its busy rounds; or perhaps the primitive methods of travel and the general inefficiency of former days prevented opportunity from making regular and frequent calls at every man's door. In any event we insist that the theory of one visit per generation cannot apply to our own times. We have definite proof, for within the last half hour—in the last mail, to be precise—opportunity has knocked insistently at our own door, not once, but twice. First, through the medium of one Marshall Spoonts, of Fort Worth, Texas, whose "bank-book shows that in the past six months I've made over One Hundred Thousand Dollars (\$100,000) [count them] for myself", not to mention sundry fortunes that he has 'made' for his friends. Mr. Spoonts attributes his remarkable success "to this fact alone, that the man who plays the game square and always does the right thing by his friends is bound to succeed". To which we ven-

ture to remark that one way of keeping friends is to avoid giving them away. That we are fortunate enough to be numbered among Mr. Spoonts' friends is manifest from the salutation in his letter, which reads "Dear Friend". He appropriates to himself "all the honesty and integrity of a man who has led a Christian life for 43 years", and allows that he has practised the golden rule since he was four years old. We wonder if these admirable traits qualify him to induce the sands of Texas to gush their oil more voluminously or more willingly—for Mr. Spoonts' purple phrases are lubricated with Texas oil. The naive form-letter that is provided for our convenience as an investor reads as follows:

"Marshall Spoonts, Trustee,
Oil Operators Trust.

"With the understanding that you have made thousands of dollars for yourself and others off your investments in the oil business in the past few months, and will invest my money as intelligently as you would your own, I am enclosing \$..... for Interests (One dollar per Interest) in the Oil Operators Trust. I desire you to personally represent my interests in the Texas oil fields, and to invest this money for me as you would your own. It is also understood that all properties acquired by the Trust shall stand as security for my investment. I agree for you to retain half the actual net profits which you can make this money earn for me, forwarding me the other half of all net profits."

We spare the reader any further description of the entertaining literature that accompanied this generous offer, and proceed to the second enticement that opportunity put in our way. This time that other much-relished bait for the unwary—alluvial gold—formed the motif of a dissertation on a means of realizing a 'guaranteed' minimum return of \$1,000,000 by investing \$150,000, the gain being represented by 10% of the net profit. The letter of transmittal is signed by "W. E. Parker V. P.", of the Mines Operating Company, 400 Lexington Avenue, New York. The company desires to let a contract to some enterprising engineer for mining a channel of gravel 6 feet thick and 60 feet wide underlying Lightning creek in the Cariboo district of British Columbia. It is frankly stated that the "simple reason a contract proposal is made is because the previous financing and operating work was piled on one man who desires to be relieved of some of this excessive strain". Our sympathy would be more profound if the undertaking were more difficult than is indicated by this illuminating paragraph, which among other things shows what may happen when gold breaks loose:

"The object of this tunneling is to secure a lot of loose gold running at the rate of about $7\frac{1}{2}$ millions to the mile, which is mixed up through the sand and gravels which are taken out. Two miles of this same ground has already been tunneled out and 15 millions removed, of which about 90% was profit. There is about 12 millions to be removed from this mile and a half section already pre-determined, of which fully 90% will be profit. The property is now equipped for all operations with the exception of a truck, a spare or surplus turbine-pump, and small supplies and store goods."

The financing and management of such an enterprise

ought to impose little "strain" on anyone; like some other mines, it is so rich, according to the promoters, that it would be impossible to make a financial failure by mismanagement, and the few thousand dollars necessary to buy the additional equipment ought to be procurable any day from the waiters at the Waldorf. An interesting feature of the letter is a drawing showing the cross-sections of the river-channel, with its underlying clay, gravel, and bedrock; and vividly depicting mining operations. The lack of timbering makes us solicitous for the safety not only of the exceedingly diligent miners but of the frock-coated and stiff-hatted gentlemen—whom we take to be capitalists—who are gingerly inspecting the workings. We hope that the "roof" does not fall, and that the visitors are so favorably impressed with what they see that they will undertake to finance the enterprise, taking advantage of the chance that has doubtless been offered to them as well as to ourselves. However, we are not greedy, so we pass it on to our "friends", being confident that "opportunity" will call on us again.

Metric Weights and Measures

Hearings on a Bill to provide for the compulsory adoption of the metric system of weights and measures are to be conducted by a sub-committee of the Senate Committee on Manufactures. The sub-committee is to hold a limited number of hearings, so that the proponents and opponents of such legislation may have an opportunity to state their views on the subject. A stenographic record of each hearing will be circulated as soon afterward as practicable, so that the public may become acquainted with the problems involved. Later, during the regular session of Congress, it is proposed to hold further hearings; definite action may then be expected by the committee, followed by the placing of the Bill on the calendar of the Senate. If it becomes law it will provide that, after the lapse of ten years, no person shall sell anything (except for export), or charge or collect for carriage or transportation, in or according to any other than on the metric scale. The American Institute of Weights and Measures is opposed to such a change; it deplors the possibility that trade, wholesale and retail, may be conducted according to a system that is strange to our people; it contends that all postage, excises, duties, and customs charged and collected by the Government will have to be based on a standard, the units of which bear no simple or easily remembered relation to the weights and measures now in use; it emphasizes the aspect of compulsion under which the American people would be obliged to discontinue the use of the English units, in favor of "the kilometer, the hectometer, the dekameter, the centimeter, the millimeter, the kilogram, the hectogram, the dekagram, the gram, the liter, the dekaliter, the heceter, etc., etc." We are not prepared to give an unhesitating support to the Bill in question; at such a stage we are, naturally, "from Missouri"; but we consider that the Institute's arguments will serve to strengthen the position of those who are in favor of the change; for one thing, its attitude considers

the present and not the future, ourselves and not our descendants. Had it not been for the foresight and unselfishness of our ancestors a century or more ago we might today have been wasting our time and energies on a system of coinage in which four farthings equal one penny, twelve pennies equal one shilling, and 21 shillings equal one guinea. The loss of time in educational institutions in countries in which such systems are in vogue is appalling. If we considered those who will come after us we would adopt a simplified method of recording weights and measures without delay; Great Britain is waiting for the initiative of the United States in this respect.

The American Institute of Weights and Measures draws attention to the expense that would be entailed by manufacturers if the metric system were adopted. Thus, we are told, a firm in New Jersey reports that the change would involve a cost to the company of \$900,000, which, as the number of employees is 900, amounts to exactly \$1000 per worker; another firm in Michigan states that the introduction of the new standards would mean an outlay of \$3,000,000, which, distributed over 6000 employees, represents \$500 per head. Such statistics are far from convincing. Even if the figures were plausible their publication would constitute no conclusive argument against the change. The writer of these notes has lived in countries in which the metric system was unknown, in which it had been partly adopted, in which it was in use in conjunction with other units, and in which it was legally compulsory. The advantages in the complete abandonment of all other systems were obvious. When the Institute endeavors to obfuscate the issue by drawing attention to such measures as the "hectogram" and the "dekameter" it is "playing to the gallery". Intelligent Americans appreciate the simplicity of the metric system and the complexity of our own units of weights and measures; the schoolboy knows that such prefixes as milli-, centi-, and deca- are self-explanatory; if a change be made there should be no difficulty or trouble in quickly understanding the proposed alternative. American engineers, when in countries in which the metric units are used, appreciate the enormous saving of labor and calculation that results from a complete abandonment of the English system; but it must be discarded entirely; its use must be prohibited by law. The point made by the Institute that the units of the metric system bear no simple or easily remembered relation to the weights and measures now in use constitutes a feeble argument against the change; the old archaic form of reckoning should be discarded and forgotten if any change be made; other nations will soon follow suit; those who wish to preserve their connection with the unprogressive past will do so at their own loss. America faces the future; and if the introduction of the metric system of weights and measures will simplify national life for us and for our descendants, if it will decrease labor, if it will encourage accuracy, then its adoption is as certain as was the adoption of the decimal system of coinage in 1787.

Revision of the Mining Law

The Editor:

Sir—As comments on the proposed amendment and codification of the mining law are invited, you will perhaps give me space for a few suggestions and comments from the point of view of a lawyer who has seen the workings of the mining and public land laws.

The purpose of the proposed changes should be, and doubtless is, to simplify the law, to make more clear the benefits and property rights that may be acquired under it, to do away with some of the dangers and burdens to which property so acquired is exposed under the present law, and to give greater encouragement to the exploration and development of the public mineral land.

Chief among the dangers and burdens under the present law is the right to follow a vein from its apex under the surface of another, known as the law of the apex or the extra-lateral right. This right was given by the law at a time when the discovery of the vein and its pursuit into the ground were the objects of the miners; the law gave legal sanction to the customs established among them. This principle was suited to the early times and conditions—it applied to lode mining only—never to placers. As mining districts grew, however, the dangers of the system became apparent. One could seldom know with certainty whether an orebody which he had found belonged to himself or to another unless he acquired all the surrounding ground. The cost of litigation over these rights and of settlement of claims based upon them became appalling. There has been some difference of opinion among lawyers on this point—the old view still has its advocates—but I am of those who think that the greatest service a lawyer can render to his client, when an apex question seems likely to arise, is to advise him to acquire the adjoining claims or to make side-line agreements, so-called, for perpendicular boundaries. The latter is exactly what the proposed law accomplishes. It does away with the extra-lateral right wherever it is not already vested. It makes the lode claim like a placer claim; all distinction between them is done away with. This alone is so great a benefit as to make up for many minor defects in the proposed law if such there be.

As a logical outcome of that main purpose, the shape and size of claims are changed. Instead of long segments of the vein the prospector is given rectangular pieces of land conforming as far as possible with the lines of government surveys. All this is to the good.

There seems to me to be a defect in the proposed law

in that not only discovery and assessment work but even work looking to discovery may be postponed for a number of years by the mere payment of comparatively small sums of money; and lands may thus be held without any exploration or development. This is a departure from the theory that the law ought to encourage exploration and development; and there is not the excuse for it, if the extra-lateral right is abolished, that there might be under the law as it now stands. Under the present law work is required; constant exploratory work until discovery; some actual development work each year thereafter. It may be said that that requirement was often evaded and that the sure money-payment takes its place—that is true, but the law ought to require work instead of money, so that the character and value of the land can be ascertained and made the most of.

There are probably other good points and other defects in the proposed law that are obvious to the engineer or the practical miner. These are the points most obvious to the lawyer. Intelligent criticism will help the final outcome. If no particular interest is shown no law will be passed; if all those interested in mining do show an interest and commend or seek to improve it, the proposed law, or something better in some of its details, will be passed.

HENRY F. MAY.

San Francisco, October 5.

The Editor:

Sir—In discussing the revision of the mining law there is one point that, I believe, if followed up would lead to a better understanding of the question, and, perhaps, to a solution. It will be noticed that there are some cases, which nearly everyone, to some extent, seems to be aware of, to which the proposed law cannot be applied without harm. On the other hand, it will be noticed there also seem to be other cases where one feels its application, with modifications, would be beneficial. I say "feel" because we are unable to state exactly why we feel or believe as we do. It is only after considerable thought that we are able to give reasons for our belief. What we wish to discover is the distinguishing features in these two cases, with the idea of framing a law, if possible, that will cover both cases. As it is now, we are put in a position of choosing between two evils. If we choose the present law we get something that has its advantages and disadvantages; if we choose the proposed new law we get something that is an advantage in one place but a disadvantage in another.

The proposed new law would be a great disadvantage

in mining comparatively narrow veins, particularly if they have a flat dip; because it would necessitate a great amount of ground to be located—in some cases, where the vein runs diagonally across proposed divisions, ten times as much ground as the present law calls for—in order to prevent the economic unity of the vein being destroyed. In other words, the failure to do this would tend to cause the ownership of a vein to be so divided that it could not be exploited economically. This division of ownership is, also, likely to cause many trespass suits. Furthermore, making a company or an individual acquire so much surface ground, in order to mine a particular body of mineral below, makes unavailable ground that may be useful for other purposes, and may, perhaps, prevent the use of other available capital. It should be remarked that the mining of ore from a comparatively narrow vein, even if flat, in no way destroys the use of the surface for other purposes, as would be the case if the orebody was large and flat.

In the case of a large orebody, if it dipped beyond the vertical plane of its side-lines, and didn't dip very flatly, it would be a blunder to have its economic unity destroyed by a regulation like that in the proposed new law. It would certainly be wrong to run the chances of having the economic unity of a mine like the United Verde or the United Verde Extension destroyed by such a regulation.

The proposed new law should not be applied to any narrow vein—comparatively narrow vein—or to big bodies of ore where their dip is fairly steep, that is, so steep that the surface above is not likely to be disturbed by taking the ore out below. But it should be applied to large flat-lying bodies of ore, like the porphyry coppers, and to other flat-lying deposits, like those found in a limestone formation. In the case of the porphyry coppers there are three reasons why the surface above the ore should be owned and purchased by the owners of the ore. First, the mining operations are likely to spoil the surface for other purposes. Second, the orebodies being flat and so large requires the possession of the surface above them in order that the ore may be more economically mined through many different shafts distributed over the surface. Third, prospecting for the ore below is carried on easier from the surface by means of drill-holes. For this reason alone, if for no other, the ownership of the ore below and of the surface above should go together. Another reason why the proposed law, or rather a modified form of it, and not the apex law, is applicable to the porphyry coppers and similar deposits, is that the locating of claims along the edge of a flat-lying deposit as one would along the outcrop of an ordinary vein, would take in so much ground that it would hinder the discovery of other valuable mineral, and would also hinder the employment of available capital. The ownership of the surface by others would hinder prospecting. The proposed new law, with modifications, should be applied to mineral found in limestone, because the ore deposits in this formation are, as a rule, found in bunches, and, as a consequence, the discovery of them

would not be furthered if enormous areas could be easily acquired by one individual or organization, as would be the case if a stratum of limestone, in which the ore occurred, could be located like a quartz vein, and followed to any length along its dip. Such a thing would also keep a lot of available capital from being employed. There is no objection to the amount of ground an individual or a company may acquire so long as they make use of it or don't hinder others from making use of it. There is another place where the present law doesn't seem to apply. That is where a number of different veins and faults run and cross and pitch in as many different directions. As, for instance, in the Butte district.

There are two things we have to guard against: one is destroying the economic unity of an orebody, and the other is the acquisition by any person or persons of more than they have need of, or can handle. In other words, guard against any dog-in-the-manger business. The idea I wish to convey is that there are mineral deposits or veins to which the present law applies best, and other mineral deposits to which it does not apply—other mineral deposits to which the vertical side-line law applies best. Why not classify all mineral deposits and apply both laws? Classify all mineral deposits into, say, three classes. (1) Those deposits or veins to which the present law is plainly applicable. For instance, such a vein as that of the Congress mine, in Arizona, which is very regular, well-defined, and comparatively narrow, and has a dip of about 23°. (2) Those deposits to which the vertical side-line law is plainly applicable. For example, the porphyry coppers. (3) Those deposits that are on the border-line between these two. In this case it could be made optional with the locator whether he located under one class or the other. To make both forms of location equally inviting, the location calling for vertical side-lines should be made larger. By making both these forms of location equally inviting, the possibility of litigation will be the determining factor in deciding the form of location. If this is not considered satisfactory, each district could decide what form of location should prevail.

WILLIAM CROCKER.

Prescott, Arizona, October 4.

Big Bend Vein-System

The Editor:

Sir—There occurs about 16 miles above Oroville on the north fork of the Feather river a series of parallel quartz veins striking north-west, and dipping at rather flat angles to the eastward. These veins occur in both amphibolite schist and granodiorite, the latter forming the backbone of Big Bend mountain. The veins in the schist seem to be stronger and both systems carry gold and silver. The predominating minerals of the veins in the schist are pyrite, chalcopyrite, some sphalerite, traces of galena, and occasionally a little barite. Gold and silver are found wherever chalcopyrite predominates.

Oxidation and consequent 'differential enrichment' were responsible for the discovery of the so-called Sur-

cease vein, which was traced by the gold it 'threw-off' from a point at least a mile below on the river. This tracing was done, after the custom of the district, by panning. The Surcease vein was successfully mined in the oxide zone to a depth of about 50 ft. a few years ago by underhand stoping. Sulphides came in at this depth, chalcopyrite predominating, and the content in precious metals held fairly constant to the present depth of the mine, which is about 300 ft. below the first point of attack on the outcrop. Two normal faults dislocate the present ore-shoot at an interval of some 500 ft. Both faults are post-mineral.

The schist is extremely dense in its unaltered state and it is probable that the mineralization may be akin to the Mother Lode gold belt, and due to hydrothermal action, the fissure acting as the line of least resistance to ascending mineral-bearing solutions. The density of the schist has prevented dissipation of valuable mineral content by impregnation, and consequently has caused the concentration which is now the Surcease vein.

If the above be so, the vein could be expected to persist in depth. More development would be interesting. I submit the above brief personal deductions in the hope that other engineers who know the property may voice their opinions as to this line of reasoning and consequent possibilities of this district.

ROBERT J. BURGESS.

Tuolumne, California, September 28.

A Milling Method

The Editor:

Sir—A novel treatment is being given the gold-silver ore of the Juniper mine, at Hayden Hill, California, and a short description of it may be of interest to your readers. The gold and silver are found in veins of rhyolite that intrude through rhyolite-breccia. The precious metals are in a detached condition, that is, they are not affixed to the vein-matter but are retained in the cleavages of the rock by a clayey material of which the veins are partly composed.

The ore as broken in the mine is delivered through an inclined shaft to a pocket at the surface. In this pocket a grizzly has been placed, to discard as waste all material larger than 10 in. diam., the finer material being trammed to the mill. Above the mill-bin is another grizzly, which allows all material finer than 6 in. diam. to pass to the bin, the remainder going to a jaw-crusher, which reduces it to less than 6 in. From the mill-bin the ore is fed, by a Challenge feeder and belt-conveyor, to a trommel 16 ft. long and with a diameter of 40 in., having 1-in. openings, and revolving at 18 r.p.m. The trommel has internal sprays distributed throughout almost its entire length.

The plus 1-in. portion of the ore, after passing through the trommel and being washed by the sprays, is discarded as waste. The minus 1-in. portion is conveyed by a drag-belt to two 5-stamp batteries, the surplus from sprays furnishing the water for the batteries, where it is crushed to pass a 20-mesh screen; after which it passes

over amalgamating-tables, one for each battery, 3 ft. long by 5 ft. wide. The rest of the amalgamating-tables, 12 ft. long by 5 ft. wide, is covered with two equal lengths of brussels carpet, having a drop of $\frac{1}{2}$ in. between them and $\frac{1}{2}$ in. between the plate and the carpet. The bed, or table, is inclined at about one inch per foot. The carpets are removed at two-hour intervals, washed, and returned to the tables. The product resulting from cleaning the carpets is placed in a clean-up barrel with mercury and other chemicals, the barrel revolved at 20 r.p.m. for four or more hours, when the gangue-material is washed over a jig, the amalgam separated and collected. The tailing, after passing over the carpet, is pumped to a hydraulic amalgam-trap, from which it goes to a 24 by 8 ft. Dorr thickener. A diaphragm-pump passes the thickened tailing to a waste-pond. The overflow is returned to the battery-tank, to be used over again through the trommel-sprays. In this manner about 60% of the material sent to the mill, assaying about \$25 per ton, is rejected from the trommel. This reject assays 60c. per ton. The tailing from the remaining 40%, after amalgamation and carpet treatment, assays from 80c. to \$1.20 per ton.

In submitting the above I make no claim of having put into operation any new method, but as the combination has proved a great success on the treatment of this particular ore it may be possible that others may find it useful.

G. W. GILMAN.

Hayden Hill, California, September 26.

To Help the Prospector

The Editor:

Sir—Some time ago I observed in your paper a reference to the subject of how to revive prospecting. In all that was said there was much of interest, but no remedy was forthcoming that would serve the purpose of reviving interest as in previous times, for, in the end, the prospector, who must assume all the obligations attached to his business, and is only successful by virtue mainly of his limited resources, soon finds himself unable to pursue his business to a fortunate conclusion. One of the most discouraging features of the life of a prospector is that it often happens that he makes what he feels will prove to be a favorable find at a time when his last pot of beans may be on the fire, and he is then obliged to seek work, perhaps at some mine many miles away or at some other remote place until such time as he may be able to gather enough together to resume his prospecting. In the meantime, his location, by reason of the lapse of a few months since he was upon the ground last, has been forfeited to someone else, who now also may be in temporary possession—perhaps another prospector like himself.

The reason that causes this prospector to lose his rights to the ground, which had cost him many days of hardship to find, was the lack of capital to complete his work properly, as it should be done. Just how many are the favorable prospects that are now awaiting development

because of the lack of a little money on the part of the prospector—who may only need assistance to the extent of sinking or driving a few feet to make his prospect attractive to capital—no one but the prospector himself will ever know, for he has long since learned to conceal such finds as he makes in his wanderings, knowing as he does how unfruitful any efforts he could make to interest anyone would be, because of the lack of interest that people in general show toward him and that of the business that he follows—all because it is not founded upon or built upon a substantial business basis. Who, then, is at fault, and what is to be the remedy? Something must be done to stimulate prospecting, or in a few years hence there will be few mines in process of development to take the place of those becoming depleted of their ore-reserves. This is a matter of grave concern to the general welfare of the country, as will be admitted.

We have many provisions in our laws to protect the Government, but few, if any, to encourage the business of prospecting. All our mining laws provide adequately for the protection of the Government in forfeiture clauses, but nowhere is there any provision made to protect the pioneer in his work against ultimate loss, as it is customary to recognize and provide for in any other line of business or pursuit. If, perchance, as only too often happens, the prospector may be financially embarrassed, he must suffer his claims to be lost to him with no reward or re-payment in any way to come to him for his work. After the expenditure of his means and energy, not infrequently having lost his health and may-be in the later part of life, he can look back upon his efforts, in their having first brought to light some pay-streak or showing that later others having acquired, when he was obliged to quit, had developed into a property of value. He had in his pioneer work led the way, but reaped no reward, which all will acknowledge, is decidedly wrong, in justice, and should be corrected.

The Government had in mind the protection of investors in the development of its public lands when, in the Carey Act, it incorporated certain provisions (see page 50, Document No. 547, Public Land Statutes of the U. S.) providing that "a lien or liens is hereby authorized to be created by the State to which such lands are granted, and by no other authority whatever, and when created shall be valid on and against the separate legal subdivisions of land reclaimed, for the actual cost and necessary expenses of reclamation until disposed of to actual settlers". As a further citation of this same attitude toward the investor on the part of the Government, it is noted (page 289, above mentioned document), referring to canals, ditches, and reservoirs (Sec. 20), "that the provisions of this Act shall apply to all canals, ditches, or reservoirs hertofore or hereafter constructed by corporations, individuals, or associations of individuals, on the filing of certificates and maps herein provided for. If such ditch, canal, or reservoir has been or shall be constructed by an individual or association of individuals, it shall be sufficient for such individual or association of individuals to file with the Secretary of the

Interior and with the registrar of the Land Office where said land is located a map of the line of such canal, ditch, or reservoir, as in case of a corporation, with the name of the individual owner or owners thereof, together with the articles of association, if any there be. Plats heretofore filed shall have the benefits of this act from the date of filing, as though filed under it; provided, that if any section of said canal or ditch shall not be completed within five years after the location of said section the rights herein granted shall be forfeited as to any uncompleted section of said canal, ditch, or reservoir, to the extent that the same is not completed at the date of the forfeiture".

In so much as the prospector and miner are engaged in the development of the resources of the country, spending their time and money and thereby acting in as good faith as the party or persons developing the farming lands, there appears to be every reason why he should have the same consideration as those who are protected against ultimate loss by the Government in the manner as above outlined. It would seem as though this was something that was his due and but a matter of justice, that he should have the same benefits accrue to him as those provided for him who prepares lands for farming in advance of their producing crops. I am inclined to the view that it is no fault of the legislative branch of the Government that some such provision has not long since been made, but may perhaps be attributed to a lack of proper consideration and study being given this matter by those who are in power. It is perhaps something that has been overlooked, but should be overlooked no longer, for there is need for some early and specific action, and I believe that it is a matter that would have the support of everyone familiar with this phase of the prospector's lot in life and that of the mining industry, which is indebted to his perspicacity for what it is today.

Were some such provision made, it would give the prospector and pioneer in mining a lien upon the ground that he locates upon the public domain for all the money and time that he might expend in its development, filing a lien in somewhat the same manner as that now in practice with the development of land, at the nearest Land Office, and having this a matter so recorded that in the event he was unable to go on with his development and the land were to be located by someone else, this lien would be entitled to first consideration whenever the mine became a producing property and returning to its owners any revenue with which such claims as this and any other of a similar character, made by other prospectors or miners, in the order in which they became possessors by location, should be paid.

If some such provision as this were to be made, no doubt there are many prospectors and mine-owners, who, feeling that they cannot personally command means to proceed with the development work necessary, or, who for any other reason are unable to explore their mining claims, would elect to make the filing that would be required for their protection with the local Land Office and

retire. I fancy that there are many old-time prospectors who would welcome such a chance, that would relieve them from being burdened in their remaining days with the annual assessment work, by being now able to have this feature finally disposed of, as an obligation that would no longer be required to safeguard their rights. The U. S. Land Office may thus be made to serve the purpose of a clearing-house, because of the great number of relinquishments and filings that would be made by those interested in the development of the promising prospects and mining claims of the country. Surely it would appear that investors would be greatly interested in learning at the respective land offices as to what there may be open to them for investigation and location in the way of prospects that have been already discovered and somewhat developed. This suggests that because of this increased interest and the development work that would in a great many instances follow, the mining regions would profit greatly, where now little or nothing is being done. The prospector or mine-owner would always possess the advantage of giving up a portion of his holdings by the filing of relinquishments and retaining those which he may be able to do his development work upon, instead of relying entirely upon himself, and as often happens being obliged to develop a district alone. His relinquishments would attract others to come to his aid in the development of such claims; this incidentally would make the holdings that he had retained more valuable. Finally, it is well to emphasize, there remains an insurance to the man who had the courage and pluck to give his time and money freely in the early development, with the assurance that, if ever such prospects may prove to possess value and develop into paying mines, he at least will be paid something for his expenditure of time and money in its initial stages of development. As a lien-holder, he has this guarantee, which is never to be lost to him, because he may for some reason or other be obliged to forfeit his right to the claim he owned. If his own energy, purse, and resources proved inadequate to ensure the success of his own efforts, he still has the lien as an asset that in the end will reimburse him.

As to the business features involved, the position of the prospector, in his ability to interest men of means in his prospecting and development work is greatly improved. If the man who first initiates the discovery work and those following him in the execution of development work, each in turn, would find it possible to be protected as outlined, then the business of each would become more stabilized, and, as a result, investors would be more disposed to extend financial aid as needed. With such a lien on file, the prospector's title would be materially benefited, it would be a great protection to him as against those designing to secure his locations without reimbursing him for such, and, whenever it came time to secure U. S. patents for his claims, his abstract of title would be somewhat simplified, better defined, and as a consequence command greater respect for final certification at the hands of the Government officials having the case in charge. Such patents, of course, would be secured in

the regular way, by the payment of fees and the regulation price for mineral lands as now provided. The prospector or miner who proposes to hold onto his lands need be in no way interfered with, for he need not file his form of relinquishment until he decides to abandon his claim, and even then he may not be obliged to do so, unless it appeals to him that by so doing he will be aiding himself directly by virtue of this act inviting others to investigate the merits of his former claims, which, if they decide to re-locate and develop cannot but prove to his advantage in re-payment, as stated above, of the outlay he has made upon such.

In the filing of any relinquishment, the owner should be permitted, if he so choose, which I think he would be glad to do, to file with the U. S. Land Office a brief statement as to the nature of his discovery, and any information relating thereto that would be of interest. He might also give his permanent address, so that persons desiring to consult with him, with respect to such finds as he may have made, while the property was his, may do so. In this manner a prospector could give information to a re-locator that he would prefer not to embrace in the brief statement he would file with the Land Office. With such statements on file at the Land Office the prospector would be greatly benefited, for he would be able to find records of much value, which could be consulted, wherein, frequently, he would find it possible to save himself much time and expense in avoiding a needless duplication of work and expense.

JOHN T. REID.

Lovelock, Nevada, October 3.

Valuation of Placer Deposits

The Editor:

Sir—I would like to call attention to a point in connection with the valuation of placers, which, if true, explains some of the discrepancies between sampling estimates and actual recoveries, of which Mr. Gerald H. Hutton speaks in his article, 'Valuation of Placer Deposits'.

These discrepancies, I believe, to a great extent are due to a peaking or a ridging of high values, which, in all probability, occurs in every valuation of a placer deposit. That is to say, instead of the value of ground between holes gradually changing between high- and low-grade holes, as per theory (according to which the value of ground gradually changes between holes), the value of the ground falls off sharply near high-grade ground; and the farther away, the less rapidly the values fall.

I know of no facts or experiments that prove, directly, that this is the case; I base my opinion on theory, and on the ground that such a peaking or ridging explains the great discrepancies noted by Mr. Hutton.

I remember reading in the fore part of Le Conte's 'Geology' the statement that the carrying power of water varies as the sixth power of the velocity. This, I believe, would cause a peaking or ridging of high values. A slight change in the velocity of the water would make a comparatively great change in its carrying power. A de-

crease to one-half the velocity would cause the carrying power to drop to $1/64$. Along any dry creek-bed one can see the evidence of this abrupt change in carrying power. What we know happens to gravel, happens also to gold. Small pieces of gold (not flake gold) are affected in moving water much the same as is coarse gravel, and will, most likely, be deposited near it. That is, the ratio between the surface and weight of small pieces of gold is approximately the same as the ratio between the surface and the weight of coarse gravel; it will, therefore, be affected much the same in moving water. In dry creek-beds one can often notice the way the coarse gravel piles up. So it is likely the coarse gold does the same.

To avoid over-estimation, on account of this peaking or ridging effect, the best practice would seem to be a closer spacing of holes around extremely high-grade holes.

WM. CROCKER.

Prescott, Arizona, September 16.

Valuing Partly Exhausted Mines

The Editor:

Sir—In your issue of March 19 appeared an article by Morton Webber in which was discussed the valuation of closed mines, either caved or flooded. While agreeing with the ideas there presented and deeming it unnecessary to call further attention to the excellence of his presentation, I wish to point out some false assumptions that were made in the period of initial risk. On page 389, Example B shows a longitudinal projection of an ore-shoot having an hour-glass shape. The pitch of the shoot is approximately 45° . Below the middle of the hour-glass are four levels, the 800-ft. level being the lowest opened. The length of the drift in ore is greater than on any level above. Mr. Webber says: “The 800-ft. level was re-opened and the floor sampled. At this stage the gamble looked attractive, for, among other features, *the ore-shoot seemed longer than on any level above*. The information of the 900-ft. level was then not known. This should be understood to appreciate the situation as of that time. *There was nothing to show that the pitch of the ore-shoot was flattening*, and that the increased length of the level was due to the fact that the plane of the level was approaching the major axis of the shoot. All the levels above the 800-ft. level were caved”. The italics are mine.

I do not see how one can assume logically that the increased length of the 800-ft. level in ore in any way indicated that the width of the ore-shoot was at a maximum there. Mr. Webber shows that it was known that the ore-shoot had narrowed at *A-B*. A line *X-Y* drawn from the mid-point of this narrow portion to the mid-point of ore on the 800 and another line *C-D* drawn normal to it from the 800 station would have prepared the way for a more logical estimate of the probable extension of the shoot. Regardless of flattening pitch, one might reasonably assume that as much ore would be found below *C-D* as between *A-B* and *C-D*; and one could not wisely assume any greater volume as probable.

The initial risk of the 900 was perhaps justified, but the point I wish to make clear is that the assumptions I have italicized were not reasonable or natural at the time they were made. The results of the development on the 900 should have been foreseen, at least as an extremely probable alternative to increasing width of ore. It seems to me that there were only two logical assumptions possible: one that *C-D* was the maximum width of shoot, the other that a line through *K* parallel to *C-D* might be longer and prove the shoot to be widening. Safety would suggest the first of the two. In other words, the chances were assumed to be favorable when it should have been recognized that there was an equal chance that the greatest width of ore had been passed in the upper levels. The length of drift in ore on the 800, in fact, was no measure of the width of the ore-shoot.

The 900-ft. level should have been driven with the purpose of ascertaining whether the major width had been passed. As soon as it had advanced, say half-way, the balance would have been thrown in favor of the assumption that the shoot was a lens of diminishing width.

It will be noted that the amount of ore actually found below the line *C-D* proved an apt illustration of the principle that in an ore-shoot of the type indicated between *C-D* and the surface, if a line be drawn normal to the pitch of the shoot from the point where ore is cut on the foot-wall on the lowest level, one may reasonably assume that as much ore will be found below this line as has been taken out above it, when this line is longer than similar lines on upper levels. Provided also there be no indications of drastic geological changes, which, I take it, there were not in this instance.

This article of Mr. Webber's has been subjected to critical examination in a class of senior mining students under my direction and has been most valuable to these budding engineers. May we have many more as well written and so full of sane reasoning on this most difficult and at times most trying phase of mine valuation.

L. O. HOWARD.

Pullman, Washington, October 2.

Pulverizing Coal for Use in Smelting

The Editor:

Sir—I was very much interested in reading the article by Mr. Arthur B. Parsons in your issue of September 17 covering the smelter of the Nevada Consolidated Copper Company.

This article is complete and, in view of the intimate knowledge which I have of the plant, true to the conditions existing. I feel that the ‘Press’ is entitled to congratulation upon the accuracy of this report.

In the description of the Roasting Department, on page 395, paragraphs 2, 3, and 4, I wish to add that in January 1918 I took out Patent No. 1,251,692 covering this device and that therefore the special features of the same are protected by this patent.

R. E. H. POMEROY.

Canton, Ohio, October 5.

FIG. 1. GOLD-DREDGE IN OPERATION

Shop-Operations and Repairs on Gold-Dredges

By Frank A. Stanley

*The recovery of placer-gold through the medium of the dredging process is one of the most striking engineering operations that may be seen in California and in other far Western States. Something like one hundred million dollars in gold has been recovered in this manner during the past 20 years in California alone, and it is estimated that the dredges employed in the work have handled about seven hundred million cubic yards of gravel during that period. These dredges, costing in modern designs up to half a million dollars or more, are remarkable pieces of mechanical equipment; obviously there is much of interest to be found in the methods of construction, operation, and upkeep.

Typical views of gold-dredges in operation are presented herewith in Fig. 1 and 2; the former shows a complete side-view of a dredge at work in the pond, whereas Fig. 2 illustrates the appearance as seen from the ladder-end with the long train of heavy buckets coming out of the water and passing up into the housing of the dredge.

The illustrations that follow show features of the shop practice of the Natomas Company of California in

connection with the making of new parts for dredges and the repair of old parts at the company's plant at Natoma near Folsom.

OPERATIONS ON LADDER-ROLLERS. Fig. 3 illustrates the method of boring out the shaft fit in cast-steel ladder-rollers. These rollers serve as idlers over which the buckets pass as they emerge from the pond; their positions on the ladder may be seen upon reference to Fig. 1. Like other of the moving parts these rollers are subjected to extremely severe conditions of service and they are mounted upon their shafts under heavy pressure. The shaft takes a bearing near each end of the roller; the operation of boring out the metal is similar to the sizing of a hole in any long hub where clearance is provided along the middle of the length of bore.

A typical roller has an external diameter of 16 in., and a face length or width of 4 ft. 1 in. The shaft is 5 in. diam. and in machining it allowance is made for forcing it into the roller under a pressure of 20 tons per inch of diameter or a total pressure of 100 tons. This pressure per inch of diameter is not far from double that commonly allowed in railroad shops in pressing locomotive drivers and axles together.

*Abstracted from 'Western Machinery World', July 1921.

The method of boring the rollers requires little description. The work is mounted as in Fig. 3, in V-blocks upon the table of the horizontal boring machine and secured by V-shaped clamps over the top of the roller.

FIG. 2. VIEW OF GOLD-DREDGE BUCKETS

of the dredge, and will range up to over 7 in. diameter for the biggest dredges. There are 80 to 100 buckets on the big dredges and one pin to each bucket. The buckets work to a maximum depth of 80 ft. or more, encountering hard bed-rock reefs and boulders of all sizes. Consequently the pins which take the load of the operation are subject to severe conditions.

These pins are forged from chrome-vanadium steel,

FIG. 3. BORING LADDER-ROLLERS

work properly centred the cutter-bar is fed through to size the bore to the specified dimensions.

BUCKET-PINS. Another part subjected to wear is the bucket-pin, several of which will be noticed in Fig. 4. These pins are made in various sizes according to the size

and are machined to proper size of body and head. They are heat-treated, oil-tempered, and given the Brinell test for hardness. A record is kept of the time each pin is made and put into service. The record gives the serial number of the pin, the temperature under which it is

FIG. 4. DRILLING A BUCKET-PIN

FIG. 5. HEAVY PINION ON PLANER FOR CUTTING KEY-WAY

handled in the furnace as recorded by a pyrometer, and the Brinell hardness number.

The operation shown in Fig. 4 is the drilling of the head of the pin. This is accomplished by strapping the pins vertically to the side of the table of the radial drill

bore and is keyed in addition. The steel casting weighs many tons and of itself is a heavy load on the shaft. The latter is a special steel hollow-forged member ranging up to a maximum of 25 in. diam. at the fit in the bore. The pull of the long bucket-lines comes on this tumbler and shaft; the extreme loads, and constant shock and vibration may lead eventually to a cracked shaft even where the dimensions are as liberal as noted above.

THE LOWER TUMBLER. Much use is made of the oxy-acetylene welding- and cutting-torch in dredge repairs. An operation on a lower tumbler with the cutting-torch is illustrated in Fig. 7. Owing to the drag of the long heavy line of buckets over this lower tumbler the surface wear is marked, particularly along the inner faces of the flanges which take the side-thrust of the bucket-line. The position of this tumbler will be noted at the extreme right of the dredge illustrated in Fig. 8.

The lower tumbler is a manga-

FIG. 6. UPPER TUMBLER ON 25-IN. SHAFT

where two pins can be conveniently secured by one strap.

OTHER SHOP WORK. There are various heavy gears and pinions in the equipment of dredges and a shop operation on a coarse-pitch pinion is shown by Fig. 5. This represents the method of cutting key-ways in the neck of the pinion. The work is blocked-up on the platen of the planer and secured to the face of an angle-iron by straps at each side as indicated. The back end of the key-way of course has been drilled out in a previous operation to allow the planer-tool sufficient space to run out in its cut. In this instance two key-ways are cut 90° apart on the hub.

The broad nose, flat-ended gripping tongs suspended from the chain-hoist provide a handy means for picking up work of this character for placing in position for machining or for removing from the planer when finished.

THE UPPER TUMBLER. The buckets are operated over an upper tumbler which, in one form, is shown in Fig. 6. In some designs the tumbler and shaft are cast integrally. In this instance the shaft is a press-fit in the tumbler-

FIG. 7. CUTTING RIVET-HOLES IN A MANGANESE-STEEL TUMBLER WITH AN OXY-ACETYLENE TORCH

nese-steel casting, very expensive to begin with, but endowed with long life through its original toughness and strength. The use of the cutting-torch in reinforcing such worn surfaces as occur along the inner faces of the flanges has been effective in greatly lengthening the period of service. In Fig. 7 the workman is shown cutting holes through the flanges so that reinforcing sections

FIG. 8. DREDGE WITH LADDER RAISED TO SHOW LOWER TIMBLER

can be riveted in place. These flange sections are of manganese-steel and their shape can be noted from the lower sections which have already been placed in position. The sections are used as templates for determining the positions for the holes to be cut with the torch. The operation of 'drilling' in this manner required but a short time for an entire series of rivet holes around the flange.

The acetylene outfit used about the yard for this purpose is a portable affair which is readily moved from point to point wherever required.

A bucket-idler of large diameter is shown in Fig. 9.

BUCKET WORK. The use of the oxy-acetylene torch is further illustrated in Fig. 10 in connection with work on the buckets. These buckets, made in two pieces, carry a manganese-steel lip which is riveted in position as in the manner shown by the buckets that appear in the background of the picture. When the lips become worn they can be removed readily by applying the torch to the rivet heads. Or again, in fitting up buckets and lips the torch is used as in Fig. 10 for cutting the rivet-holes through the metal.

Status of the Metal Mining Industry: An Interrogatory—III

LEAD

Question 1: Is lead mining recovering by means of the general lowering of the cost of production?

"Silver and lead mining are recovering, due to lowered cost of production, lower cost of supplies, and a reduction in labor costs, together with more efficient labor."

"Unfortunately, I am not at this moment in close touch with the lead mining situation. I am rather looking on from the side lines, and so do not know as yet whether lead mining is improving or not. So far as concerns those few mines with which I have immediate connection, there has been very little betterment, and yet I feel there is a betterment; and the situation is improving."

"Not yet."

Question 2: What particular factors will influence a return of better prices for lead?

"I hardly imagine we are likely to see very much better prices for lead. My own thought is that we in the United States will have to compete with the people of Europe, particularly the Germans and those people living in old Austria, who produced some of the lead. They are producing at a very low cost in dollars because their own currency is so very much depreciated. For a time we will have to meet that competition, and while the total amount of metal they produce is not very great, it is sufficient to affect the price."

"My thought is that as we have already come back to almost 1913 prices in a large number of articles, we will have to expect that lead too will have to stay at about that pre-war price, and if I remember correctly the pre-war price of lead was somewhere between \$4 and \$5 a hundred pounds, generally nearer the lower figure. The figures on the following table were taken from the Journal of Commerce of August 23rd and purport to be price indexes as recently compiled by the Harvard Committee on Economic Research:

(Average for 1913 = 100)

Corn	106	Zinc	73
Wheat	156	Coal	231
Flour	144	Coke	120
Cotton	94	Petroleum	94
Wool	113	Cotton goods	163
Tobacco	78	Silk	162
Sugar	155	Rubber	18
Cattle	99	Hides	71
Hogs	111	Calfskins	90
Pig iron	126	Leather	122
Steel billets	122	Brick	218
Copper	79	Lumber	161
Lead	103		
Tin	62	Average	117

"An organized effort by producers for increased consumption would influence the price of lead for the better."

"Proposed duty to keep out the foreign lead. Increased demand for lead products."

Question 3: What are the lead producers doing individually or collectively to promote the increased use of lead in the arts and crafts?

"Not to my knowledge are producers doing anything, either individually or collectively, to promote the increased use of lead."

"I know of nothing that is being done by lead producers to promote the increased use of lead in the arts and crafts."

"Nothing that I know of."

Question 4: Are the managers of existing properties considering ways and means of reducing operating costs through the installation of more modern and more economical equipment? Please give such particulars as you can.

"At all times alert managers are on the look-out for, and making tests on, more modern and economical equipment with a view of reducing operating costs at all times. By the installation of electric haulage; underground telephones; electric power for hoists and compressors; better ventilation underground; carriages and haulage underground for the use of the men to and from the working places."

"Managers of existing properties have always been considering ways and means of reducing operating costs, and without doubt they are continuing that same program even more strenuously now than ever before."

"Managers of existing properties are considering ways and means of reducing operating cost, but there is no strikingly advantageous or economical equipment that has not already been used."

Question 5: Is there a tendency to substitute mechanical for hand labor wherever possible, and for what particular class of work?

"Yes; replacing hand drilling throughout stopes by air drills; electric haulage; delivery of supplies and tools at convenient places underground."

"There is a tendency everywhere to substitute mechanical for hand labor. This tendency has been increased, due to the high labor cost, and will be still further increased when the cost of well-known mechanical appliances is reduced."

ZINC

Question 1: Is zinc mining recovering by reason of the general lowering of the cost of production?

"I would say 'No' to this question, as with zinc in quantities adequate to meet current demand, selling on the average for say 20% below the bare operating cost of production, the lowering of costs can have practically no bearing on the quantity of zinc produced. The lowering of costs is, however, the only thing that has prevented production at present prices from being absolutely ruinous."

"Up to the present time, so far as we are concerned, there has been no recovery due to the general lowering of the cost of production."

"I do not see any sign at the present time of a recovery, although I believe we will shortly have a recovery. The cost of production has been lowered and is about as low as it can be for the present production. Any increase in production must come from an increased demand and higher prices."

"The zinc properties that are operating today have, as a rule, been successful in reducing their costs from 25% to 50% below what they were a year ago. This reduction has been principally in labor and powder and there are other reductions being made at this time on steel products and other necessary mining repairs and supplies which are helping to gradually reduce costs. The increased efficiency in labor is responsible to a great extent in reducing mining costs. In our case, for instance at —, our underground efficiency is 100% better than it was a year ago and the men that are working seem to be contented and are putting forth their best efforts to help reduce costs in every direction."

Question 2: What particular factors will influence a return of better prices for zinc?

"The most important factor is the increased consumption of zinc. Consumption at present is only at the rate of approximately 150,000 tons per annum as against a normal rate of 350,000 to 400,000 tons. This improvement will occur in all probability when steel prices become stabilized and output increases again, as about 60% of the zinc output goes into galvanizing. An improvement in the brass industry, and absorption of scrap war brass, would also materially assist, as about 20% ordinarily goes into brass."

"Restriction of zinc output until stocks have been re-

duced to a reasonable amount, say 30,000-40,000 tons as against actual stocks now of about 95,000 tons, and thereafter adjustment of production to meet consumption."

"Increased consumption with the necessary protection against imports."

"As you know, all metals are at a standstill and this is noted particularly in regard to iron and steel. The world cannot go on without going back in our civilization with the present production and undoubtedly as stocks decrease we will have to go back to a larger production. In zinc the production before the war was about one million tons. The present production is not over four hundred thousand tons. Clearly, unless we are to go back in our civilization, we will have to return to the million tons or more. This can only be brought about by an advance in prices."

"Of course, a general business improvement in all lines will effect zinc but in my opinion the particular factors that would have the most influence on a return of better zinc prices is the increase in manufacture of galvanized sheets and corrugated zinc sheets. On account of inferior galvanizing that was used during the war, it is necessary to a great extent to re-establish our galvanizing trade in foreign countries and at such time as we are again making a first-class sheet and there is any demand for galvanized products, a very large percentage of the domestic production will be consumed through that channel."

Question 3: What has been the effect of the campaign of publicity upon the demand for zinc and zinc production? Has it paid?

"We assume you refer in this connection to the activities of the American Zinc Institute. These efforts have been devoted almost entirely to increasing the uses of sheet zinc, and as we are not producers of sheet zinc, we feel that the answer to this question should come from those who are."

"Not in a position to form an opinion as to whether the campaign of publicity has helped any or not."

"No doubt the campaign of publicity has done good, but it is very clear that the growth of added uses would at best be slow and could not have an immediate effect. When we consider the world's pre-war consumption of one million tons it is quite apparent that none of the new uses suggested could at once be appreciable. No doubt in its broadest sense this publicity has paid, but planting the seed is always expensive and bring no immediate returns."

"I believe that the campaign of publicity for the new uses of zinc has helped. The zinc shingle has been

brought to the attention of the public and I am informed the demand for same is gradually increasing. As soon as there is a revival in building it is my opinion the demand for zinc roofing will be fairly good."

Question 4: Are the managers of existing properties considering ways and means of reducing operating costs through the installation of more modern and more economical equipment? If so, please give such particulars as you can.

"As we are both miners and smelters, we will answer your question from our own standpoint in two parts:

"1.—As regards mining and milling, we believe our equipment is up to date in every respect, and we do not know of any equipment we could install that would be more modern or to any material degree more economical than what we now have.

"2.—As regards smelting, no radical changes are in prospect.

"We do not know whether your question is intended to cover such changes as would amount to the substitution of new processes for old, or whether it refers merely to improvements in existing processes by installation of more modern equipment.

"In the former case, we feel no radical changes are in prospect. Our active smelting equipment consists of two producer-gas-fired retort-plants with sulphuric acid works. We feel that the retort zinc-smelters of the United States, particularly those using coal, have been placed at a great disadvantage over the past few years in comparison with other processes using less labor or less coal than the coal smelter does; but with wages back to pre-war, as apparently they are destined to go, and lower priced coal, which will probably be obtainable upon the negotiation of a new wage contract with the coal miners after March 31st, 1922, it is our belief that the producer-gas-fired-retort zinc-smelters will assert their superiority as of old in the production of zinc from ores that do not contain valuable by-products for the recovery of which the coal zinc-smelter is not well adapted. As the major supply of zinc ore is apparently to come for many years from the Missouri-Oklahoma-Kansas field, and does not contain precious metal values, it is our belief that no 'modern' equipment is likely to take the place of that already available and in use.

"In the latter case, we believe there may be some improvements in roasting through the adaptation of continuous-roasting furnaces, such as the Wedge, to the dead-roasting of zinc ore, which has heretofore had to be performed in Hegeler furnaces, if sulphuric acid was made from the sulphur expelled."

"Believe where there is room for more modern and economical equipment, all managers are giving this necessary consideration."

"No doubt the managers are improving practice, but I have not noticed any radical or sudden changes."

"Account of abundant supply of labor at low prices do not believe there is much attention being given at present to installation of labor saving equipment in mines. There have been installed during the past two years a number of mechanical shovels but inasmuch as now hand shoveling costs less than mechanical shoveling the majority of this equipment is idle.

"During the war there was developed in the — district one of the richest deposits of zinc that has been known to date and this district is now producing at an operating profit as much zinc as they were producing during normal times in 1912, 1913, and 1914 and selling same at from \$20 to \$30 per ton. On account of the development of this rich deposit the price of zinc concentrates will no doubt be low over a period of years and with ore at this price the smelting industry would be a profitable game if metal were selling at around 5c."

Question 5: What class of mining, milling, and smelting machinery is least satisfactory in performance of its function, and in what respects should it be improved?

"This question is entirely too broad to be answered briefly."

"This would largely be a local question, although many lines might be suggested."

Question 6: Is there a tendency to substitute mechanical for hand labor wherever possible, and for what particular class of work?

"In mining, as you probably know, the scarcity and inefficiency of labor over the past few years compelled the adoption of mechanical means for loading ore. Since wages have been generally reduced, and labor has again become much more efficient, the mechanical substitutes to quite a large extent have been abandoned. In smelting there is at present no tendency in this direction."

"Think there has always been a tendency to substitute mechanical for hand labor where possible. However, it will be appreciated it has its limitations in mining."

"There are many suggestions, perhaps the most prominent being mechanical haulage and loading, although not much progress is being made in this respect. During the war some progress was made due to high wages more than anything else, but with a lowering of wages the problem does not look as attractive.

"On the whole I do not see much hope, except by the ending of the present stagnation which I believe to be only a matter of a short time. At the present time Joplin is only producing at a rate of less than 150,000 tons of metallic zinc. Wisconsin is practically closed. I am not so familiar with the Western conditions, but I doubt whether all of these including the Eastern fields are producing at the rate of over 25,000 tons and certainly the

whole United States is less than 200,000 tons. Of course, in these figures I have omitted all question of ore raised for oxide purposes, as metallic zinc could not be produced from such ores. Outside of the United States it is not likely at the present time that the production is over 200,000 tons, which would give a total of less than 400,000 tons for the world's supply, as against one million tons in pre-war years. The natural growth of civilization would call for an increasing consumption of zinc. A demand which has a growth from a few thousand tons to a million in 50 years can not drop back to 400,000 tons without a serious derangement of our industries. I see no way of increasing our present production throughout the world without considerable advance in the price of the metal."

Zirconium

On account of various mysterious properties and uses that have been attributed in the popular mind to zirconium, it has at times been styled 'the mystery metal', says the U. S. Bureau of Mines. The compounds of zirconium have numerous important uses, and more doubtless will be found. Investigations have indicated that sintered or coherent zirconium metal is resistive to acids; it can be used for electrodes, and it probably will find a use in metallurgy. A steel-zirconium has been proposed for use in armor plate and automobile parts; nickel-zirconium alloys have been suggested for high-speed cutting-tools and for cutlery. Zirconium oxide is recommended as a refractory, as an abrasive, as a pigment in paints, and as an opaquing agent in enamelware. The salts have been used in the textile industry as a mordant or for the fixing of dye, and also for weighting silk. Zirkite firebrick is used for lining furnaces, as well as for other purposes where a refractory having a low coefficient of expansion, high melting point, and maximum resistance to slag corrosion is demanded. Although zirconium oxide has not proved satisfactory for gas-mantles or for arc-lamps, it has been used for making polishing powders, insulators for both heat and electricity, and in the Nernst lamp. Being non-poisonous, zirconium oxide is finding a use in paints and lacquers, where its resistivity to physical and chemical agents is proving highly valuable. As an abrasive, zirconia, zirconium silicide, and zirconium carbide are suggested for a variety of uses, the carbide particularly as a substitute for the diamond in cutting glass. Zirconium oxide, because of its non-toxic nature, is used in place of bismuth nitrate or carbonate in Röntgen-therapy. It is also said to have medicinal value. Zirconium oxide and nitrate have been suggested for use in the extraction of oxygen and nitrogen from the air. The oxide may find use as a filler in the manufacture of rubber goods. In flash-lights, amorphous zirconium, mixed with certain oxidizing agents, burns with a bright light; but it is doubtful whether the metal would be cheap enough to use in place of the usual material. Coherent white zirconium metal, on account of its acid-resisting properties, has been suggested as a substitute

for platinum; its alloys may be used in the manufacture of rust-resisting apparatus. Crucibles prepared from zirconium oxide have been proved superior for high-temperature work to any procurable on the market.

Zircon is found in considerable amounts in many placer deposits derived from disintegration of granitic and pegmatic rocks. The best-known deposits in the United States are near Green River, Henderson county, North Carolina, and in the Wichita mountains, near Cache, Oklahoma. Zircon is found most abundantly in certain syenites of Norway, and occurs in crystalline limestone at Grenville and elsewhere in Canada. Dana states that zircon occurs in various localities in North America, including Litchfield, Maryland; in Essex county, Orange county, and St. Lawrence county, New York; near Reading, Pennsylvania; abundantly in the gold sands of Burke, McDowell, Polk, Rutherford, Henderson, and other counties in North Carolina; with astrophyllite, in the Pikes Peak region in El Paso county, and at Cheyenne mountain, Colorado. In California and elsewhere it occurs in gold-bearing gravels. Baddeleyite (brazilite) is found in large deposits in Sao Paulo, Brazil. This mineral has also been identified in Ceylon, Sweden, Italy, and Montana. Samples of zircon sand from Pablo Beach, Florida, have been investigated, and recently as much as 3% of some of the auriferous sands of Idaho has been found to consist of zircon mixed with monazite. In Brazil, which is an important source of industrial ores, it is difficult, owing to the hardness of the ore, to drill holes for explosives; in handling large amounts resort is had to primitive methods. A large fire is built against an exposed face of the ore and kept burning for several hours, at the end of which time water is thrown upon the ore, which produces fracturing of the mass, permitting it to be sledged into pieces easily handled by one man. Most of the mines are distant from the railroad. Horses for other than saddle purposes are practically unknown, and the ore is transported to the railroad station by ox-carts carrying about one ton each. These carts are of the crudest character, having large, solid, wooden wheels, some 4 ft. in diameter and 6 inches in thickness. From 20 to 30 oxen are generally required for each cart, owing to the mountainous roads. The results of the investigations of the Bureau of Mines are available in Bulletin 186, 'Investigations of Zirconium with Especial Reference to the Metal and Oxide', by J. W. Marden and M. N. Rich.

Work in the Ivalo gold mines in Finland is to be put on a modern basis, according to a consular report. Steam-shovels and diggers have been ordered from the United States, with which it is intended to shift 500,000 cubic metres of soil per month. In connection with these, a special plant for washing gold will be established, so that nearly all such work will be done by machinery. The Ivalo mining district is between Kultala and Tolonen. Work is being carried on in the Ritakoski district. To facilitate transportation, the construction of 20 km. of road from Purnumukas to Ritakoski is being planned.

Book Reviews

The Editorial: A Study of Effectiveness in Writing. By Leon Nelson Flint. 262 pp. D. Appleton & Co., New York and London. Price, \$2.50.

The author is Professor of Journalism in the University of Kansas; the aim of the book is to elucidate "the purposes, possibilities, and methods" of editorial writing, with a view to assisting those who desire to do it well. The first chapter gives a sketch of the growth of this phase of journalism—"the flower of journalism", as the author says. In the United States the golden age of the editorial was the decade before the Civil War, when men like Greeley, Dana, Raymond, Medill, and Watterson indulged in a personal journalism that dominated public opinion. In latter days "the newspaper as a news-gathering and commercial institution has swallowed up the editor as an individual"; newspapers have ceased to be the personal organs of individual editors; "the voice of the great paper has become the voice of an institution". The greater influence of the news columns has led to the "frank mixing of opinion and news, and the more subtle handling of news for editorial effect". Mr. Flint regrets this development and says that "its advantages are bought at too high a price of loss in public confidence". This is a mild criticism. I would say that the tampering with news items is the unpardonable sin; it is to journalism what theft is to a banker, or lying to a clergyman. In the second chapter the weakness and strength of the editorial are analyzed. Sundry charges of weakness and futility are discussed. The one that appeals to me most is the assertion "that editorial columns are seldom used to acknowledge a mistake or to right a wrong". The correction or the withdrawal usually appears in small print in a corner of the paper. Justice demands, of course, that the apology or correction should be given at least as much prominence as the wrong statement. The failure of much editorial writing is imputed to the lack of a knowledge of technique. With this I agree. Few people dare to sing in public until they have learned the technique of singing; a good voice does not suffice, there is an art of vocal utterance that has to be mastered. Not many editors have troubled themselves to learn the technique of their art; it has grown like Topsy, without training or discipline. Some do fairly well if untutored, but even the best could do better if they studied the technique of writing, and the earlier in their career the better. There are right and wrong ways of doing things; the wise man endeavors to ascertain how something can be done in the only way that is worth while—the effective way. As Mr. Flint says: "Even the greatest editors might have been more powerful for a study of the technique of their craft". The editorial gives the newspaper a legitimate opportunity for exercising leadership. It is a mistake to suppose that editorials are not read. This may not apply to the prostituted newspapers of San Francisco, but in other cities, fortunate in the leadership of decent papers, it is true that men and women of the more intelligent kind read the editorials, "and a knowledge of their watchful eyes and alert minds is a constant inspiration to renewed care and labor" on the part of the editor. He is conscious—he must remain ever conscious—of those who "think his thoughts after him". This brings the author to his chapter on the editor and his readers. It is an excellent chapter. As I have said elsewhere, the first rule in writing is to remember the reader; to an editor it is necessary that he should have a knowledge of his following and keep them in mind when he is writing. "If his paper is a small one", says the author, "this is comparatively easy. He need only look up and down the street. If it is a metropolitan paper, he can learn much by personal observation and sometimes through the circulation department". If he does not, it is more than

likely that the circulation department will have something to say to him! It is not easy to read the public mind, but it is part of his fitness for his duties that the editor should have the ability to do so, and to do it the first requisite is sympathy. A wide human interest is a pre-requisite to the reading of public thought. If he possess this quality the editor "will early learn not to be misled by the clamor of those who take issue with him on some question. Those who approve are silent; those who disapprove are noisy. It is one of the unhappy features of editorial work that those who like what the editor says rarely tell him so. People have an unfortunate diffidence about expressing appreciation", and, he might have added, an inveterate hankering for dissent. That is not so unfortunate as it seems—apart from the self-esteem of the editor—because it brings to him the letters that are of the most interest to his readers. The average reader does not care to read compliments to the editor; he prefers the protest or objection that comes from the congregation, as it were, for he becomes tired of the pontifical 'we' and enjoys the tilt that calls the gentleman in the pulpit to account for his obiter dicta. Another factor will mitigate the editor's assertiveness, and it is one much less to be desired. The author refers to the selfish interests of the owners of the paper, which thereby come into conflict with the public interest. That, of course, is the milk in the coco-nut (not cocoa-nut). The plain fact stares us in the face that the cost of establishing or of acquiring a great newspaper in these days is so enormous that only the very richest men can afford to go into the business, and of those who have gained wealth the majority have done so by methods inconsistent with high ideals. This at least is certain, that the type of man fitted for editorship is rarely rich enough, or rarely able to make enough money, to acquire the control of the paper with which he is identified; the control rests usually with a politician, a speculator, or a syndicate of rich men. In his subsequent chapters Mr. Flint gives numerous excerpts from editorials, choosing his examples with notable catholicity of taste, and including sundry samples of second-rate stuff, for the purpose of illustration. 'Materials for Editorials' and 'Editorial Purposes' are two chapters in which he gives much useful advice to young men who are ambitious to succeed as editors. In the quotations that he gives to show the methods of some of our best-known papers I find plenty of errors, suggesting that even our best editors write carelessly, probably because they write hurriedly. Unfortunately not much of the editorial writing of the newspapers can claim to be literature, and the cause undoubtedly is the haste that is inseparable from such work. One remark made by the author I like particularly: "Without unduly emphasizing the value of observation, it may be said that the editor of the Chicago newspaper who refused to write an editorial against obstruction of the sidewalk by truck-handlers in the wholesale district until he had gone out and walked around a block or two of obstructions, so as to get a vivid, first-hand knowledge of the evil, was following the right principle". Again he is wise in laying stress on the point that knowledge is not all. Besides knowledge, sincerity of purpose, and technical skill as a writer, it is necessary for an editor to have the experience of life. It is "the determining factor in what the editor really amounts to as a man". He must have a philosophy of life, he must be social, he must be intensely human in his sympathy and outlook. No amount of knowledge fits a man to advise his fellows; the knowledge must be corrected and mellowed by the ups and downs of living, by the vicissitudes that help him to understand the feelings of others by 'going through the mill'. The intelligence tests of the Army failed in this respect; they ascertained that the average enlisted man had the mentality of a child of 13, but they ignored the fact that a man of 43, even if he have the mentality of 13, is greatly the superior of the child by

reason of his experience, which after all is a teacher that none should ignore. Again Mr. Flint refers to the readers as the editor's jury: "The editor who has not discovered his reader is in a position as absurd as that of an orator oblivious of his audience or a statesman indifferent to his constituents". In short, an editorial is not a soliloquy. But when Mr. Flint quotes Arthur Brisbane we are sickened, as when he quotes from the New York 'Evening Journal', to illustrate a vivid style. We feel strongly that a young man, anxious to become a good editor, should first of all recognize Brisbane, Hearst, and the others of the yellow fraternity as the pimps of journalism, as the exponents of all that is meretricious (from the Latin 'meretrix', harlot) in public writing, and that no amount of shallow smartness can condone the rank insincerity and the fundamental ignorance of such men. They represent the one influence that has debased, and is still debasing, American journalism. The omission to recognize this patent fact is the one blemish in a most useful book. I conclude by reproducing the author's quotation from George E. Vincent: "The press is more than a business. It is a social service fundamental to the national life, exerting profound influence upon it. The men of the press must recognize the social nature of their task. If the press be a corporation, it is a public-service corporation with all the responsibility that this implies." And I venture to add that without an honest and intelligent press it is impossible to develop or to maintain the sound public opinion upon which in the last resort depends the welfare of our democratic republic.—T. A. R.

Manual of the Oil and Gas Industry. Compiled by officials of the Treasury Department, U. S. Internal Revenue. 245 pp. For sale by the Superintendent of Documents, Government Printing Office, Washington, D. C. Price, 25 cents.

This manual as originally published in 1919 contained much information that was invaluable to the taxpayer in making out his return and supplying proper valuation data. Since the publication of the original manual, a number of Treasury rulings have been rendered; much additional information regarding the estimation of oil reserves has been collected, studied, and prepared for publication; also a large number of data have been collected and tabulated relating to the number of wells drilled, thus establishing a dry-hole hazard for various districts and fields. On account of the demand for this additional information, the revised manual has been issued to assist the taxpayer of the oil and gas industry to prepare his Federal tax returns correctly and expeditiously. Although endeavor has been made to anticipate all questions that may be asked regarding the law and regulations—and the latter have been amplified when it was deemed necessary to obtain the desired result—it is recognized that such a manual is only general, and cannot cover all information gathered by engineers, geologists, and other technologists, the object being to establish a basis for valuation depletion, and depreciation in connection with the oil and gas industry. Records of production of thousands of properties scattered throughout all fields in the United States were classified and studied by experienced engineers, with the result that average future production curves and tables are available for almost every producing district in the United States. The book consists of five parts. Part I deals directly with the law and regulations. These, as they relate to the oil and gas industry, have been prepared in accordance with recent Treasury decisions, and are explained by the inclusion of a number of illustrations and examples to bring out their application. Part II deals with the question of depreciation, and should assist the taxpayer in standardizing his classification of equipment. It also offers suggestions as to relative rates of depreciation for different types of physical property. The rates are not to be

applied indiscriminately to specific cases, but are relative only; the Treasury Department is in no way committed to accept them in the returns. Part III consists of descriptions and methods of estimating underground oil reserves, especially by means of production curves and tables. The material in this chapter was prepared by W. W. Cutler, U. S. Bureau of Mines, and Roger F. White, Bureau of Internal Revenue. A collection of curves and tables covering many of the pools, districts, and fields in the United States accompanies the text. The curves and tables are intended as a suggestion for the guidance of the taxpayer in the computation of his depletion allowance, which in turn has a direct bearing on the amount of his tax. They are not to be applied indiscriminately to specific properties, and the Treasury Department is in no way committed to accept estimates based upon them. Every claim for deduction on account of depletion must be accompanied by a detailed statement of cost, production, and any other data upon which such claim is based. Part IV contains tables showing, by States, counties, or districts, the number of wells drilled, revealing much information as to initial production, and the percentage of dry wells as compared with productive wells. This chapter was prepared by Albert H. Fay, Chief of the Natural Resources Subdivision, Bureau of Internal Revenue. Part V is a short chapter on the oil industry of Mexico; it contains notes on geology, production, and markets. This chapter was prepared by Oscar H. Reinhold. The investigations leading to the revision of the manual and its publication were made under the general supervision of C. F. Powell, former Chief of the Natural Resources Subdivision. The assembling and editing of the material submitted was done by Mr. Fay. Others who either contributed to, or reviewed the work were Norval White, Chief of the Oil and Gas Section, W. S. Clute, Percy L. Ports, and Burr McWhirt, all of the Oil and Gas Section, Bureau of Internal Revenue, and J. O. Lewis, former Chief Petroleum Technologist, Bureau of Mines.

Working of Steel. By F. H. Colvin and K. A. Juthe. 244 pp., 6 by 9, ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$3.

This treatise contains a practical discussion of the annealing, heat treatment, and hardening of carbon- and alloy-steel. Mr. Colvin is the editor of the 'American Machinist', and Mr. Juthe is the chief engineer for the American Metallurgical Corporation. As they state in the preface, the ever increasing uses of steel in all industries and the necessity of securing the best results with the material used, make a knowledge of the proper working of steel important. It is not the quality of the steel itself or of the alloys used in its composition, but the working or treatment of the steel that determines whether or not the best possible use has been made of it. With this in mind the authors have drawn, not only from their own experience, but from the best sources available, information as to the most approved kinds of steel now in commercial use. These include low-carbon, high-carbon, and alloy-steels of various kinds; the automotive industry has done much to develop new alloys and efficient methods for working them. The practice in Government arsenals on steels used in fire-arms is also given. Although not intended as a treatise on steel-making or metallurgy in any sense, it has seemed best to include information on the making of different steels, and to give a considerable amount of general information to those who desire to become familiar with the most modern methods of working steel. The contents of the book are as follows: I. Steel making. II. Composition and properties of steels. III. Alloys and their effects upon steel. IV. Application of Liberty-engine materials to the automotive industry. V. Forging of steel. VI. Annealing. VII. Case hardening. VIII. Heat treatment of steel. IX. Hardening carbon-steel for tools. X. High-speed steel. XI. Furnaces. XII. Pyrometry and pyrometers.

REVIEW OF MINING

JUDGE JOHNSON AWARDS UTAH-APEX COMPANY \$1,200,000

In his decision on the accounting of damages due Utah-Apex Mining Co. under the verdict awarded the company against the Utah Consolidated Mining Co. last year for illegal extraction of ore, Judge Johnson of U. S. Circuit Court at Salt Lake City finds that the Utah-Apex is entitled to \$1,200,000. The Utah Consolidated, in accordance with the original decision of the court, filed an accounting acknowledging that it should pay Utah-Apex some \$659,000. The latter appealed this and now the decision awards Utah-Apex \$1,200,000.

It is not improbable that Utah-Apex will enter another appeal, for, while this latest award is nearly double the amount of damages Utah Consolidated admitted in its accounting, it is not wholly satisfactory to the former company.

GREAT NORTHERN RAILROAD ISSUES NEW SCHEDULE OF FREIGHT-RATES ON ORES

The Great Northern railway has issued a tariff on ore between all points on its western lines and Bradley, Idaho, where the Bunker Hill smelter is situated. It will become effective on November 21, according to the statement of Frank M. Smith, smelter director for the Bunker Hill & Sullivan Mining & Concentrating Co. The tariff creates freight-rates where none existed. It will make the smelting services of the Bunker Hill available to producers in a wide area on the Great Northern lines. It will open the smelter to the gold, silver, and lead ores of Stevens county, the gold and silver ores of Okanogan county, the gold ore of Republic, all in Washington, and the gold, silver, and lead ores of British Columbia, as well as the silver and lead ores of Troy and Libby, in Montana. The minimum rate is based on ore having a value under \$30 per ton. An addition of 25c. per ton is made for each increase of \$10 in value up to and over \$100 per ton. The O.-W. R. & N. and the Oregon Short Line have established tariffs between points on their lines and the Bunker Hill smelter, but the Northern Pacific has issued no rate except from points in the Coeur d'Alene region and the smelter, according to Mr. Smith.

SECRETARY MELLON OF THE TREASURY DEPARTMENT SEES NO REASON FOR SUBSIDIZING GOLD PRODUCERS

Opposition to a subsidy of any kind to the producers of newly-mined gold was expressed by Secretary Mellon in a letter, dated October 13, to T. L. Oddie, Republican Senator from Nevada, in reply to a resolution signed by twenty-two Western Senators supporting the McFadden bill. The Treasury's position, Secretary Mellon said, had not been altered by developments since May, when he wrote the chairman of the House Ways and Means Committee, declaring the Treasury found no reason for such legislation. Mellon added that there are signs of improvement in general mining conditions, and he believed the abnormal effect of the War would gradually be eradicated without the aid of the gold-production subsidy. The Secretary called attention to the vast accumulation of gold in this country, saying that

the United States had the largest gold reserve in its history and the largest stock of monetary gold in the world. He denied that there was a shortage of gold and asserted that "there is nothing in the position of the gold reserve which makes it either necessary or advisable to encourage by subsidies or other artificial means new mine production of gold". Advocates of the measure contend that the proposed measure is not in effect a subsidy. On the contrary, they assert commercial users of gold for several years have enjoyed virtually a subsidy, since they have purchased gold from the Government much lower than the cost of producing it.

OPENINGS FOR METALLURGISTS IN BUREAU OF MINES

Two vacancies for associate metallurgists for the U. S. Bureau of Mines stations at Rolla, Missouri, and at Salt Lake City, Utah, and two for assistant metallurgists at Tucson, Arizona, and at Seattle, Washington, are to be filled by open competitive examinations given under the auspices of the U. S. Civil Service Commission. The salaries for the first position range from \$3000 to \$3800 per year, and for the second from \$2000 to \$2800 per year. Applicants for these examinations must qualify in at least one of the following optional subjects:

1. Physical metallurgy. 2. Electrometallurgy. 3. Hydrometallurgy. 4. Lead and zinc metallurgy. 5. Iron and steel metallurgy. 6. Copper metallurgy. 7. Some specialized line of metallurgy not included in any of the above.

Further information may be had by applying at the nearest office of the Civil Service Commission.

ARENTZ NOW OPPOSED TO THE MINING BILL THAT HE INTRODUCED

The following is quoted from the 'Reno Evening Gazette':

"In view of adverse criticism more or less general in mining circles of the State, a substantial share of which is directed unfortunately against S. S. Arentz, Congressman from Nevada, relative to the proposed new mining bill, letters received by friends here from Mr. Arentz within the week, cast timely light on his position in the premises. The language of one letter in particular indicates that Congressman Arentz availed himself of the opportunity to introduce the House resolution at the request of the chairman of the committee on mines and mining for the sole purpose of preventing from doing so some representative who might insist upon its passage and be successful in the operation.

"From the tenor of this correspondence, Congressman Arentz is unalterably opposed to the passage of the measure as it was drafted and he anticipates that it will be 'buried in committee', saying that it will not come before the regular session of Congress if he can prevent it. Congressman Arentz states that he agrees with the views of the prospector and the small mine operator with reference to the bill and it is apparent that the measure will not receive his sanction without radical revision.

"This illustrates pointedly how a representative in Congress must watch his political P's and Q's in the pursuit of his official duties if he expects to continue for long in his

capacity as such. It would seem, from his letter, that Mr. Arentz's purpose in introducing the bill was to keep it out of dangerous hands, his affirmative act in this respect seems to have been designed to accomplish a negative result. It is obvious that he desires to convey to the people of his home State that it is his intention to do what he can to smother the bill rather than to support it. Naturally, Mr. Arentz's political opponents will seize upon this occasion to injure him if they can, for they regard him as an assured candidate for the office of United States senator next year. And in this his friends and enemies are agreed."

COPPER SURPLUS, ON SEPTEMBER 1, ESTIMATED AT 950,000,000 LB., INCLUDING METAL 'IN PROCESS'

The total available supply of copper as of September 1 was 405,051 short tons, equivalent to more than 810,000,000 lb., according to a U. S. Geological Survey report. This did not include working stocks in transit and in process of refining. Estimating the latter around 140,000,000 lb., it would mean that total surplus stocks of crude and refined copper in this country at the beginning of last month approximated 950,000,000 lb. Copper producers say that this may seem a huge amount of metal to be overhanging the market, but they point out that fully half of it is what might be termed a normal surplus of crude and refined copper. They add that with a picking up in demand to anything like the equivalent of the world's actual needs, this surplus would not be a menace to a normal resumption of activity, but would disappear quickly.

Copper sales are running at the rate of approximately 100,000,000 lb. per month. Most of the big mines in this country are closed down, but production from those still in operation, including Miami, Kennecott, Chile, and Cerro de Pasco, coupled with the output from miscellaneous sources, has brought the output up to around 40,000,000 lb. per month.

This would leave around 60,000,000 lb. to be drawn from surplus each month, assuming that monthly sales keep around the 100,000,000-lb. mark, although the industry is sanguine that sales will show a big expansion through the rest of 1921 and most of 1922. At this rate, it would only take eight months to bring the surplus down under 500,000,000 lb., or a normal accumulation of crude and refined metal, including stocks in the hands of manufacturers.

OIL IN BRITISH COLUMBIA

C. O. Stillman, president, and a number of directors of the Imperial Oil Company, were in Victoria, B. C., recently, for the purpose of securing oil-concessions from the Provincial government, it is understood. Stillman stated that his company was disappointed, though not discouraged, at the results so far obtained in Alberta and the Northwest Territories. The company has drills in operation from the international boundary between Alberta and the United States to Fort Norman, and a great deal of money is being expended in exploratory work. The company will continue this work until some definite decision is reached. During the coming winter the company will extend its geological reconnaissance to the Pacific Coast, and if promising geological formations are discovered and satisfactory arrangements can be made boring operations are likely to be commenced in British Columbia next year. At the present time there are 50 men at Fort Norman, and work will be continued throughout the winter, although results have not been particularly encouraging up to date. It is not known what policy the Government will adopt with regard to granting oil-concessions. Two years ago the D'Arcy Development Co., a subsidiary of the Anglo-Persian Oil Co., applied for a concession in the Peace River region, giving it the sole right to explore over an area of 600 miles square, and at the end

of five years to select one-tenth of that area, paying the Government a royalty of 12c. per barrel at the casement-head, and undertaking, in the event of commercial discovery, to construct a pipe-line to the coast. The company undertook, too, to spend a considerable amount of money in exploration. This offer was refused, much to the disgust of many prominent mining men in the Province.

MILL TAILING NOT ASSESSABLE AS PERSONAL PROPERTY, ACCORDING TO FEDERAL COURT

According to decision handed down by Federal Judge Tillman D. Johnson, the collection of \$158,520 taxes by Salt Lake county from the Utah Copper Co. during the years 1917 and 1918 on tailing dumped near the Magna and Arthur plants at Garfield, was illegal. The county, in assessing the tailing, contended that after the ore was removed from the mine it ceased to be a part of the mining property and was assessable, the same as any other personal property. The Federal court holds that only the net proceeds from the sale or re-treatment of such tailing can be taxed. The complaint was filed by the copper company on April 2, 1919. The taxes amounted to \$79,894.50 in 1917 and \$78,625.50 in 1918. They were paid on November 30 of each year, under protest, and the company asks for interest at the rate of 8%, in addition to the principal.

AMERICAN MINING CONGRESS CONVENES AT CHICAGO ON OCTOBER 17

The annual convention and exposition of the American Mining Congress opened at Chicago on October 17. The principal object of the convention is to plan for a revival of the mining industry. As a means to this end the Congress is holding, in connection with its convention, a national exposition of mines and mining equipment, in which there will be 207 exhibits of mining machinery and displays of the resources in Mexico, Alaska, California, Utah, Colorado, and other mining States, including the Illinois and the anthracite coalfields and the Lake Superior iron-ore district.

Many of the country's leading business men will attend. Among them will be Charles M. Schwab of the Bethlehem Steel Co., who will speak on 'The Problems of Industry'; Charles Piez, president of the Link Belt Co.; E. M. Herr, president of the Westinghouse Electric & Manufacturing Co.; Edgar F. Smith, president of the American Chemical Society; Senator James A. Reed of Missouri; Governor J. A. O. Preus of Minnesota; Senator S. D. Nicholson of Colorado; Edwin Ludlow, president of the American Institute of Mining and Metallurgical Engineers; Francis S. Peabody of Chicago, who is chairman of the Illinois convention committee; Sidney J. Jennings of the United States Smelting & Refining Co.; Eugene Wolfe, president of the American Zinc Institute; Thomas D'Arcy Brophy of the Anaconda Copper Co.; C. H. Markham, president of the Illinois Central Railroad; George Otis Smith, director of the U. S. Geological Survey; F. C. Honnold, secretary of Illinois Central Operators' Association; C. H. Fulton, Dean of the Missouri School of Mines; H. Foster Bain, Director of the U. S. Bureau of Mines; Luis N. Rubalcaba, Assistant Secretary of Commerce and Industry of the Republic of Mexico. One of the sectional meetings of the convention is a national tax conference. Its object will be to work out means for securing a uniformity of mine-taxation laws in the various States. Another very important conference will be the second national standardization conference.

ALASKA

Anchorage.—The Willow Creek quartz-gold mining district, recently the subject of several news dispatches, some of them reporting sensational strikes, will become a "per-

manent deep mining camp during the coming season", in the opinion of A. H. Brooks, chief of the U. S. Geological Survey, who has just completed a preliminary examination of the locality. Seven stamp-mills have been built to crush high-grade ore. Development of the camp will mean a heavy tonnage for the Government railroad, mining men point out.

ARIZONA

Oatman.—The United Eastern company's No. 3 shaft is 750 ft. deep; a cross-cut will be driven at 800 ft. to the Red Cloud vein, which is proved on Tom Reed ground. The Big Jim shaft is to be developed to the 1000-ft. level; sinking has been started. The tram from the Big Jim to the United Eastern mill will be completed shortly.—The Oatman United company is diamond-drilling to prospect the vein which it now has on the 600-ft. level. The vein is small, but good assays are obtained.—The Alcyone Mining Co. has started diamond-drilling from the 400-ft. level to prospect its ground.

The Oatman Amalgamated company will resume work on

Harbor City.—The remodeling of the Kirk Simon smelter is nearing completion. The plant is controlled by the Simon Silver-Lead Co. of Mina, Nevada, and will be used to treat the zinc concentrate made at its new 150-ton mill. New flues have been built, and the furnaces have been remodeled to meet the latest requirements for zinc-oxide manufacture. Improvements also have been made in the bag-house department. M. P. Kirk, who originally built the smelter for the purpose of manufacturing material used in munition plants, is in charge of the reconstruction.

Melones.—According to W. J. Loring, president, more than 1,000,000 tons of ore is blocked-out in the mines of the Carson Hill Gold Mines Co. The average assay he estimates to be \$7 per ton. The 30-stamp mill is now operating at full capacity, the stamp-duty exceeding 18 tons per 24 hours.

Sonora.—A number of bonds have been recorded that involve mining property in this vicinity, the aggregate purchase prices being \$114,000. The options were obtained by J. E. King, who assigned them through a trustee to the

Map of Alaska

November 1 and will continue to cross-cut north to the vein; the shaft is 600 ft. deep.—The United American is sinking a winze on the vein to the 1000-ft. level.—Work has been started on the Henry Ford group on Silver creek. Several other small properties are preparing to work.

CALIFORNIA

Engelmine.—The Engels Copper Co. has driven its new working adit 800 ft. and is advancing at the rate of about 400 ft. per month. The distance to the orebody is 7600 ft., at which point the elevation of the adit will be 490 ft. below the present lowest level.

Forest.—The finding of rich gold ore on the 130-ft. level of the Kate Hardy mine is reported. About a month ago the new mill of the company was started and the new discovery is timely.

Grass Valley.—Rich gold-quartz ore has been found in the Normandle-Dulmine mine on Dead Man's Flat, according to T. C. Gwinn, superintendent. The vein is 2 ft. wide and was entered at the 150-ft. level. The company is financed by Mack Sennett and other motion-picture directors at Los Angeles.

Chilano Gold Mining & Milling Co. The properties are the Chilano, Santissima, Last Chance, Pine Tree, Carrington, Rice, Stockere, and J. A. Gillis claims.

COLORADO

Alma.—Lessees of the London M. & M. Co. have made a rich gold discovery on the Hard-to-Beat claim, situated about a mile from the main workings near the head of Mosquito gulch. The vein, 18 in. to 2 ft. wide, samples better than 52 oz. gold and 11 oz. silver. Sorted ore assays as much as \$1000 per ton. A car per day is shipped from the main workings, while the London tunnel, now in 2240 ft., is being advanced.—The Louisiana-Colorado Mining Co. has opened new orebodies in its adit; one vein, 2 ft. wide, assays as high as 750 oz. silver and 28% lead. This is on the Dolly Varden property.—Lessees are again operating the Excelsior, a former gold producer on Mt. Bross; the Criterion is also active and producing. These are adjoining properties.

Blackhawk.—The Silver Mt. Mining Co. has two cars of ore from the Black Jack and Wheeler Tunnel veins at the

Leadville smelter. The Black Jack ore is estimated at \$100 per ton and the Wheeler tunnel at \$65 per ton in gold and silver.

Breckenridge.—The Vulcan Syndicate has let a contract for 2000 ft. of drifting on the adit vein and another contract for the erection of three buildings at Chihuahua for the accommodation of miners.—The Penn mill is operating steadily and has both auto-trucks and teams hauling concentrate to the railroad for shipment to the Leadville smelter.

Central City.—The Polar Star mill is again in operation, treating ores from the Fairfield, Gold Rock, Ella, and Americus mines.

Cripple Creek.—Sinking has been resumed at the Portland company's No. 2 shaft, on Battle mountain. The shaft, now 2450 ft. deep, is to be sunk to 2650 ft. The station will be at an elevation of 7524 ft. and the shaft will then be the deepest in the State.

The Ajax mine now has 25 sets of lessees operating, and daily shipments go to the Independence mill of the Portland company; higher-grade ore goes to the Golden Cycle mill at Colorado Springs.—The Granite company has 12 sets of lessees active, in addition to operations on its own account.

The Mary McKinney Mining Co. has a diamond-drill exploring the main vein at depth. Should results warrant, the main shaft will be deepened.

Lake City.—Ore sampling \$37 silver and \$70 gold has been opened in the Golconda tunnel, 1000 ft. from the portal and 400 ft. from the surface. A cyanide mill is to be constructed for local treatment and a tramway built to the millsite. The property is in charge of B. C. Essig.

Monte Vista.—Mineral lands of the Baca grant, 12 miles long, extending along the western slope of the Sangre de Cristo range and nearly to the summit, have been secured under 10 years lease by James Allen, mining engineer of Monte Vista. The property will be developed at once.

Ouray.—The Atlas mine, 10 miles west of Ouray, and the mill are operating steadily. Ore from the Mountain Top mine, at an elevation of 12,000 ft., is being treated. The ore is high-grade, assaying \$200 per ton in gold and silver. The company has the largest payroll in Ouray county.

IDAHO

Coeur d'Alene.—The first 60-ton lot of concentrate produced in the mill of the Sunshine Mining Co. has been loaded at Shonts; it will be consigned to the Bunker Hill smelter at Bradley. In addition to the concentrate, the company has 30 tons of high-grade ore on the dump for shipment. The mill is receiving 40 tons of ore daily and producing three tons of concentrate. Jigs and vanners have been installed and the capacity will be increased to 75 tons per day. The hauling of ore from the mill to Shonts is done with a two-ton motor-truck, which makes the round-trip in an hour and a quarter.

Development is proceeding on the property of the Sterling Silver Mountain Mining Co. A vein was cut in an exploratory tunnel, driven 300 ft., but as work there would attain little depth it was stopped to concentrate effort on the main cross-cut, which is directed toward the second or main vein. Harry Morrel is manager.—Operations on the First National mine have been resumed.—The Blue Bell, between the Sterling and First National, is driving a short cross-cut from the lower level toward the vein.—The development of the Big Hill and Silver Dale, on the west fork of Big creek, is proceeding.

A question as to whether the Nabob Consolidated Mining Co. has two parallel bodies of ore near each other has been revived by the disclosure of a body of rich ore at the surface. The new body contains 4½ ft. of ore and has a lead

content of 20%. This lead content is contrasted with a 6% content in the highest stope of the Nabob, said to be within 50 to 100 ft. of the surface.

Mackay.—The Empire Copper Co. has been reorganized under the name of the Idaho Metals Co. The capitalization of the new company is \$1,200,000. It is expected that operations will be resumed at the property about November 1. For some time past, the company has been operating principally under the leasing system. L. R. Eccles is president of the new company; Ralph E. Bristol, vice-president; P. B. Porter, C. A. Boyd, and H. V. Jenkins, directors.

MICHIGAN

Houghton.—The report of the mine inspector for Houghton county, for the year ending September 30, shows a total of 3910 men employed in the mines, as compared with 6082

last year and 16,520 in 1916, a normal year. The Keweenaw county inspector's report shows a total of 883 employed in the mines of that county, the majority of them in Mohawk, with 549, and Seneca, with 137. At the Mohawk-Wolverine mill, 122 are on the payroll. The reports reveal the extent of the depression in the copper-mining industry in this district. The only operating mines are Copper Range, Quincey, Mohawk, and Wolverine; Seneca, Mayflower, and Arcadian, the last three being non-producers.

The mining companies of the district, which pay the bulk of the taxes, will benefit by a greatly reduced State tax the coming year. The amount to be raised in Houghton county for State purposes will be \$274,576, a decided drop from the present year, when the amount was \$383,868. The decrease is due to the fact that Houghton county's equalized valuation was reduced from its former total, while the figures for the State as a whole were increased.

Mayflower-Old Colony is still in material of commercial character in its main south drift from the cross-cut at the 1700-ft. level. For practically its entire distance of 300 ft. it is in good vein-matter, and it holds out the greatest promise of any opening in the property to date. No faulting is in evidence, and the belief is expressed that the best ore will continue to be found in this direction.

Owing to the continued high price of structural steel little construction work is under way in the district, most of the projects contemplated having been pigeon-holed until prices are reduced from present levels. The only important construction is the laying of water-mains from the Tamarack pump-station of the Calumet & Hecla to Ahmeek and from Calumet to the Ahmeek mill. This is more or less of an emergency relief project and is giving employment to between 200 and 300 men part time. About 20 miles of pipe is to be laid, which will supply Ahmeek, Allouez, Centennial, and Keweenaw with water as well as the settlement near the Ahmeek mill. The extension of the water-mains by Calumet & Hecla will permit the draining of wells and effect economies in pumping operations in the subsidiary mines.

The first city in the district to undertake organized relief work as a result of the unemployment situation is Hancock. An unemployment committee has been named and a day set for the registration of all residents of the city out of work. Funds for their relief will be largely raised by voluntary subscription. To help out, the Quincy Mining Co. is preparing to conduct logging operations on its lands near Hancock. Labor is plentiful for this work and the camps to be opened the coming winter will give employment to many idle men of the city and immediate vicinity. The timber will be used for mine purposes.

Calumet & Hecla has made two shipments, of 180,000 lb. each, by rail, to a customer in the Middle West. Both Copper Range and Quincy also have shipped considerable metal so far this month; it went forward by boat.

A total of 312 students have been enrolled at the Michigan College of Mines at Houghton, the largest enrollment in the history of the institution. Seven foreign countries are represented. Nine of the students are from China and one from Siam.

MISSOURI

Joplin.—The strength developed in the zinc market during recent weeks continues, registering a further advance of base prices to a range of \$23.50 to \$25. Even at the increased offering there was not a notable purchase of ores. The tonnage reported purchased at these figures was 5750 tons of blende or less than the week's output by a considerable tonnage. The strength in the spelter market has caused a marked hardening in the local zinc-ore market. Holders of zinc ore are firm in their demands for higher prices before selling the accumulations of ore in their bins. It will take a considerable advance in prices to secure any large amounts from the strongly held stocks, the tonnages available being from that portion of the regular output each week where the amount of lead ore is not large as a by-product. There is a tendency to increase outputting not only in the starting up of mills long idle but those already in operation are anxious to increase their production while the market shows some signs of going upward. Lead ore was sold generally at \$60 per ton for 80% lead, with reports of higher figures unverified.

MONTANA

Butte.—Butte & Superior Mining Co. is in a tax 'muddle' in consequence of the situation arising from the outcome of the recent litigation with the Clark Montana Realty or Elm Orlu Mining Co. Butte & Superior, in its tax return for the fiscal year ending June 30, 1920, listed as an allowable deduction under the Montana statutes, \$2,719,379, claiming this was for ores purchased from the Elm Orlu. This

amount, in fact, was the total of a judgment amounting to approximately \$217,000 for ores and for \$2,500,000, which was paid to the Elm Orlu interests in a compromise settlement of litigation then pending.

By including this sum as an allowable deduction the operations of Butte & Superior showed a deficit for the year and the County Board of Equalization appealed to the State Board and, to bring the matter to an issue, sought to claim a tax on the \$2,500,000 paid to the Clark people. The Clark people disputed this claim on the ground that the \$2,500,000 was not net proceeds on ore but was a payment for peace, being the compromise of the litigation. The Clark people set up that they could not be taxed on the ore in controversy as the suit was compromised, no decision being rendered as to its ownership. As Butte & Superior had been engaged in mining it and had claimed they were the owners of it during the litigation, the Elm Orlu interests could not be held as being the owner of this ore. The amount involved

Map of South-Western New Mexico

on which taxes are asked, so far as the Butte & Superior is concerned, is \$1,186,245 and of this amount 4½% is asked as tax payment, amounting to \$53,381.

Wise River.—According to John D. Pope, superintendent for the Boston & Montana Development Co., the machinery for the new 300-ton mill is in place and belts are connected ready for operation as soon as the Montana Power Co. completes the transmission line to the mill. At present the active work in the mine comprises drifting west on the Idanha vein on the 450 and 600-ft. levels. In this Idanha vein alone sufficient ore has been uncovered to keep the mill running at full capacity for many months. The company now has more than 300,000 tons of ore awaiting treatment. This ore will run from \$15 to \$20 per ton in copper, silver, gold, and lead.

NEVADA

Argentite.—F. H. Taylor, manager for the Natural Soda Products Co., which is developing under option the Frances group at Argentite, recently gave the first figures made public on the average length, width, and value of the ore.

Taylor said the 100-ft. shaft is sunk entirely in ore 3 ft. wide and of an average value of \$35. The 70-ft. tunnel near this shaft is in ore 6 ft. wide and assaying \$12 for the entire length. The 70-ft. tunnel 2500 ft. south of the shaft is entirely in ore 4 to 5 ft. wide and assaying \$25 to \$50. The Natural Soda Products Co. intends to build a mill if sufficient ore is developed. This company is employing 20 to 25 men, largely in road construction and in putting up buildings.

Ely.—During the period of shut-down 500 fifty-ton cars of ore averaging $8\frac{1}{2}\%$ copper and containing some gold has been shipped to the smelter and placed in the stock pile by the Nevada Consolidated Mining Co. The development of the high-grade orebody in the Ruth mine from which this ore comes is proceeding.

Hornsilver.—Constantly increasing interest is being shown in Hornsilver and it is expected that in the next two weeks a number of new companies will be organized. Except location work, practically nothing is being done yet outside of the Orlean. Tonopah and Goldfield men have been acquiring ground at reasonable prices for the last month, good claims being bought for \$500 to \$1500 each, but it is expected that prices will be boosted if ore is found on the 700-ft. level of the Orlean. Sinking of the Orlean shaft has been delayed because of repairs and it still is at the 680-ft. point, not yet in the vein.

The engineer probably most familiar with the district is Edwin S. Giles of Goldfield. He says that the district is promising because of the many places at which ore is exposed on the surface or in old workings. An instance of ore far from the Orlean is the Yellow Metal group, where two prospectors have opened an 18-in. width of \$52 ore containing 36.20 oz. silver and 0.80 oz. gold.

Las Vegas.—The Wet End Chemical Co., a subsidiary of West End Consolidated Mining Co. of Tonopah, has 50 men employed in the colemanite mine owned by the company in Clark county 18 miles from the Salt Lake railroad. The deposit is 50 miles from Las Vegas and the shipping point is 12 miles east of there, or 32 miles from the mine. A great deal of road building has been done and the grade has been reduced to a maximum of 7%. The ore will be shipped to the treatment plant at Searles Lake, in California. Colemanite is a hydrous borate of calcium. It is expected that shipments will be started about November 1. Hauling will be done by a 65-hp. tractor with four trailers, which will bring 25 tons daily to the shipping point. A 500-ft. tunnel has been driven at the mine.

Oreana.—The quarterly stockholders' letter just issued by the Pershing County Mines Co. states that the new boarding-house is nearly complete. Seven distinct lenses of silver-lead ore have been disclosed in the course of 200 ft. of drifting on the Jersey vein in property that was recently acquired. The vein will be explored to a depth of 400 ft. Work on the main Montezuma vein is said to be encouraging. Glenn D. Cook is manager.

Reno.—The Reno Chamber of Commerce is arousing the interest of Nevada mine operators in the conference between the carriers and shippers of ore that is to be held before the State public service commission at Carson on November 4. The conference has been called for the purpose of securing lower rates on shipments to Utah and California smelters and, as this involves interstate rates, over which the Nevada commission has no direct jurisdiction, the conference will be held merely in an effort to secure greater co-operation between the producers and the carriers.

The Reno Chamber of Commerce, at a recent meeting attended by 50 men interested in mining, supported a resolution unanimously condemning the proposed mining bill. Although some favored the repeal of the 'apex' provisions

of the present law, the general attitude was one of opposition to any changes, on the ground that they were neither necessary nor advisable. Bulkeley Wells, managing director of the Metals Exploration Co., passed through Reno and was quoted as expressing the opinion that if the law "were to be applied to new territory it might be good but applied to old conditions its good effect would be doubtful".

Winnemucca.—The shaft of the Harmony mine will be deepened to the 300-ft. point. The shaft has just been completed at 200 ft., where, according to George D. Williams, manager, a 5-ft. vein of milling ore containing copper, silver, and gold was exposed.

NEW MEXICO

Lordsburg.—The Calumet & Arizona Mining Co. has acquired the famous Norman King and Ballali group of mines in the Steeple Rock district. The properties, which were owned by H. W. Evans and L. C. Butler, were discovered more than 20 years ago. Development work was done on the Ballali group by the Carlisle Development Co. The Norman King mine was held until 1918, when it was opened up by John Christy, who shipped \$50,000 worth of ore. It has a 150-ft. shaft, but most of the workings are on the 100-ft. level. Messrs. Evans and Butler took over the property in May, and since then have developed considerable ore, and recently shipped a carload of high grade. A recent assay from a high-grade streak, six inches wide, in the south-east drift, showed 22 oz. gold and 1300 oz. silver per ton.

UTAH

Alta.—The initial shipment of ore from No. 3 raise at the Alta Tunnel property assayed 44.7 oz. silver and 23.3% lead, with small amounts of gold and copper. The ore netted the company \$57.15 per ton. In other mines of the district, notably the Emma, the highest-grade ore produced in by-gone days has been found in similar brecciated limestone formation.

American Fork.—Between 40 and 50 men are employed in the construction of the tramway for the Pittsburg mine, according to W. K. Yorston, manager. This mine is about 20 miles from the nearest railway point, and all materials and ore have to be transported by truck for that distance. About 144,000 ft. of cable and 8000 ft. of haulage-rope have been delivered at the mine.

Eureka. By October 1, the Water Lily shaft at the Chief Consolidated property had reached a depth of 1143 ft. During September the shaft was sunk a total of 406 ft. By November 1 it is expected that the water-level will be reached, and drifting will then be started.

Owing to the advance in the price of lead, local mines have been increasing production. During the week ending October 8, ore shipments totaled 178 cars, as compared with 144 cars for the preceding week. The Tintic Standard shipped 63 cars; Chief Consolidated, 40; Iron Blossom, 13; Victoria, 12; Eagle & Blue Bell, 11; Iron King, 9; Dragon, 8; Centennial-Eureka, 6; Bullion-Beck, 4; Colorado, 3; Swansea, 2; Gemini, 2; Mammoth, 1; Gold Chain, 1; Alaska, 1; Eureka Hill, 1; Sunbeam, 1.

Park City.—Local mining men are much pleased over the steady improvement in the lead market, and production is being increased as a result. During the week ending October 8, ore shipments totaled 1923 tons, as compared with 1805 tons the previous week. The Silver King Coalition shipped 765 tons; Judge allied companies, 720; Ontario, 393; New Quincy, 45. A shipment of 32½ tons made by the New Quincy Mining Co. from its recent strike gave returns of 55 oz. silver, 18% lead, 1.19% copper, and 42% insoluble, or a gross value of \$64.68 per ton. The ore continues to average as high as the initial shipment, and the indications are that the deposit is important.

BRITISH COLUMBIA

New Denver.—Clarence Cunningham has relinquished his option on the Van Roi mine, at Silverton. The Van Roi and the Le Roi No. 2, it is believed, are the only two remaining London-controlled mines out of the big group that was purchased in the early lode-mining boom-days. Cunningham obtained a bond of the Van Roi from its English owners in 1916 for \$225,000, and two years later a large sum was paid on the property, the owners agreeing to take the balance of the purchase price in royalties on ore-shipments, with certain provisions as to the minimum quantity of ore to be shipped. Under the option some \$350,000 worth of ore has been shipped, and, it is understood, the owning company has received about \$150,000. As the Le Roi No. 2 is said to be doing well since the erection of the flotation plant and as Trail is in the market, once again, for silver-lead ore, it is likely that the owner may operate the mine in future.

—Work at the Ivanhoe mill, which was taken over by the Silversmith Mines, Ltd., in the spring, and on the tramway connecting the Silversmith mine with the mill, is nearly

98% of this amount has come from the company's own mines. During the first six months of the year the company produced in the neighborhood of 24 million pounds of lead and 26 million pounds of zinc, compared with 26,474,652 lb. lead and 36,995,390 lb. zinc for the whole of last year. The company is said to have an immense stock of zinc on hand, but only about 14 million pounds of lead, or little more than four months supply under normal conditions. Now that the company is in the market for silver-lead ore, output is being curtailed at the Sullivan mine, and a number of men have been laid off. As the Sullivan ore runs about 12% of lead and 18% of zinc, the curtailment of output would seem to indicate that the company is desirous of maintaining its lead output and decreasing the spelter production. The splendid activity of the Consolidated during the depression in the metal market has done much to relieve what otherwise might have been a disastrous unemployment condition in the Kootenays.

ONTARIO

Cobalt.—The La Rose Consolidated is now producing

A Recent Photograph of the Plant of the Tintic Milling Company, at Eureka, Utah

completed, and the mill will be put into operation early in November.

Stewart.—Work is being pushed at the Silverton group, in the hope of getting things sufficiently far advanced before the heavy snow comes, and thus guarantee maintenance of operation through the winter. A good trail has been made to the 3000-ft. level, and work is being advanced on the tramway.—Dan and Andy Lindeborg are driving a tunnel in the lode at the Riverside group, which is only seven miles from here, and close to the Premier road. The Lindeborgs report that for 350 ft. the tunnel passed through ore that would average \$20 per ton, and that some of the ore would run over \$200 per ton. The ore contains silver and gold.—A cable has been received from the president of the Algonic Development Co., who is in Belgium, stating that arrangements have been made to settle up the back debts of the company, and that money was being forwarded for that purpose. The Algonic company did a large amount of development here last spring, at one time employing as many as 150 men. Final payments for labor were not made and some money was owing for haulage.

Trail.—All previous records have been beaten during the first nine months of the present year by the receipt of 307,493 tons of ore and concentrate at the smelter. Close to

from four mines which are yielding about 130 tons of ore daily. G. C. Bateman, general manager, states that production for the current year will exceed that of any previous year since 1917. The vein recently opened on the Violet is yielding some high-grade ore and a large tonnage of milling rock.—The report of the Bailey Silver Mines for September shows that the earnings of the Bailey mill were approximately \$13,389 from the treatment of 4466 tons of ore. There are good prospects for the re-opening of the McKinley-Darragh this fall. Upward of 25,000 tons of broken ore is in the mine ready for treatment.

Kirkland Lake.—In opening the 900-ft. level of the Kirkland Lake mine west of the main shaft, the drift, after passing through patchy ground for 150 ft. encountered ore yielding \$40 per ton. The mill is treating 135 tons daily with mill-heads of about \$9 per ton.

At the Wright-Hargreaves four levels are being developed from the main shaft. The mill is averaging 160 tons per day, the ore averaging \$15 per ton. The main shaft will be put down from the 400-ft. to the 800-ft. level with stations for levels at every 100 feet.

The Kirkland Lake Proprietary (1919) has decided to deepen the No. 3 shaft on the Burnside by 70 ft. and make it a central shaft for the operation of the Burnside and the

Tough-Oakes. Two of the Burnside veins have shown exceptionally well under recent development.

The heavy machinery of the Ontario-Kirkland mill has been installed and it is expected to be ready for operation in six weeks. Preparations are being made for a steady supply of ore. Stopes are being opened on the 300-ft. level. The mill will be able to treat 80 tons per day and it is expected that the recovery will average approximately \$15 per ton.

It is reported that Thomas W. Lawson, the Boston financier, will shortly visit the Kirkland Lake gold district to make an inspection of several properties for the purchase of which negotiations have for some time been in progress.

Porcupine.—The new orebody found on the 7th level of the Dome Mines Co., on ground supposed to be valueless, presents great irregularity of outline. It runs upward of 30 ft. in one direction, but otherwise its extent is undetermined. It is a slaty ore, very hard, with a high proportion of calcite, considerable quartz, and in places massive sulphides carrying as much silver as gold. Values average \$40 per ton. The orebodies opened on the 1150-ft. level have been proved by diamond-drilling to extend downward for over 200 ft. A raise is being made from the 1300-ft. level, on which development work will be pushed before further sinking. The mill is treating 1000 tons per day with mill-heads averaging \$7.50.

Operations have been resumed at the Davidson Consolidated. Lateral work is being carried on at the 600-ft. level and a contract has been let for diamond-drilling at a vertical depth of 1000 feet.

At the Triplex coarse gold began to show in the shaft at a depth of 90 ft. and at 100 ft. the gold content is stated to run \$500 per ton. The main dike of the Triplex property extends for 1½ miles and is half a mile wide with outcroppings which are stated to yield samples that assay \$35 per ton in gold.

Though continuous heavy rains have lessened the possibilities of a power shortage, the mining companies are taking no chances. The McIntyre has purchased a large amount of machinery for the installation of an auxiliary power-plant.

Skead Township.—An important ore-zone has been discovered on L. S. 30, one of the properties of the Skead Gold Mines. Eight parallel veins have been found within a width of 225 ft., seven of them showing an average width of 14 in. The eighth vein is 4 ft. wide and has been stripped for a length of 900 ft., and average gold contents as indicated by 66 assays are \$29.93 per ton. Eight hundred tons of this ore has been taken out.

South Lorrain.—A new vein has been opened in the lower workings of the Keeley. It is 8 in. wide and shows high-grade ore in the form of smaltite, carrying argentite and wire and leaf silver. The ore in sight is estimated at about a million ounces. Operations will be continued throughout the winter.

Sudbury.—C. V. Corless, general manager for the Mond Nickel company's Canadian operations, who has returned from England, where he was in consultation with the head officials, states that the mining and smelting operations of the company will not be further curtailed.

Swastika.—The Canadian Light Railway Construction Co., which will build a railroad from Swastika to the mining camps east and west of that point, has been reorganized with the following officials: president, C. E. Pinelle; vice-president, Dr. John Noble; managing director, Stephen A. Harnett; secretary-treasurer, H. J. Kirby. A contract has been let for clearing 160 miles of the right-of-way. The idea of building a narrow-gauge line has been abandoned and an application will be made to the Government for permission to lay standard-gauge tracks.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Laurence Pitblado is in Chile.

L. D. Ricketts is in New York.

R. M. Snyder has gone to southern Mexico.

L. C. Benny has moved from Fresno to Pasadena.

C. A. Richardson, of Cobalt, is on a visit to London.

H. R. Wagner is on his way from Berkeley to New York.

H. D. Bush has left Valdez, Alaska, and is now at Medford, Oregon.

H. B. Tooker, traffic manager for the Jackling companies, is in New York.

P. A. Robbins has moved from San Francisco to Highland Park, Illinois.

G. S. McKay has moved from Cusihuiriachic to Chinipas, Chihuahua, Mexico.

John V. Richards, of Portland, is at Long Beach, California, for the winter.

Morton Webber was recently at Cobalt, Canada, and has returned to New York.

D. W. Brunton motored from Denver to San Francisco; he is now on his way back.

H. R. Palmer, of Long Beach, California, has been examining mines near Prescott, Arizona.

A. E. Flynn has been appointed Professor of Mining in the Technical College of Nova Scotia, at Halifax.

W. H. Goodchild has undertaken a geological examination for the Kirkland Lake Proprietary company, in Ontario.

John A. Burgess is making a geological examination of the Rochester Silver Corporation's property at Rochester, Nevada.

Lionel Lindsay, formerly on the staff of the 'M. & S. P.', will be married in London on October 25 to Miss Yone Kennedy.

M. J. Cavalier, Professor of Metallurgy of the University of Toulouse, is now at Columbia University, as exchange professor.

Solon Spiro, president of the Silver King Consolidated Mining Co., has returned to Salt Lake City after a year's absence in New York.

Glenn Allen, mill superintendent for the Shattuck & Arizona company, has gone to Zacatecas, Mexico, to conduct some metallurgical experiments.

M. W. Hayward is the head of the newly-created geological and exploratory department of the Cia. Minera de Peñoles, a subsidiary of the American Metal Company.

Perry O. Harrison, heretofore consulting engineer to the Portland Gold Mining Co., has been appointed general manager for the company, succeeding George M. Taylor.

R. E. Palmer, consulting engineer to the Rio Tinto Company, spent a couple of days in Utah recently, visiting the Utah Copper mine. He is now in Montreal, and will sail shortly for London.

Jesse J. MacDonald, representing James Irving & Co., of Los Angeles, has just returned from a trip to the property of the Trinity Mines Co. in the Turkey Creek district of Yavapai county, Arizona.

Arthur L. Walker, Professor of Metallurgy in Columbia University, attended the Mining Congress meeting at Chicago on October 17, as representative of the Engineering Schools of Columbia University.

Henry H. Armstead has returned to Talache, Idaho, from New York to make an inspection of the construction work of the mill being built at Talache by the General Engineering Co. for the Armstead Mines, Inc.

EASTERN METAL MARKET

(By wire from New York)

October 17.—Copper is less active and softer. Lead is quiet and firm. Zinc is active and steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 floc) in British currency is 40.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

ELECTRIFICATION OF CHILEAN RAILWAYS

More than passing significance attaches to a contract with the Chilean State Railways in the electrification program involving equipment and other items amounting to approximately \$10,000,000. It indicates that despite general depression in most of the world, many countries are willing to do business, if on the right basis. Second, it shows that contrary to general belief, American firms can actually do business in face of foreign competition if the matter is approached intensively, says the 'Boston News Bureau'.

The \$7,000,000 contract for electrification closed by the Westinghouse Electric International Co. with the Chilean government, is the largest ever undertaken by an American firm outside the United States. The contract was awarded against European and American competition, because of lower price and engineering analysis. Additional contracts are being made with Chilean Railways for 20 freight locomotives from the American Locomotive Co., to cost \$1,500,000; 100 steel gondolas from the Pressed Steel Car Co., to cost about \$500,000. A contract with the Anaconda Copper Co. amounting to \$700,000 is included in the Westinghouse contract. Deliveries of materials and equipment are to start in two or three months, and the entire electrification project is to be completed in 24 months. Payments are to be made in United States gold in New York, and on practically a cash basis, as they are progressive as goods are delivered.

This is the first of four zones to be electrified; the second will be undertaken within five years, and will no doubt mean new contracts for the same firms, as developments in the first zone will determine standards for all. Equipment specified is patented and standardized.

Westinghouse was competing against the great German combination of Siemens & Schuckert together with Allgemeine Elektrische Gesellschaft. Hugo Stinnes is said to be heavily interested in the Siemens & Schuckert concern. Other Europeans competed, including the Swiss, while American competition included a combination of General Electric, W. R. Grace, and Foundation Co.

Westinghouse's bid totaled \$0,290,800 in United States gold, plus 2,334,196 pesos Chilean currency (\$466,800).

Westinghouse underbid the German combination by approximately \$4,000,000, at which the German bid was incomplete. In competition for the contract for steam locomotives, both Germans and Belgians were underbid by Americans. In July, when a contract for 41 locomotives was awarded by the Chinese railroads, Germans were underbid, five of the number going to American Locomotive and 36 to Belgium. Electric locomotives specified in the Chilean contract will cost about \$3,800,000. Baldwin Locomotive builds all but the power equipment for the electric locomotives.

Eastern Metal Market

New York, October 12.

A strong tone permeates all the markets, particularly copper and zinc.

Demand for copper continues with purchases each day aggregating substantial amounts.

Sales of Straits tin continue in moderate amounts at steady prices.

There is a fair demand for lead at firm prices.

The zinc market is strong with good demand at rising prices.

Antimony continues firm and steady.

IRON AND STEEL

The reduction of 28% in freight-rates on iron ore from both lower Lake ports and the seaboard, effective October 20, means little to the steel trade, says 'The Iron Age', except as it may point to lower freights on coal, coke, and possibly finished materials. While there has been much call from iron and steel producers for lower freights as a stimulant to business, fear is now expressed in the same quarters that buyers may be encouraged by the reduction on ore to wait for similar action on pig-iron and rolled steel and then to look for lower market prices. Producers contend that any saving on freights would merely act to reduce their losses.

The week's figures confirm recent reports of improvement, but to moderate degree. Steel-ingot production in September was 1,174,000 tons for the 30 companies reporting, against 1,138,000 tons in August, an apparent increase of 3%. But counting out Labor Day, the daily rate in September was nearly 10% greater than in August. The Steel Corporation's unfilled orders on September 30 showed the first increase (28,000 tons) in 13 months. But shipments in September on the large bookings of wire and sheets were less than the common estimate.

Japan's activity in rails is noteworthy. A late inquiry covers 5000 tons of heavy sections, following recent buying of 1500 tons of heavy rails and 3400 tons of light rails, the latter divided between British and German mills. In tin plate and sheets Japanese business continues to be a factor.

COPPER

The strength described as pervading the market last week continues and producers are taking every possible advantage of it by selling only a limited quantity at each slight advance in the price. Values have increased nearly each day until electrolytic copper for early delivery (30 days) is quoted at 13.12½c., delivered, or 12.87½c., New York. Some producers are not willing to accept business under 13.25c., delivered, or 13c., New York. Demand continues good with inquiries reported before the market as amounting to several million pounds in addition to the 10,000,000 lb. purchased by the American Brass Co. last week. There has also been a better demand for export with fairly large sales consummated to Germany at a price said to be 13.25c., delivered, Hamburg. On the whole the market is approaching a sellers' market instead of a buyers'.

TIN

Straits tin continues to be sold in moderate quantities each day, but there has been no large activity. Most of that sold was future shipment, largely November-December. Prices have been steady at around 27c., New York, for spot Straits, with futures about ¼ to ½c. higher. London prices were £155 15s. for spot standard on Tuesday, £158 5s. for future standard, and £156 5s. per ton for spot Straits. Arrivals thus far this month have been 1580 tons with 3445 tons reported afloat.

LEAD

There has been little change in the past week. A fairly steady demand continues at prevailing quotations, those of the leading producer being 4.70c., New York and St. Louis, with the outside market at 4.50c., St. Louis, and about 4.70 to 4.75c., New York. The market may be described as moderately active and strong at firm prices.

ZINC

Virtually the same conditions obtain in this market now that existed a week ago and these have resulted in higher prices, but the advance has been gradual. Producers continue to sell only their output and not their stocks. Output being under 20% of capacity, and demand having increased, the result is naturally a stiffer market. Prime Western for early or 30-day delivery is quoted at 4.60c., St. Louis, or 5.10c., New York, with some quoting 4.65c., St. Louis, as a minimum.

ANTIMONY

There has been no change in demand or values and the market is featureless and nominal at 5c., New York, duty paid.

ALUMINUM

The principal producer of virgin metal, 98 to 99% pure, continues to quote 24.50c. f.o.b. plant, for wholesale lots for early delivery, with the same grade obtainable from importers at 18 to 19c. per pound, New York, duty paid.

ORES

Tungsten: The market is reported weak because some sellers are anxious to dispose of holdings. Some reports are to the effect that most of the ore is in strong hands, who are 'hanging' on to it pending developments in tariff legislation. Quotations are nominal at \$3 per unit and higher, depending on the quantity and grade.

Ferro-tungsten: The market is lifeless and unchanged with the domestic alloy nominal at 40 to 45c. per pound of contained metal and the foreign at 50c. per pound of contained tungsten, duty paid.

Molybdenum: Quotations continue nominal in a lifeless market at 50c. per pound of MoS₃ in regular concentrates.

Manganese: Demand from any source is absent and quotations are nominal at 20c. per unit, seaboard.

Chrome: Quotations are nominal in a quiet market. Ore of 40 to 45% oxide of chromium in the cinder form are held at \$20 to \$25 per net ton, while higher-grade ore, 45 to 50% Cr₂O₃ is quoted at \$24 to \$26, both Atlantic ports.

Manganese-Iron Alloys: There is no change in prices, and demand is very light. British ferro-manganese is quoted at \$58.35 per ton, seaboard, and domestic producers are meeting this price in regular competition. Very little is heard of any demand for German ferro-manganese, which is quoted at about \$53, seaboard. Spiegeleisen is quoted at \$25 to \$26, furnace, and the market is quiet.

Coal-mine operators expect a boom about January 1, when large consumers stock up as a safeguard against possible difficulties arising from adjustment of a new wage-scale with the United Mine Workers, April 1. With open weather, new and old operations in the coalfields will be able adequately to fill these demands and little trouble is expected in transportation. Orders for shipments in the Connellsville, lower Connellsville, and West Virginia regions have been closed recently at prices as low as \$1.40 per ton f.o.b. mines, with almost any amount available spot, at \$1.50 per ton.

T. A. RICKARD, . . . Editor

W J. LORING has been re-elected unanimously to the presidency of the American Mining Congress, and his many friends will be delighted to hear of it. The Congress had a successful convention at Chicago.

ONE of the reasons why the price of copper has been so slow in recovering is suggested by the fact that the British government sold all its brass scrap recently to the British Metal Corporation. The purchase price was £4,000,000, which indicates the disposal of a considerable quantity of metal.

LENIN is a humanitarian, says Mr. Washington Vanderlip, in a public address delivered in San Francisco. He has "freed 150,000,000 white people from the toils of a monarchy" and therefore is to be compared, he says, to Abraham Lincoln. We venture to remark that a mining engineer who compares Lenin with Abraham Lincoln desecrates a noble memory and is a person so inaccurate that he might be expected to ignore the difference between a wild-cat and a bonanza, between a fraudulent scheme and an honest enterprise.

MENTION is made in a local newspaper of the fact that a well-known golfer was enabled to play successfully during a fog because, among other things, he rubbed his eye-glasses with a plug of tobacco, imitating a practice recognized among automobilists, who use the same method for keeping their wind-shields clear of moisture when it is raining. Here we have an example of the function of oily matter in lowering the surface-tension of water so as to prevent the wetting of a smooth surface. The oil from the tobacco is smeared over the glass and prevents the water from adhering to its surface.

ALASKA is recovering from the depression caused by the War. At that time the young men, the vigorous prospectors and miners, went into the Army, and the older men "turned their pockets inside out", as one of them phrased it. Moreover, the cost of supplies, always high in such a remote region, became prohibitive. Even at the beginning of the season this year—in May—many declined to buy supplies in preparation for a campaign of work because prices continued to be exorbitant; they preferred to wait until next spring, when we anticipate a

real revival. It used to be thought that only alluvial deposits existed in Alaska and the Yukon, but the development of the silver-lead veins of the Mayo and Kantishna districts and of gold veins in the Kuskokwim are so encouraging as to promise the establishment of lode-mining on a considerable scale. Alaska is one of the great mineral regions of the world, and the world will become alive to the fact again soon, as in the days of 1898 and 1899.

REVISED statistics issued by the Director of the Mint show that the production of gold in the United States during the calendar year 1920 amounted to 2,476,166 ounces, valued at \$51,186,900, which is a decrease of \$9,146,500 as compared with 1919, and \$1,677,500 more than the preliminary estimate issued in January. The record output was made in 1915, when this country produced \$101,035,700 worth of gold. In 1920 the production of silver was 55,361,573 ounces, valued at \$60,801,955; this compares with 56,682,445 ounces, valued at \$63,533,652 in 1919. In 1915 the output was 74,961,075 ounces, valued at \$37,397,300. The lower value of the larger output suggests how much the miner has benefited from the higher price of the metal.

ON another page of this issue we publish an article, by Mr. D. C. McGruer, on the treatment of the small quantities of impurities, chiefly copper, that exist in the ores purchased by the Sulphide Corporation, for treatment in their smelter at Cockle Creek, in New South Wales. Recently the Corporation decided to refine its own lead bullion, but the copper present in the ores was found to have a marked effect on the efficiency of the Parkes process. The method described in the article to which we refer was then introduced, whereby the objectionable element is removed, and, incidentally, a valuable by-product, bluestone, is produced that contains 99.23% of copper sulphate. This is marketed, and forms an additional source of revenue for the company.

CHARLES E. HUGHES, the Secretary of State, is reported as having made the following remark to a group of appointees to the consular service of the United States: "I confess that, in my experience with young men, the capacity I have found least often is the capacity for accuracy". He is not alone in his experience, unfortunately. In all branches of endeavor, other than in

the study of pure and disinterested science, there is a tendency to underrate the significance of a deviation from veracity, of the camouflaging of facts and figures, or of the cloaking of pertinent details. Such action is futile; it only reflects unfavorably on the doer; it is against common sense to evade the issue in such a manner, and no more important precept than this could be taught in schools, colleges, and universities. It was Thomas Henry Huxley who argued that science is organized common sense. The grandson of that great man, Mr. Julian Huxley, goes further with the definition: science, he says, is not content with the familiar, it is "organized curiosity". Here we see the connection between science and truth; for curiosity infers a desire to acquire facts—the why and the wherefore. Hence a study of science is the best foundation for an education that will be the forerunner of an attitude of impartial veracity throughout life.

DISCUSSION this week starts with a thoughtful letter from Mr. Russell H. Fraser, who writes concerning the prospects facing a recently graduated engineer, like himself. His letter will interest others who are on the threshold of a career, and it will awaken the sympathetic interest of those who can look backward rather than forward. We note that, by implication, he excludes the winning of oil from "the mining industry itself"; this is a common error; the search for oil and the recovery of it belong to mining just as much as the search for and the recovery of metals. The fact that a mineral is found in liquid form does not exclude it from the purpose of mining; sulphur is won in liquid form, sometimes salt and quicksilver; and even gold is mined from some alluvial deposits. However, that is a detail. We agree that the branch of mining devoted to the exploitation of oil-sand is attractive; it receives an assistance from geology that is even more direct than that given to the mining of the metals; it offers many interesting features in the ultimate operations of refining. Our contributor acknowledges that the young graduate in geology can hardly speak as an authority, but he avers that the training of such a graduate is "sufficient to solve many of the practical problems presented by mining". To this we demur, with a kindly smile. Experience underground and an apprenticeship of several years at the mines are needed before anybody is ready to "solve problems" that perplex those who have charge of mining operations. With Mr. Fraser's remarks concerning the many-sided character of oil-shale adventure, we agree; indeed his article is a commendable address by a new graduate, instead of the customary advice from a senior to his juniors; the latter will be more inclined to listen to views that come from one of themselves, for we have noted that young people think most of the advice that comes from a comrade just a little older, not a musty old 'has-been' whose outlook is backward. Another engineer, Mr. Paul R. Cook, discusses technical writing, chiefly for the purpose of protesting against the wordiness of some of the tech-

nical articles that he has been compelled to read. We second the plea for conciseness and simplicity; perhaps Mr. Cook will recall the fact that Herbert Spencer made a plea for economy of attention, arguing that the best style was that which involved the least trouble in interpreting the symbols of thought, and so left the reader with the maximum of attention for the thought itself. With the effort to separate the 'practical' from the 'literary' writer, we do not agree; the most practical writer is the one that succeeds best in communicating his ideas, and we have reason to believe that the so-called practical man is less likely to succeed than one who has studied the art of literary expression. However, we support Mr. Cook's motion condemning prolixity. An old friend, formerly in California, Mr. Douglas Waterman, writes from Havana on failures that are due to insufficient working capital; he makes some sensible observations and we hope they may elicit further views on the subject. Mr. Robert B. Brinsmade writes from Mexico on the subject of 'Non-American Issues', which we introduced in a recent editorial. He discusses proportional representation, as a means of circumventing the disproportionate influence of active minorities. Mr. William Motherwell, a metallurgist of wide experience, writes on the use of charcoal as a precipitant in cyanidation, and notes the use of this method at several mills in the Antipodes. Mr. R. van Aubel sends a note from Belgium asking for information concerning indicative plants. The best article on the subject is that by Rossiter W. Raymond in Volume XV of the Transactions of the American Institute of Mining Engineers.

IMPROPERLY ventilated mines are a menace to the health of the workers. An extensive study of the problem has been made by Mr. D. Harrington, of the U. S. Bureau of Mines, and an abstract of a lengthy paper by him appears elsewhere in this issue. In it the author deals with the factors of temperature, humidity, toxic character, and dustiness. It is mentioned that, in many cases, an atmosphere that is so foul that it will not sustain the combustion of a lighted candle is, from the viewpoint of a certain type of mine superintendent, entirely satisfactory. Emphasis is laid on the danger to health from the presence of dust. We learn that the average dust content of the atmosphere in five large mines in the United States was found to be 205 milligrammes per cubic metre. Mr. Harrington compares this with conditions in the Witwatersrand, where the air underground contains on the average, we are told, less than 5 milligrammes per cubic metre. Yes; it is well under 5 milligrammes; for the most recent report of the Standing Committee on Dust Sampling indicates that an analysis of 37,020 samples during 1920 showed an average dust content of exactly 2 milligrammes. Statistics indicate a gradual decrease in the dustiness of the big South African mines since the inception of definite scientific control of the problem. In 1915 the average was 4.9 milligrammes; in 1917 it was 3.8; in 1919, 2.4 milligrammes. It is unfair, however, to make comparison

with the average mine atmosphere in the United States without drawing attention to the fact that, in the Witwatersrand, the efficient control of such problems is simplified because of the contiguity of the properties and because there is a central body—the Transvaal Chamber of Mines—that fosters efficiency and economy by the appointment of working committees and experienced technical staffs; it constitutes a salutary influence in favor of reform in any direction; the recommendations of its special committees are enforced. The results of the systematic effort to allay dust in the mines of the Witwatersrand are chiefly of interest to American engineers as indicating that the misery and inefficiency caused by silicosis and phthisis are preventable.

The Railroad Strike

What may be the status of the railroad strike by the time these pages reach our readers we cannot foresee, but, whatever the event, the subject is one that calls for discussion on account of the principles involved. Such troubles can be obviated or overcome only by the creation of a healthy public opinion; for, in the last resort, it is public opinion that settles such matters under a democratic system. The immediate cause of this industrial crisis is the decision rendered by the U. S. Railroad Labor Board on June 1, which called for a reduction of 12½% in the wages of those working on the railroads. When the decision was made known it was referred to the members of the various unions of railroad employees and they voted in favor of a strike. The action of the leaders in calling a strike on October 30 is said to have been hastened by an intimation that a further reduction in wages was to be expected in due course. The question arises as to the jurisdiction of the Board that announced this reduction in wages. The Labor Board is acting under authority of an Act of Congress and is exercising powers delegated to it by the elected representatives of the people. The labor-unions are wrong in flouting an authority thus constituted; but, unfortunately, a bad example has been set by the other side. The directors of the Pennsylvania Railroad Company had defied the same Board previously, declaring that its action in ordering the election of representatives of employees for the purpose of negotiating with the officials of the company was unlawful. The railroad company refused to deal with anybody not on its own payroll, just as if corporations were not in the habit of engaging lawyers, and others, to represent them in large controversies. For example, Judge Gary is essentially the publicity man of the Steel Corporation; from the point of view of organized labor he is a Lewis or a Stone. In these matters one must be fair. It is curious how little has been said in the daily press about the refusal of organized capital to comply with the ruling of the Labor Board, and how much has been said about the similar refusal on the part of organized labor. Both are in the wrong. The public, however, considers rightly that the

action of the labor leaders in threatening a general strike is the worse offence, because it is the more serious in its immediate effects. Any organization within the structure of society as a whole is tolerable only so long as it does not interfere with the public welfare. The threat to cripple the entire system of railroad transportation, in order that a small minority may prevail in an industrial controversy, is an act of sabotage; it is an anti-social act that breaks the fundamental code of civilized life. Under our system no one, not even the Government, can compel a man to work, nor can any man be prevented from ceasing to work. Moreover, we have no satisfactory means for compelling the parties in an industrial quarrel to submit their differences to arbitration, and there exists a strong disinclination to enact laws for this purpose. The experiment has been tried, with questionable success, in Canada and Australia. Even if arbitration were enforceable, there remains the need for enforcing the decision of the arbitrator. The use of military power by the Government for this purpose is repugnant to our people; the average citizen rejects the thought of allowing such coercion. Already the cry of "less government in business, and more business in government" has been raised, and echoed freely. What apparently is needed at this juncture is a benevolent despot, who would cut the Gordian knot promptly and tell both the railroad companies and their employees to behave themselves, and not add to the many troubles from which we are now suffering in consequence of a hideous war. A despot may be useful for a moment, but, to our democratic way of thinking, he is detestable during the remainder of the time; so we shall do the best we can under the deficiencies inseparable from a liberal form of government. As a people we prefer an excess of liberty to a chance of tyranny, and all our constitutional safeguards are framed to this end. Here it is pertinent to recall that our democratic system was insulted in 1916 when the Adamson Act was passed under threat from the so-called Big Four, the leaders of the principal railroad-labor unions. The bulldozing of the Senate by these representatives of labor is responsible for much of the present trouble, for it established a shameful precedent and at the same time fixed working conditions that rendered impracticable the profitable operation of the railroads. As to whether wages are too high or too low, it is difficult to say, because the statistical data offered by the two sides are contradictory; the Labor Board ought to furnish impartial information on this point without delay. In a general way the public understands that the wages of railroad employees were raised during the War and that they ought to be reduced now, in common with other forms of labor and in accord with the decrease in the cost of living. A refusal to discuss the matter of wages or to accept the decision of competent authority, by using the threat of a general strike, leads only to disorder. The railroad companies and the labor-unions alike have been summoned before the Labor Board; the public will insist rightly that both

shall abide by the rulings of an authority established by Congress. The strike is in defiance of the Government and therefore deserves public reprobation, as does the flouting of the Labor Board by the Pennsylvania Railroad Company. The leaders on both sides could be indicted for conspiracy if the charge could be established; but this would prove difficult. Without clear proof of conspiracy nothing can be done to interfere with the legal right of the citizen to quit work. Meanwhile, there is one thing a government can do, and the Government must do, and that is to restrain the parties to the strike from acts of violence or any other interference with the liberty of the citizen and the safety of his property. If the strike must come, and if no better method be available for settling the controversy than this form of industrial duel, then both parties must be held to strict account. The public is keenly irritated by the crass selfishness of the railroads and the unions, and is in no mood to endure any further infraction of the law, especially if it take the form of gun-play. The public is the jury, and in the end its verdict will prevail.

America's Rubber Supply

The race for rubber has ended in the collapse of the participants. The synthetic substitute has been out of the running for some time; in quality and cost of production it failed to meet requirements in Germany during the War. Plantation Para rubber is quoted at under 20 cents per pound; the guayule substitute, previously imported from Mexico, is unprocurable, and its manufacture is little likely to be revived. Rubber is an essential in mining and allied industrial engineering work. Because it can be bought cheaply at the present time is no indication that the subject is undeserving of consideration. History has shown that the cost or the availability of certain essentials in time of peace and in time of war, respectively, are two very different matters. Prior to about 1900, almost the whole of the world's supply of Para rubber, for that is the standard, came from Brazil; but at the beginning of the present century the industry was tottering for a fall. The Monroe Doctrine discountenanced European interest in South America, but it did not prevent the transference of a South American industry to the Eastern tropics; and so it was that in 1876 a load of rubber seeds was cleverly exported from Brazil under the very noses of the authorities; from this beginning have sprung the great rubber plantations in the Orient. Brazil adopted the usual Latin-American tactics, which invariably serve to kill local initiative and industry. Tax after tax was elapped on the rubber leaving the country; in the decade between 1907 and 1917 the exports fell from 68,000 to 53,000 tons. The trees were ruined, and no attempt was made to encourage scientific cultivation. The money obtained from the export-tax was diverted from the industry and was wasted in governmental extravagances. The end was inevitable. In the meantime, with intensive cultivation and scientific control, the output of the transplanted rubber trees,

during the same period, rose from about 1000 tons to over 200,000 tons per year. A predominating proportion of this output is now grown in British plantations and in British territory. The United States uses about 80% of the world's supply, and produces almost none. At the present time the supply exceeds the demand. Prices are ridiculously low, and further expansion is improbable as a result of the investment of American capital abroad unless an incentive be offered.

Substitutes came into prominence about 20 years ago, when rubber was selling at a high price. The Germans were ahead in initiative of this kind, for they realized that war might mean isolation from the source of supply; and so it was that intensive research on their part, and also on the part of the British, led to the substitution of a rubber that was made from various materials, including potatoes. However, as with synthetic nitrate, the manufacture of which was also an apparent success, the artificial rubber that was made failed to qualify as an efficient substitute for the natural material, even disregarding the high cost of manufacture. Rubber is a substance that is needed extensively in modern warfare; the insufficiency of a dependable product was felt keenly by the Central Powers in the recent conflict. Great Britain, on the other hand, was able to draw on the supplies from the Eastern tropics for her needs as well as for those of the United States and the other Allies. As with nitrate, the United States had to depend on the good offices of Great Britain for a supply of rubber; there was no shortage, and prices were maintained at a reasonable level. Steps were taken in America to exploit the extraction of guayule, which is obtainable from a shrub that grows in northern Mexico, the cultivation of which had been attempted in Arizona. Although far inferior to Para rubber, this substance found a sale in the United States. It finally ceased to compete against Para rubber, the industry having been discouraged by the export-taxes with which our Latin-American friends obtain so much of their revenue, and was killed finally because of competition with the superior product of the Eastern plantations. The yield of latex from the guayule shrubs under cultivation in the United States is so small that there is little likelihood of the venture becoming a financial success. The present situation with regard to rubber may be epitomized in a few words: the artificial cultivation of the Brazilian rubber tree in the Eastern tropics, away from the tiresome restrictions and export-taxes that discourage industry in so many Latin-American countries, has been amazingly successful; an exceptionally high-grade and clean material is produced at a low cost; the United States uses about 80% of the rubber that is grown throughout the world, and controls only a small proportion of the supply; although the synthesis is of scientific interest, the commercial production of a substitute for Para rubber is as likely as the manufacture of artificial carrots.

The British are often designated a nation of shopkeepers, but it must be admitted that they are willing to do pioneer work in the outposts of the world. Today we

are dependent on foreign nations for a supply of two essentials in peace or war—nitrate and rubber. In peacetime such an arrangement is not undesirable, for economic existence involves buying as well as selling; but complications arise in war-time, and friction develops, as it did between the United States and Great Britain during the Great War. As Dr. Edwin E. Slosson mentions in 'Creative Chemistry', much anxiety was caused in this country during the early period of the War when Great Britain suspected, with justification, that American rubber goods were going to Germany by way of 'neutral' countries. In consequence, Great Britain abruptly shut off our supplies, as she was entitled to do. "This", Dr. Slosson adds, "threatened to kill the fourth largest of our industries, and it was only by the submission of American rubber dealers to the closest supervision and restriction by the British authorities that they were allowed to continue their business. Sir Francis Hopwood, in laying down these regulations, gave emphatic warning that 'in case any manufacturer, importer or dealer came under suspicion, his permits should be immediately revoked. Reinstatement will be slow and difficult. The British Government will cancel first and investigate afterward'." Uncle Sam may say that no nation can be aggressive without ample financial backing, and that there can be no more war if the United States will not lend. But other nations also hold trump cards: Chile controls the supply of natural nitrate; Great Britain, the supply of rubber; these commodities cannot be smuggled into the country in sufficient quantities in a few trunks, in the same way that the platinum shortage was relieved during the War. The United States may own a large proportion of all the real money in the world; but a million dollars in gold is of little use to a man who is in the centre of a desert and who wants a drink. What then of the future? Our satisfaction in being able to obtain cheap rubber from British plantations may be short-lived, for the formation of a Rubber Growers Association is being mooted in London, by which the output would be restricted and the price would be controlled in regard to at least two thirds of the rubber-planted areas of the world. Thus it may be that the period of cheap rubber is likely to come to an abrupt conclusion. As with Chilean nitrate since the Armistice, we may have to go without or pay 'through the nose'. The answer to the nitrate problem is expansion at home; we have the resources and the ability. The answer to the rubber problem is expansion abroad; we have the land in the Philippines, although we seem to lack a colonial policy. It takes from five to six years to bring a rubber plantation into bearing, so that the sooner the work is commenced the better. It is stupid to delay because of the present low price of rubber. Plantation rubber has been proved to be a commercial as well as a technical success; there is no hope for a synthetic substitute. Already we have had many bitter experiences in the initiation of industries in Latin-American countries; the Philippines can provide us with a steady supply of a national necessary; thus can we be free from dependence on foreign

nations in time of emergency, and from the price-fixing tactics of foreign trusts in time of peace.

Precipitating Copper With Iron

Just now there is a healthy interchange of ideas between exponents of the various branches of metallurgy; it is found that many an excellent piece of apparatus is also applicable, in a modified form perhaps, to perform an alternative task and to work under entirely different operating conditions. The rapid rise of the cyanide process during the earlier years of the present century resulted in the development of much ingenuity in the design of apparatus to meet the varying conditions that prevailed; the problem of treating the refractory slime that so often resulted from the pulverizing of a gold ore claimed much labor and thought. Various devices of intermittent operation were evolved to ensure the isolation of dewatered slime from a pulp of normal fluidity, but the majority were unsatisfactory; continuous personal attention was needed, and chokage was common. Further, an insistent demand arose for a continuous process throughout. Thus it was that, in 1906, Mr. J. V. N. Dorr invented a machine, now so well known throughout the metallurgical world, for the automatic removal of thickened sludge from ore-pulp. This apparatus, since modified and improved to a point that ensures satisfactory service and an almost complete freedom from breakdowns, has found wide application in gold and silver metallurgical plants; it has also been adopted extensively to dewater concentrate, and to prepare, for treatment in filters or driers, various forms of finely divided material in a fluid pulp. In a recent issue Mr. Joseph Irving, Jr., described a novel application of the principle on which the Dorr thickener operates, to that branch of copper metallurgy in which the metal in solution is recovered by scrap-iron. The usual method of treatment is inefficient; the improvement effected by the substitution of the Dorr-Irving system is marked. Not only is the work simplified, but the extraction is higher, and operating costs are lower. An additional advantage, which was not mentioned in the article in question, is seen in the fact that the Dorr vat will take precipitant in almost any shape or dimension; a discarded boiler will serve as readily as will a ton of tin-cans. Consequently, much scrap of large dimension will be available for the purpose and without the added expense of breakage to a size that is necessary in the case of precipitation in launders. More recently, Mr. Irving and his father have been engaged in the development of a heap-leaching process for the treatment of low-grade and mixed copper ores; promising results are being obtained. The copper metallurgists have borrowed and adapted ideas that were developed during the early days of the cyanide process, now seen in the leaching of comparatively coarsely crushed, mixed, dry ore, and in the use of such apparatus as the modern automatic thickener, the mechanical classifier, and the vacuum-filter. However, the time may not be far distant when the tables will be turned, and the cyanide metal-

lurgists will be glad to borrow back the original ideas, plus the added improvements that have been made in the preparation of the ore and in the development of large-scale methods, all of which will be of considerable value in connection with the treatment of material from low-grade precious-metal deposits. To the mining engineer, and more particularly to the metallurgist, there is nothing that is ingenious or efficient from the mechanical point of view that is not worthy of attention. Much progress may result from the adaptation of ideas from other industries and as a result of the interchange of ideas between the various departments of our own industry.

Hygiene in the Tropics

Good engineering coupled with faulty hygiene means ultimate disaster in the tropics, as the French found when they attempted to dig a canal across the Isthmus of Panama; many failures in mining can be attributed to the same cause; no enterprise can justify its existence in such places unless adequate provision can be made against the incidence of tropical disease. The work of the health department of the Panama Canal has been persistent since the commencement of operations. Vast expenditures have been made, but the outlay has been repaid in the saving of life and in the general improvement of conditions on the Zone. The annual report, for 1920, is to hand; in it Colonel H. C. Fisher, the chief health officer, gives much interesting and educative information. That prevention is better than cure is an axiom of the first importance with those in control of the health of the residents in tropical settlements. The work of draining swamps in the vicinity of the canal goes on unabated, so that the number and extent of breeding places for mosquitoes have been reduced to insignificant proportions. This, together with the capture of the *anophiles*—as an anti-malarial measure and as an index of distribution—has reduced considerably the prevalence of the disease. It is interesting to note that the open ditch, lined with concrete, has proved unsatisfactory for drainage purposes in the jungle. Many deciduous trees are constantly casting their foliage; the drains become blocked; this leads to the formation of many small collections of still water. Although more easily swept and maintained clean than the earthen ditches, the constant care necessary to prevent mosquitoes from breeding after times of slight rainfall involves danger and expense. Most of the ditches of this type, of which there is about 10,000 feet in the Ancon-Corozal district, are being closed; broken rock and sectional covers are being used for this purpose. Future construction will be with 6- or 8-inch concrete tile, made locally, and covered with broken stone.

The use of quinine as a prophylactic, to prevent malaria, is by no means an ideal method, Colonel Fisher admits, nevertheless, the drug has been instrumental in causing a marked reduction in the number of cases among those from neighboring cattle-camps and planta-

tions. There are better ways of controlling malaria; but the isolation of these camps, their temporary nature, and the fact that the labor is recruited from the infected native population renders advisable the use of quinine. Every day during the first two months of employment each man is given $2\frac{1}{2}$ ounces of an alcoholic solution that contains 10 grains of the sulphate; after the first two months the same dose is prescribed for the morning and evening of each Wednesday, so long as he remains in the camp. This treatment is not compulsory; but it is interesting to note that the incidence to malaria has been lowest in those settlements in which the prescribed measures have been followed closely. For the sterilization of malaria 'carriers', and for the 'follow-up' treatment of ordinary cases, the administration of 10 grains of sulphate of quinine, every evening before retiring and for a period of eight weeks, has been adopted as standard. Results speak well for the efficiency of the medicinal and preventive work of the health department; for instance, the death rate from malarial fever among employees and non-employees in the Canal Zone and among the people of the cities of Panama and Colon, over which it exercises jurisdiction in health matters, has shown a consistent and steady decline. During 1906 it was 9.49 per 1000; during 1920 it was 0.08 per 1000. The recognition of the primary importance of health conservation has been an important factor in the successful engineering work that is associated with the American enterprise on the Isthmus. Those who have an opportunity to study the progress being made in preventive medicine and hygiene there should do so; the health administration in the Canal Zone is doing work of which this country may well be proud.

While on the subject of prophylaxis it is interesting to note that the 'Chamber of Commerce Journal' states that investigations are being made in connection with the medicinal properties of a forest tree that is indigenous to India. One of the civil surgeons of a district in Bengal, having noticed the number of cases of malignant malarial fever, made enquiries among the natives to find whether they used any local plant as a cure. His inquisitiveness was fruitful of result, which recalls the circumstances under which quinine became known, for it appears that there is a tree (*Vitex peduncularis*), found in Chota Nagpur, in Eastern Bengal, and in the Khasia Terai, that contains an unknown drug which may prove to be a valuable addition to the stock of prophylactics for use in the tropics. After adequate treatment of persons suffering from malaria it has been demonstrated, by microscopical examination, that the parasites had disappeared from the blood. The new remedy is said to have several advantages over quinine. It has no bitter taste; it functions as a stimulant, and so may be used by those in delicate health. For mining engineers whose professional work takes them to malarial districts, and who have an unpleasant recollection of the after-effects of the administration of sufficient quinine to avoid or to cure an attack of malaria, the new drug may prove of considerable value.

DISCUSSION

The Question Confronting the Graduate

The Editor:

Sir—It is natural for one about to enter a new field of activity to seek information regarding it which will enable him to anticipate some of the problems and more pertinent questions that may arise in the course of things. Thus the man about to graduate from college and take up his profession is wont to ask innumerable questions and seek the opinion of those experienced in the particular work he has chosen as to what the future may hold for him. The technical graduate is no exception. Like others who, having completed their college work, are looking over the situation before setting their course, he finds himself at the headwaters of many streams of industrial activity, and wisely hesitates before choosing one or another into which to launch his future. I shall consider the position of the graduate in mining engineering.

Perhaps no broader field is open to any technical graduate than that offered by mining and its allied industries to the untried Engineer of Mines. His college work has prepared him to make a beginning in practically any branch of the industry. If during his college career he has followed a course pertaining to a particular branch of the industry, he may further use his judgment in choosing one or another phase of that branch upon which to concentrate his efforts. It is said that this is the day of specialists. It is undeniable that the opportunities for young men in specialized fields today are far more numerous and attractive than they have been heretofore. The intensity of our industrial development has brought this about. But it is nevertheless true that a broad knowledge of a field is essential to intelligent and successful specialization in it. Herein lies the fallacy of specializing too early. Then too it is unwise for the embryonic engineer to place all his eggs in one basket, for some unforeseen economic force may temporarily remove the demand for his services, leaving him in a state of coma.

Consider the diversity of subjects to which the Engineer of Mines can apply himself: The man who has majored in mining geology has a choice of several fields in which to work. As a member of the geological staff of an oil company he may direct his energies to the determination of oilbearing structures and oilfield development—thus finding a stepping-stone into the petroleum industry; or he may array himself against the geological problems met with in metal mining, coal mining, and quarrying. In recent years, with the feverish search for

new oilfields, the man who at college has followed oil-geology has found his services in great demand. The attractiveness of this field has won many undergraduates to the cause of economic geology. With the acceptance of the anticline theory and its practical demonstration, the well-oil industry has developed, in great measure, in proportion to the proving of certain folded areas in oil-bearing strata. However, the ever-growing demand for petroleum, and the fact that a large number of wells have been 'brought in' in areas to which the anticline theory does not apply, urge us to seek an additional hypothesis to that afforded by the anticline theory through which to attack the problem of maximum exploitation of oilbearing strata. Here is a problem for the geologist. His position in the oil industry may rapidly develop into that of production engineer, where the question of maximum recovery replaces that of favorable structure location. The problem of increasing recovery from known oil-pools remains to be solved satisfactorily. Present operating methods recover an average of but 20% of the petroleum content of oilbearing strata. Some of the more successful methods of increasing recovery involve the application of pressure to the oil-sand by means of compressed air or water, pumping, and the removal of wax accretions from the casing by means of live steam or radiation from hot pipes. Various solvents have been used with indifferent success in attempting to re-establish flow in sands clogged with heavy hydrocarbons. The most heroic of these processes, however, has not approached the ideal recovery.

In the rôle of production engineer the geologist will find himself studying the various methods of drilling, the good and bad features of different types of drilling machinery, the applicability of wet and dry drilling to the problem in hand, the human element in his work, the philosophy of the driller's crew, and the economic factors of the work. Although his original duties were of a geological nature, he may eventually find himself installing a pipe-line or erecting a tank-farm, as his apprenticeship in the industry progresses. His work may even remove him from the field to the refinery, with its multitudinous temperatures and cracking processes. The petroleum situation in the United States has reached a point where it is necessary for us to seek additional resources in foreign territory in order to meet the demand for oil at home. At present approximately 20% of the petroleum consumed in the United States is imported from Mexico. American interests in foreign countries require American representation, and the prospects for

young engineers in such organizations are very favorable. The objection may be raised that an engineer engaged in foreign service will be completely out of touch with the industrial conditions at home upon his return. That may be true in many cases, but fortunately perspicacity is not absent from the mental equipment of engineers as a class.

The mining industry itself offers a fertile field to the young geologist. Placer operations may demand his guidance. The successful development of a metal mine may depend upon his judgment. Today, when the mining industry finds itself practically bereft of the old-time prospector, the engineering geologist must take up the task of finding new deposits of valuable minerals. Scientific prospecting is replacing the Forty-niner's methods, and though the new regime will undoubtedly produce greater results, it is doubtful whether the work can be done any more conscientiously. The necessity and the opportunity for research in geological subjects is considerable. True, the graduate in mining geology is far from being an authority on the subject, yet his knowledge is sufficient to solve many of the practical problems presented by mining and its kindred industries. For the solution of the more intricate theoretical problems of geology post-graduate work is a prerequisite to intelligent research.

Although the mining engineer, acting in that capacity, need not be an expert metallurgist, yet the minimum of metallurgical information required of the engineer, in recent years, has increased many times. The mining industry today faces the problem of recovery from ores of a quality found only on the dumps of other years. Hence it has become incumbent upon the engineer to revise his standards of pay-ore and work in closer co-operation with the metallurgist than heretofore. The metallurgist, by the same token, has been forced to revise his more liberal methods for the treatment of high-grade ores and study the economy of vastly inferior orebodies. Improved methods of metallurgical treatment are salvaging the mill-dumps of a few years past. The perfecting of leaching, flotation, magnetic, electro-static, and volatilization processes has proved many of our great deposits of low-grade material to be veritable bonanzas, besides maintaining the country's production of the non-ferrous metals. The new era in metallurgical treatment, particularly in ore-dressing, has practically revolutionized metallurgical machinery. The development of oil-flotation has been materially advanced by the improvements in fine-grinding machinery. The rod-mill is perhaps the latest development in this field. Fine-grinding machinery brought the development of such accessory machinery as slime-tables, vanners, and thickeners, until today our mill-tailings, in the majority of cases, are almost exhausted of valuable mineral. The prospects for the young engineer in metallurgy are indeed bright. With the successful treatment of low-grade deposits of the common metals, the successful treatment of the rare-metal ores is assured. The rare-metal industry is as yet in its infancy, yet such metals as vanadium, tungsten, molybdenum, uranium, columbium, tantalum, thorium, and

cerium have created a demand for them on their merits, and will soon cease to be rare. Their industrial application in special steels (as an alloying element) has produced most remarkable and gratifying results. The rare-earth steels are vastly superior to the carbon-steels in strength and toughness, and, in this day when the industrial slogan is 'increased production', their value cannot be overestimated.

The electro-metallurgical industry presents a splendid opportunity to graduates in metallurgy. With the utilization of our water-power resources for the production of electricity, electro-metallurgy has made great strides as an industry in the United States. At the present time this industry is centred about Niagara Falls, from which the essential energy is derived. Norway and Sweden perhaps were the pioneers in the development of electro-metallurgy, and much of our present knowledge of the science has come from them. Electro-metallurgical processes are rapidly replacing many of the earlier methods for the recovery of metals from their ores, manufacture of refractories, chemical reagents, alloys, and the refining of metals. Electro-metallurgy has revolutionized the manufacture of chlorine, sodium hydroxide, aluminum, calcium cyanamide, calcium carbide, and the ferrous and non-ferrous alloys. The electro-metallurgical processes for the refining of the precious and some of the base metals are the most efficient known. The elimination of the smoke nuisance, the recovery of valuable fume from smelter gases, and the removal of water from petroleum products have been accomplished through electro-metallurgical means.

A science that has but recently been recognized industrially is metallography—the study of metals under the microscope. Through its application the physical properties of pure metals and alloys may be determined, and such heat treatment prescribed as will produce a desired result in the internal structure of the material. This is one of the most highly specialized fields in metallurgy, and the graduate would do well to gather experience in pyro-metallurgy and electro-metallurgy before confining himself to metallography.

There is one field of mining to which the young engineer is likely to pay scant attention, and that is the mining of the non-metallies, such as clay, gypsum, sulphur, salt, asbestos, spar, and building-stone. The mining methods used in the recovery of such material are essentially simple, yet there is much room for improvement in the manner in which many of our quarries and clay-pits are operated. The attitude of the quarry-man toward more efficient methods is slightly antagonistic. So long as he is marketing his product at a profit (usually a liberal one), he sees little reason to install a more efficient system of recovery. Here is an opportunity for missionary work. The young engineer is likely to regard the recovery of non-metallies as a less lucrative, not to say less fascinating, occupation than the recovery of metalliferous materials. That is a wrong impression.

Now we shall consider a new child of the mining industry, oil-shale. From present indications it will not

be long before the exploitation of oil-shale will be an industry in itself. Here is a project the development of which demands the intelligence of a broad-gauge engineer, thus exhibiting a goal to which every young engineer should aspire. This field is not confined to the specialist in any one phase of mining. The geologist, oil expert, miner, and metallurgist must each contribute his intelligence to the solution of the oil-shale problem. The geologist must locate and work out the structure of the shale deposits; the miner must remove the shale and get it to the mill economically; the metallurgist, in collaboration with the chemical engineer, must develop and design the roasters and retorts to recover the products of distillation; the oil expert and refiner must produce marketable hydrocarbons from the crude shale-oil. The entire process must be carried out at a cost that will permit the oil-shale product to compete with the well-oil product in the open market. At the present time it is debatable whether oil-shale has won its spurs as an industry. Though it seems inevitable that the exploitation of oil-shale will evolve from the experimental stage into a healthy industry, it has not yet assumed proportions of sufficient commercial magnitude to warrant the appellation 'industry'. At the present time, when capital seems to be taking an interest in oil-shale and extensive experimental work is being carried on, the prospects for the young engineer fortunate enough to find an opening seems very favorable.

I might mention the field afforded the mining engineer by manufacturers of mining and metallurgical machinery. It is obvious that the young man trained as a mining engineer, and possessing a faculty for salesmanship, may find his services of no mean value to producers in this field. 'Constructive selling' is more than a catch-phrase. It is reasonable to believe that such a man, trained in the value of mechanical units and systems, and familiar with mining and metallurgical processes, would be more than an ordinary salesman, and would be received with more welcome and less skepticism by the industry than the man trained merely to sell machinery.

In the early days of mining in the United States it was not difficult to interest capital in mining projects. Unfortunately the capital so readily acquired, in many cases, was quite as easily lost or wasted, till today the question of financial support seems to be the *bête noire* of the industry. The capitalist has ceased to take romance as security; he demands facts and figures, and management. Ultimately, the most important element to a mining engineer's success is his ability to manage a mining property efficiently. There comes a time in his career when the responsibility of spending someone else's money devolves upon him, and by the manner in which he spends it—by the results achieved—shall he be judged. The opportunity to spend another's capital judiciously seldom comes twice. Management is largely a matter of spending and conserving funds, judiciously. The use or abuse of the funds rests upon the engineer's business training and financial acumen, together with his com-

prehension of the physical factors involved. Hence it is important that the young engineer become not too absorbed in the technical aspects of mining, to the detriment of his economic intelligence.

Many a technical graduate has accepted his first position in some field of endeavor other than that for which he has prepared himself while at college, pending a desirable opening in the field he preferred. After applying himself to his supposedly temporary position for several months, he may find his interests so absorbed that his original aim is forgotten or obscured. Perhaps while working in this position he has married, and the business of meeting new obligations and responsibilities is taxing his resources to such an extent that he hesitates to resume his original course when the opportunity is at hand. Such a state of affairs may or may not be unfortunate. Subsequent developments in his work, which he has ceased to term temporary, may reveal an element of immaturity in his earlier decision, and the young man may be grateful to Chance for so altering his point of view as to present his early choice of fields in its true aspect.

RUSSELL H. FRASER.

Central City, Colorado, October 12.

On Technical Writing

The Editor:

Sir—I was glad to see, in the review of the book by Professor Brewster, of Columbia, on technical writing, a recognition that the supreme purpose of writing is to convey a meaning, and that in some cases errors and poor construction are allowable, when the meaning is thereby more briefly or forcibly conveyed.

There is an occasional gem that is so exquisitely done that it is a pleasure to read it just for the literary charm. However, in most of the reading a mining engineer is required to do, it is a relief to have the author convey his meaning in the fewest possible words, whether or not he obeys or breaks all the rules of writing. Human knowledge has expanded to where it is impossible for one man to know it all. Those who have a real message to deliver are apt to be short on literary style; and those who are long on literary style are apt to be short on message.

The stress that has been laid on literary style, led by the editor of the 'Mining and Scientific Press', one of the exceptional men with both literary style and message, might result in scaring out of technical writing some of the writers of real messages imperfectly delivered, and filling their places with better-written nothings. In many recent cases a one-page message has been expanded into eight pages in literary style which most engineers do not read even when on a subject or job in which they have reason to be particularly interested; so that it is a relief to see a little recognition of the fact that the purpose of language is to convey the meaning in the most direct manner possible, even to the extent of breaking some of the cherished rules of style.

Perhaps co-operation between the practical and the

literary man would be a solution of the problem. Before publication, the practical man should give the effusions of writers possessing literary talent the necessary brevity demanded from an engineering viewpoint; the practical man's message should be subjected to the literary artist, who should be allowed full play whenever he can say as much in as few words.

The fact that few engineers are reading many of the voluminous articles that are handed out today as the literature of the profession is recognized by both the editors of the 'Mining and Scientific Press' and the 'Engineering and Mining Journal', in their criticisms of A. I. M. E. publications. I wonder if they would be surprised to learn how few of their own subscribers ever read some of the lengthy voluntary contributions upon which they themselves have to depend. Many of these articles would be interesting if the author had not expanded a one-page message into eight pages of literature for the prestige he thought it would give him to go into print as the author of a lengthy article.

Conveying the meaning in the fewest possible words is perhaps more important to the profession today than so-called literary style.

PAUL R. COOK.

Rolla, Missouri, October 10.

[We appreciate our correspondent's impatience at the wordiness of some of the articles he finds it necessary to read, and we agree with him that the main purpose of writing is not the expression, but the communication, of ideas. However, the conveyance of thought is rarely effected by writing that is marked by errors of phrasing and by bad construction; on the contrary, the most careful phrasing and the best construction are required for the purpose. Nevertheless, a style that is prolix is not good. We reject many articles that embalm a few ideas in a mass of words, knowing that our readers are too busy to read such stuff. An article that is deficient in literary style but rich in useful ideas is always welcome, and it is our privilege to help the author in conveying his message, by revising his manuscript, not so as to kill its originality but sufficiently to enable him to complete the transfer of his ideas to our readers.—EDITOR.]

Failures Due to Lack of Capital

The Editor:

Sir—From time to time you have sounded a warning in your editorial columns against speculating in shares of mining companies launched by unscrupulous promoters. This is well; it tends to discourage those who prey on public credulity, and at the same time helps those of your readers who are not experienced in mining, to distinguish a legitimate mining report from a flamboyant prospectus.

It is quite common to hear that "as much gold has gone into the ground as ever came out of it". It is true that innumerable mining ventures have proved failures, the sad part being that many of them had merit. The reason for failure was lack of capital. It seems to me that it might be well to warn the layman, the young

mining engineer, and even the older engineer, experienced in his profession but not in finance, of the danger of undertaking any mining enterprise without first providing ample funds to carry it to a producing stage, and sustain it during times of depression.

In this respect mining can be compared with commercial enterprises; and it is illuminating to note that in the year 1913, when conditions in the United States were not far from normal, Bradstreet's figures as to the cause of failures show 24% due to lack of capital, while in 1918, 30.8% was due to this cause; the next highest being incompetence. I venture to say that failures in mining due to lack of capital would show a much higher percentage than in industrial enterprises, due to the difficulty of anticipating the requirements.

In times of great inflation in metal prices, people become most interested in mining. Many new enterprises are started; and just about the time they reach the producing stage, or even before, the tide turns and leaves them stranded. At the present time, with copper selling at the lowest price in many years; with huge stocks of the metal awaiting a purchaser, and most of the big producers closed down entirely or running at low capacity, the number of wrecks in this branch of the industry must be very large.

The next important cause of failure in mining is the disregard of our position in the minor or major trade cycle at the time the enterprise is started. Referring to the diagram from 'The Annalist' of July 4, it will be seen that we have completed two major cycles and have entered a third. Commodity prices will probably be on the decline for a long period of years. How will this affect mining? It will certainly be a great benefit to gold mining. The value of the product being fixed, the lowering of costs will continue to add to the profits for many years. This is the time to clean out the old drifts, and get things in shape to take advantage of cheaper money next year. While the present trend of prices is all in favor of gold mining, what would have been the fate of an enterprise initiated seven or eight years ago?

In exploiting the baser metals, we are more concerned with the minor trade cycles. Never in our history have we had such a drastic cut in prices of raw products. On the surface, the prospects for mining of metals other than gold are not cheering, but the reaction will follow as surely as day follows night. The advantage of starting a mine now is that it will have ahead a number of years in which to fortify itself against the next relapse in metal prices; whereas if left until later, full production may not be reached in time to reap the benefits of rising prices.

The criticism may be raised that I am discouraging men of small means from engaging in mining. In a way I am, unless they are associated with mining men with large capital, who may be willing to furnish the best technical advice and the money to see it through.

Mining is an alluring form of speculation, and appeals to many men in and out of the profession. The motive of speculation is profit, but how many who speculate in

mines do obtain a profit? I offer the suggestion to those who care to speculate, that the purchase at this time of shares in mining companies that have a satisfactory record as dividend-payers, is sure to give them a handsome profit within the next two or three years. To show the possibilities of this form of speculation in mining, let us take the record of 20 copper stocks. The average price in September 1907, a panic year, was 28.6; August 1909, 60.8; December 1914, 31.9; November 1916, 66.5; and the average now about 23.5. Copper stocks are certainly bargains today.

If one will rely on averages by distributing widely, buy the shares outright and sell them on the next bull market, he is almost sure of doubling his money, and within the next two or three years.

DOUGLAS WATERMAN.

Havana, Cuba, September 28.

Non-American Issues

The Editor:

Sir—In your issue of September 3, Mr. Crocker deprecates the control of American politics by audacious minorities and proposes a new method of voting for officials, called the Compromise method, as a remedy. By this scheme each voter is required to vote for one more than half of all the candidates nominated for each office with the object of electing one of his own selections. This would undoubtedly elect a candidate of a non-partisan hue—a compromise candidate who would neither be the first love nor the first hate of any voter. Though such compromise selections might be less harmful in office than the agents of unscrupulous minorities, they would be far from ideal. While less likely to be knaves than the officials chosen under the present plurality system, they would be even more likely to be fools. For few candidates of any force of character or aggressive ability could ever get elected by the compromise method, which would constantly tend to elect individuals of so colorless a personality as to be obnoxious to nobody—in other words, nonentities.

A far better method for avoiding the control of politics by non-American minorities, or indeed by any minorities at all, however worthy, is by means of proportional representation, which is designed to make all legislative bodies a miniature, in their political views, of the voters that choose them.* The present system of electing legislatures, by choosing one candidate from each geographic division, has three serious defects: first, the fortunate candidate may have received only a plurality of votes; second, all those who vote against the winner will enjoy no representation in the deliberative body; and third and worst, in any geographic division in which two parties are almost equal in numbers, a small organized minority of independent voters can determine the election by merely throwing its whole vote to either of the two party candidates. This weakness of our representative system has long been known to political stu-

dents, and accounts for the disproportionate influence on legislatures of such compact minorities as the Grand Army, the Federation of Labor, and the Anti-Saloon League, without mentioning the bodies of hyphenated voters so feared by Mr. Crocker.

The change from the present unfair geographical representation to the equitable proportional system is a simple one, and would undoubtedly have made rapid progress in the United States—as in other leading nations—had it not encountered the opposition of selfish interests, probably the most influential of which are the Democratic political machines of the South, who see no practical way to prevent the election of a large number of negro legislators should proportional representation be adopted.

To establish proportional representation for the election of the Federal congressmen of any State, the first step would be its division into a number of large districts, each electing three or more candidates, to replace the single-member districts now in vogue. Then in a district which had seven Congressmen to elect, and contained 150,000 Republicans, 100,000 Democrats, 50,000 Farmer-Labor, and 50,000 Socialists, the new voting system would ensure the election to Congress of three Republicans, two Democrats, and one each from the Farmer-Labor and Socialist parties. For achieving this accurate proportional result, four principal systems have been devised: the Hare, the List, the Japanese, and the Gore. Of these, the List system is well adapted to party nominations and is a favorite in Europe, being used in Belgium and France. The Japanese is the simplest of all, as a voter has to vote for only one of each group of candidates. Although this system is used for selecting the Japanese congress and is perhaps the best for an ignorant electorate, it has the serious objection that it may result in the winner with the most votes receiving several times more votes than the winner with the least.

All things considered, the Hare system seems the one best adapted to American conditions. It is now being introduced by an active organization,† which has already secured its adoption in the cities of Ashtabula, Ohio, and Sacramento, California, as well as in many smaller electorates. Under this system all a voter has to do is to write as many names on his ballot as there are officials to be elected from his district, and to place opposite each name a number indicating the order of his preference. In counting the vote, there are first declared elected all candidates who receive enough first-choice votes to 'qualify'. If there are five legislators, for example, to be elected from a district in which 50,000 votes are cast, the minimum qualifying number would be 10,000. If insufficient first-choice candidates obtain a sufficient qualifying vote their surplus vote is distributed by fixed rules to second-choice candidates, and so on, until the requisite number of votes is obtained to qualify the required five officials for election.

The proportional principle, of course, applies only to

*American Proportional Representation League, Franklin Bank Bdg., Philadelphia, Pennsylvania.

*'Proportional Representation', by J. H. Humphreys.

the election of representative or policy-determining bodies. Administrative officers obviously should be elected by majority vote, if they are to be chosen at the polls at all. According to views accepted by many political thinkers, chief administrators should all be appointed by the elected representative body and the minor administrators selected by the chiefs under civil-service rules to prevent the interference of political considerations in their appointment. If, however, such officers are elected at the polls, they are better chosen by the application of one of the modern majority systems (using the 'preferential ballot' of the Ware, the Remsen, the Bucklin, or the Nanson variety) that have been successfully employed in Australasia, rather than by our prevailing plurality system.

Not only will the adoption of proportional representation remove the undue influence on politics of organized minorities—even the racial ones so feared by Mr. Crocker—but it will safely permit the extension of government ownership of public utilities in many desirable directions. We had a taste of the danger of government ownership under the present geographic system of electing Congressmen in 1916, when the American Federation of Labor was able to force the Congress to pass the unfair Adamson bill. Whenever the Congress is chosen by proportional representation, the Federation will be unable to dominate more Congressmen than its vote can elect and at present membership that would mean less than 15% of the total House of Representatives.

ROBERT B. BRINSMADE.

Charcoal and Cyanidation

The Editor:

Sir—Referring to your editorial on this subject in your issue of October 8, the plant referred to by you as being the first to use this method of precipitation is probably the South German at Maldon, Victoria, Australia, which was controlled by the late W. B. Gray. This method was also in use at the Lake George mines, New South Wales, in 1899-1900. The same Mr. Gray was responsible for its installation there. I do not remember the quantity of solution precipitated daily at the latter plant, but there were 144 tubs such as you describe, and, owing to the silver in the ore, it was necessary to have 6 in each row. The system had all the drawbacks you mention. I have also seen this method in use at the Talisman mine in New Zealand on waste solutions many years ago. In 1915, before I knew anything of the experiments of Messrs. Moore and Edmunds, I suggested the use of charcoal dust in Merrill presses to an eminent San Francisco metallurgist, but he said it had been tried and found wanting. It may not be generally known that, for many years prior to 1912, lump charcoal was used to precipitate gold from chlorine solutions at the Mount Morgan gold mine, Queensland, Australia, and, I believe, was found satisfactory. It was placed in square concrete tanks, and I have been told

that the gold was visible on the outside of the charcoal lumps, which I have not noticed in using charcoal for cyanide solutions.

While on this subject, it is interesting to recall that in the old days of dry crushing by stamps at the Waihi gold mine, New Zealand, the ore was first dried in vertical kilns in the hillside above the mill, ore and firewood being placed in alternate layers. Naturally there was much charcoal mixed with the ore when it went to the stamps. The whole product was conveyed to shallow leaching-tanks and cyanided, but I never heard of any trouble arising from premature precipitation of gold and silver on charcoal in the leaching-tanks, and the extraction of gold was about 90%. Possibly the fans, which were used to draw off the dust from the stamps, removed most of the charcoal, but even then this dust was collected in bag-houses and probably cyanided, with what result I do not remember. We are all familiar with the trouble from graphite in cyaniding ore at the Ashanti mine in West Africa. Isn't there similar trouble in cyaniding slime in Amador county, California, or has it been overcome?

WILLIAM MOTHERWELL.

Indicative Plants

The Editor:

Sir—From early times it has been noted that the soil overlying mineral veins is covered by special vegetation. Can any of your readers give me personal accounts of his experience on the matter?

Correspondents desiring to communicate with me should address their letters as follows:

R. VAN AUBEL,
September 22. 120 Chaussée de Courtrai,
Gand, Belgium.

It has long been known that on prolonged contact, oils of all types may produce lesions of the skin, affections which have been described by various observers under different names, states the 'Journal of Industrial Hygiene'. C. G. Page and L. D. Bushnell, who suggest the name of 'oil folliculitis' for the disease, have investigated the bacteriology of oils which are commonly considered to be its cause, and have concluded that the most serious skin diseases are probably due to the oil acting as a carrier of infectious material. To obviate infection, the most important precaution is the exercise of clean habits by the workman. Oils can be sterilized by heating to 70°C. for 20 to 30 minutes, but in practice it is not easy to keep them sterile and free from dust for any extended period. Researches have shown that oils containing ichthyol and those pressed from crude paraffin also produce skin lesions. The addition of germicides to the oils is not satisfactory, but daily filtration and sterilization of the used oils reduce the number of metallic particles present and tend to minimize the danger of bacterial infection.

THE GOLD BULLION MINE AND ITS CLIFF-DWELLINGS

The Gold Bullion Mill and Cyanide Plant, Willow Creek, Alaska

By O. A. Glaeser

INTRODUCTION. One of the most promising regions for the development of small gold-quartz mines in the near future lies in the south-western and south-central part of Alaska, beginning with the well-known Willow Creek district and ending along the northern slope of the Broad Pass region. A number of mines in the Willow Creek district have been steady producers of gold for over ten years, and all indications point to an increase in mining activities in the near future. Since the beginning of construction on the Government railroad that serves these districts, an active interest has been shown in the Broad Pass region. Although prospects are numerous, none have so far developed into producing mines; but sufficient work has been done to show that the region contains a number of well-mineralized areas that are worthy of exploitation.

TRANSPORTATION. Even with railroad facilities, transportation is a problem that will always be a burden to the mine operators. The Alaskan Road Commission is doing all it can to assist by constructing roads; but the work is handicapped by the extremely short summers. The most accessible mines in the Willow Creek district are now reached by road, but many miles of difficult

road building must yet be done. The mines are about 25 miles north of Wasilla, the nearest station on the Government railroad. In the past it has been the practice to freight, over the snow, all machinery and supplies that are not affected by low temperature. This is cheaper than bringing them over the road on wagons, or by pack-horse where no roads exist. Transportation practically ceases for a period of about two to three weeks in May, when the snow is too deep for wagons or pack-horses and too soft for sleds.

LABOR. The labor problem is insistent, owing to the fact that employment is seasonal, and also because the old-school miners who were dexterous with the hammer are hard to find. The journey to the district is an expensive one, the working season is short, and living conditions are none too good; a considerable labor turn-over is inevitable during the season. An attempt was made to improve conditions by providing better quarters and better wages. Miners, before the War, were paid \$3.50 per day and board. This was increased to \$4 per day in 1918; in 1919 a bonus of \$1 per day was added, payable at the end of the season. This plan, however, was never strictly followed; men received their bonus on leaving

the employ of the company. Moreover, this type of bonus system is not satisfactory. The men do not seem to understand it, and discontent has always been the dominant feature of pay-day. Technical help is excessively expensive. Owing to short-time employment, the salaries of technical men are comparatively high, and all traveling expenses must be met by the company.

WATER SUPPLY. Perhaps the biggest problem confronting a mill operator in the district is water supply. The fact that properties have so far only been operated during the summer season is largely due to the scarcity of water for seven months of the year. Up to this year the only source of power for milling purposes has been that derived from creeks. However, one of the operating companies is installing a power plant this year. Whether it will be found feasible to operate during the winter season is doubtful. In the past it has been the practice to open camp early in May, employ a small crew of men, and get all equipment and machinery in shape for the season's run, so that operations can start with the first available supply of water, which is usually plentiful during the months of June and July. If the rainfall is light during these months, a water shortage is sure to come in August, resulting as a rule in a temporary suspension of milling operations, either wholly or in part, for a period of one to three weeks. Once the dry spell is past, steady operation continues until October, when the cold weather cuts off the water supply.

GOLD BULLION MINE. The Gold Bullion property is situated near the headwaters of Craigie creek, a tributary of Willow creek, from which the district gets its name. Wasilla, on the Government railroad, is the nearest railroad station; from here a wagon-road leads for 16 miles into the Talkeetna mountains. A 12-mile horse-trail covers the remaining distance to the mill.

The croppings of the Gold Bullion mine are near the summit of the ridge that separates the upper valleys of Craigie and Willow creeks. The mine is at an elevation of 4500 ft.; the mill in the valley has an elevation of 3050 ft., or 1450 ft. below that of the mine. A jig-back tramway, having an hourly capacity of three tons, deliver the ore to the mill. The ore is free-milling gold quartz, occurring as fissure veins in granodiorite. Qualitative tests show the presence of iron, copper, lead, arsenic, and minute quantities of mercury.

GOLD BULLION MILL. At the mill the ore is delivered from the rope tramway into a large receiving hopper, then passes over grizzly-bars set to pass $1\frac{3}{4}$ -in. material. The oversize is fed to a 7 by 9-in. Blake-type jaw-crusher. The crushed ore and the undersize grizzly product go to a 150-ton storage-bin. This bin is tapped by three chutes, each of which delivers ore to a Challenge feeder. The mill has a total of 12 stamps, arranged in two batteries of five stamps each and one of two stamps. The two five-stamp batteries are of the front-discharge type; the two-stamp battery discharges its pulp in front and on the sides. The screens used are 30-mesh, standard-gauge wire. The stamps weigh 1000 lb., drop 95 to 105 times per minute, and have a duty of 4 tons per stamp per 24

hours. The pulp passes over amalgamating plates, one for each battery, having a surface area of $4\frac{1}{2}$ by 10 ft. The plates are dressed twice each 24 hours. After passing over the plates, the pulp flows through amalgam-traps to a drag-classifier, where a separation of sand and slime is effected. Spitzkasten classifiers were formerly used, and little attention was paid to good classification, the principal object until recently having been to obtain a sand sufficiently free from slime for treatment in the leaching-plant. The results were that both sand and

slime were contaminated the one with the other. Screen-sizing tests (see Table I) show that only 68% of the total feed to the leaching-plant is plus 100-mesh. On the other hand, the slime contains about 8% of sand. Closer classification will be attempted hereafter, by producing a cleaner sand in the mill-classifier, and by treating the

SLICING SLIME

slime with a Dorr duplex drag-classifier before it enters the slime plant.

The sand from the drag-classifier is delivered by launders to a Wilfley concentrating table. The concentrate is stored until sufficient has accumulated for treatment in the cyanide leaching-plant. The table tailing is sent to a bucket-elevator which lifts it to such a height that, with the addition of some water, it will flow in launders to the leaching-vats.

Mill feed and tailing are not sampled for assay. The concentrate from the Wilfley table assays \$127.74 per ton.

LEACHING-PLANT. This plant was built six years ago. It consists of five 30-ton and one 35-ton leaching-vats, one 30-ton sump storage tank, one 20-ton solution tank, and two 9-compartment zinc-boxes having a combined capacity of one ton of solution per hour.

Owing to climatic conditions, the cyanide plant must cease operations several weeks before the mill does. The sand from the mill is then sent to settling-ponds, and stored for treatment during the following summer.

The vats are filled either directly from the mill, in which case the sand is sluiced down a wooden launder to the vats, or from the sand pond, from whence it is hauled in a 1200-lb. ore-car, and hoisted up an inclined trestle to a track above the vats where it is dumped. The mill output is sufficient to fill a vat in 20 hours. The

overflow water contains a considerable amount of slime. To save this for subsequent treatment it is carried in a launder to the slime-settling ponds. Fourteen hours is required to fill a vat from the sand ponds, requiring the labor of two men. When the vats have been filled with sand they are drained of water; the time consumed is at a maximum in the case of mill sand, about 18 hours. Cyanide solution is then pumped on; the first treatment is with a strong solution containing 5 lb. (NaCN) per ton of solution; the second treatment is a weak solution, 3.5 lb. (NaCN) per ton of solution.

The strong solution is tested for cyanide and it is drawn from the vats; when it shows a cyanide strength of 1 lb. per ton it is turned into the zinc-boxes. Tests have shown that large quantities of water can thus be further drained, which would only dilute the cyanide solution and increase the bulk of it beyond necessary requirements. Treatment lasts about three days, after which the vats are drained of all available solution and the residue is sluiced through a central opening. The tailing is disposed of by letting it run into Craigie creek, which carries it away.

DETAILS OF OPERATION OF LEACHING-PLANT. The ore contains sulphate salts, and a considerable quantity of lime is needed. This is added in two ways; vats filling with pond sand receive about two quarts of a heavy milk

MILL AND CYANIDE ANNEX, WITH SLIME-POND IN FOREGROUND

of lime with each car of sand, making a total of about 50 lb. of unslaked lime per vat; vats filled from the mill receive when full 72 lb. of unslaked lime in the form of a heavy milk of lime. The difference in the quantities of lime used is due to a natural leaching process that goes on in the sand ponds into which water finds its way continuously. The strong solution constituting the first treatment has a protective alkalinity of 4 lb. per ton of solution, which is brought up to strength by the addition of caustic soda. The cyanide strength is kept up to 5 lb. per ton. It has been found by trial that about 16 tons of strong solution, added as quickly as the sand will take

it, is the most effective amount to use. This treatment usually takes about 18 hours. The sand is allowed to drain for some hours, after which a weak solution treatment is started. This solution is taken from the sump below the zinc-boxes, and averages about 2.5 lb. protective alkalinity, and 3.5 lb. cyanide. This treatment is as nearly continuous as possible for about 18 hours. The sand is then permitted to drain for 12 hours, when it is sampled for assay and sluiced out. About three hours after the first of the weak solution has been pumped on the sand, the pregnant solution is shut off at the storage, or at the distributing barrel at the head of the zinc-boxes, and turned into the storage tank, where it is standardized for strong solution. This system is used for two reasons: first, to reduce the amount of solution going through the zinc-boxes, and, second, to keep the solution going through the zinc-boxes as high in cyanide as possible. To assist in the latter object a sweetener barrel containing a 1.5% cyanide solution has been placed above the distributing barrel into which the solution drips very slowly. This arrangement has decreased the gold content in the precipitation tailing from 0.05 oz. per ton to 0.02 oz. per ton, or 60%.

SAMPLING. Two samples are taken of each vat of sand treated. The head sample is taken before any solution is added. The tail sample is taken just before sluicing the sand out of the vat. A representative sample is obtained by the use of a sampling rod, which is made from a $\frac{3}{4}$ -in. pipe 6 ft. long by splitting it along the seam for a distance of 5 ft. The upper end is threaded, and a horizontal cross-arm is attached. Six rod samples constitute one sample that weighs about three pounds.

ZINC-BOX PRACTICE. Two zinc-boxes of nine compartments each are used, with a combined capacity of one ton of solution per hour. The boxes are dressed daily, and the zinc is washed every second day. The precipitate is screened on a 40-mesh screen; the undersize is poured into a canvas filter. The precipitate left on the canvas is put into 5-gal. cans and stored for refining. The oversize is short-zinc, and is returned to the zinc-boxes. The direct results of this practice is a high-grade precipitate assaying \$51.11 per pound. The filtrate from the canvas filter is piped to the sump tank. At the end of each month the precipitate is weighed and sampled for assay. The moisture content is determined, and the value of the raw precipitate on hand calculated. The precipitate is refined in a small crucible furnace using gasoline as fuel, the bullion assaying about \$17 per ounce.

Extraction for the season averaged 71.26%. This is lower than average leaching-plant practice and the reason can be best explained by showing the results of a representative screen-sizing test.

Table I—Screen-Sizing Test on Sand Feed to Cyanide Plant
Assay of sample, \$7.23 gold per ton

Mesh	Actual, %	Cumulative, %	Gold content Per ton	%
20	0.4	0.1	\$11.58	0.8
30	11.4	11.5	6.20	14.5
40	8.0	21.3	6.20	8.1
60	37.0	58.3	6.20	37.1
100	8.5	68.0	6.20	8.0
150	10.0	77.8	6.20	10.0
200	9.5	87.3	7.86	12.2
-200	6.0	100.0	7.86	8.3

Table II—Screen-Sizing Test on Sand Tailing from Cyanide Plant
Assay of sample, \$1.65 gold per ton

Mesh	Actual, %	Cumulative, %	Gold content Per ton	%
30	15.2	15.2	\$4.55	26.9
40	7.8	23.0	3.72	11.3
60	35.2	58.3	1.65	22.3
80	13.8	72.2	1.04	5.5
100	9.8	82.0	1.04	3.9
150	11.0	93.0	1.04	4.3
200	2.6	95.0	2.07	21.0
-200	5.0	100.0	2.48	4.7

Table I shows that 21.3% of the total feed to the vat is plus 40-mesh, and contains 23.4% of the total gold; also that 22.2% is minus 100-mesh, which is considered slime. This contains 30.5% of the total gold.

Table II shows that 38.2% of total gold is contained in the plus 40-mesh material and 30% in the minus 100-mesh product.

These figures prove that a higher extraction can be obtained by replacing the 30-mesh screens with those of 40-mesh; and, by closer classification eliminating the slime, which is nearly impervious to the solution, thus obtaining better circulation through the sand.

CYANIDE SLIME PLANT. This plant was built in the spring of 1920. All operations attempted were of an experimental nature. An outline is here given of the method most applicable to the ore with the equipment on hand.

The material to be treated in this plant is an accumulation of slime collected in large ponds for some years. Long and continuous settling has made it very coriaceous and consequently hard to break. This is accomplished with high-pressure water (400-ft. head), using a $\frac{1}{4}$ -in. nozzle in order that a minimum amount of water be used, and the pulp remain as thick as possible. A 3-in. Krogh centrifugal pump lifts the pulp 15 ft. into a Dorr duplex classifier. The sand is sent to the leaching-plant, the overflow to a 34-ft. Dorr thickener. Here the pulp is to be thickened to a 1:1 ratio, but under actual operating conditions it may be found impossible to carry this out in one step without a great reduction in tonnage. An inverted siphon delivers the thickened slime to the first agitator, which is used as a mixer, sufficient barren solution being added to increase the ratio of solution to solids to 2:1. Sufficient slaked lime in the form of a milk is also added to give a protective alkalinity of 1 lb. per ton of solution. The overflow from the first agitator passes into the second, where sufficient cyanide is added to bring the solution up to a strength of 1 lb. per ton. The pulp passes through the third and fourth agitators, is then raised 5 ft. by means of an air-lift and delivered into the loading-well of the second 34-ft. Dorr thickener. The thickened pulp is drawn by gravity to a 12-ft. Oliver filter. The cake is considered waste and drops into Craigie creek. The solution is delivered by a centrifugal pump to the pregnant-solution storage tank. The overflow from the second thickener is elevated 3 ft. by means of an air-lift, and is delivered to a clarifying vat. The gold-solution passes through the zinc-boxes. The barren solution flows by gravity to the barren-solution tank, and thence back to the first agitator. It has been found necessary to throw considerable solution away, as there was an excessive accumulation due to the fact that the pulp

was not thickened sufficiently in the first thickener. This almost doubled the consumption of cyanide. The gold loss, however, is small; precipitation is good, only 0.007 oz. of gold per ton being left in the solution.

Leaching-Plant Operating Costs

		Tons treated, 2120			
Supplies	Pounds per ton	Cost per pound, cents	Total cost	Cost per ton	Cost per oz. gold recovered

Lime Consumption in Cyanidation

By Ralph W. Perry

High lime consumption in cyanidation is often ascribed to the sulphates, soluble and insoluble, in the ore treated, oxidation products of sulphides being present in most cases, and also being produced to some extent during cyanidation. Lime consumption is usually stated in pounds or kilogrammes per ton of ore, but the grade of lime is seldom specified; this varies, in my experience, from 15% to 75% available CaO (water soluble) so that published figures of lime consumption are of little value except to emphasize the importance of paying attention to the purity of the material used.

A case recently came to my notice in which there was a high lime consumption. Sulphides or sulphates were present in the ore in barely distinguishable quantities, so small in fact that no part of the lime consumption could be attributed to their occurrence, and an investigation showed that ferrous carbonate was present in appreciable amounts and was being oxidized during the treatment to ferric hydrate or possibly to hydrated ferric oxide. This oxidation was accompanied by a corresponding precipitation of calcium carbonate if lime was present in sufficient quantities, the iron otherwise combining with the cyanide to form sodium ferrocyanide.

In the absence of lime the ferrous carbonate apparently reacts in a manner similar to ferrous sulphate, but, being an insoluble salt, the reaction proceeds much slower, according to the following equation:

The formation of sodium carbonate was proved in tests in which caustic soda was used instead of lime. In the presence of lime the probable reaction is:

In the absence of ferric carbonate the carbon dioxide radicle combines with whatever element is available. This oxidation of ferrous iron also explains why air is required in so much greater quantity than is needed, theoretically, for the solution of gold and silver.

The ore in question is that from the Veta Colorado mine, near Parral, Mexico, where the Alvarado Mining

Co. and the Veta Grande unit of the American Smelters Securities Co. are operating cyanide plants. The cause of this consumption was discovered while I was conducting cyanide tests at the Veta Grande plant, but the same condition exists at the Alvarado plant. The ores under investigation were all from above water-level, and were of the following approximate analysis:

Insoluble	75.00	Pb	0.25
Ferric iron	3.00	Cu	Trace
Ferrous iron	2.00	Zn	1.25
Al ₂ O ₃	4.00	Mo	Trace
CaO	4.80	Sb	Trace
Mn	0.60	S	0.08
Mg	0.20		

The ore varies from a slightly silicified andesite to nearly pure quartz or calcite, the more highly silicified ore being characterized by a higher iron content and a lighter color than the predominant surface ores, which are of a deep-red color (hence the name of the vein), in spite of their relatively low percentage of iron. The actual lime consumption in the plant varies with the length of treatment, but not in proportion; the consumption decreases as the amount of ferrous iron present becomes smaller. Sodium ferrocyanide is not formed in the treatment of these ores so long as lime is present in amount above 0.005%. The solutions at the Veta Grande plant showed no trace of ferrocyanide after being in continuous use for over a year.

Results from the ordinary tests for alkali loss include the lime consumed by ferrous carbonate, so that the only benefit resulting from a knowledge of the cause would lie in an appreciation of time as an influence on the amount of lime used. Shortening the time of treatment decreases the quantity of lime required, and this may be an important item, especially where low-grade lime must be used.

In discussing the de-aeration of solutions before the Chemical, Metallurgical and Mining Society of South Africa, Thomas B. Stevens drew attention to the work that has been done in Western Australia in connection with what is known as the Coolgardie water scheme. The water is pumped from Nundaring to Kalgoorlie, a distance of 350 miles, through a 30-in. diameter steel pipe; in traveling this distance it is pumped eight times. Early in the life of the main there was a rapid increase in friction, and the inside of the pipe became heavily coated with rust nodules. A committee of experts who investigated the trouble advised that lime be added to the water, and also that it be de-aerated. The addition of lime alone was first tried and was found to be inadequate. A de-aeration plant was then installed, and this has been so successful in stopping the corrosion that the use of lime has now been discontinued. The de-aerator is of the mechanical type, the water being sprayed into a tower and subjected to vacuum, 90% of the dissolved oxygen is extracted, and the remaining 10% is found to be absorbed in the first 30 miles of pipe. The water as delivered to the mines at Kalgoorlie shows no oxygen by the alkaline pyrogallate test. The amount of water delivered is 2,000,000 gal. per day.

Treating the Copper Impurity in Lead Ores

By D. C. McGruer

*The question of dealing with the small quantities of copper found in many purchased ores became a factor of importance when the Sulphide Corporation decided to refine its own lead bullion, as the presence of this impurity has a marked effect on the efficiency of the de-silverizing operations of the Parkes process.

The copper is removed from the base bullion by drossing, which collects the copper, and, in addition, some gold, silver, and lead. The drossing of the bullion is done in two stages, at the smelter and in the copper kettles at the refinery. In both cases a 'wet' dross is produced, which is subsequently 'sweated' in a suitable furnace. When 'dry', the dross is raked out and stored until enough accumulates to warrant a run in the small blast-furnace kept for that purpose.

A typical assay of the 'dry' dross is as follows: Gold, 0.3 oz. per ton; silver, 55 oz. per ton; lead, 60-70%; copper, 6.5%; iron, 2.2%; zinc, 1.5%; tin, 4.5%; arsenic, 1.6%; and sulphur, 4.5%. The accumulated dross is treated in a small blast-furnace with the necessary fluxes, producing a low-grade copper-lead matte and base lead bullion. The assay of the matte is approximately as follows: Gold, 0.05 oz. per ton; silver, 30 oz. per ton; lead, 32.2%; copper, 23-25%; iron, 25%; zinc, 3%; antimony, 5.6%; arsenic, 3.3%; and sulphur, 14.4%.

This matte was formerly crushed, roasted, then leached with sulphur, and copper precipitate produced; but, owing to the shortage of scrap-iron, another method of converting the copper into a marketable form was considered. The conversion to bluestone appeared to be practicable; the low-grade matte is crushed through a $\frac{1}{2}$ -in. screen, given a quick roast in the rotary furnaces, then passed over a Dwight-Lloyd machine, and is finally worked up to high-grade matte in a reverberatory furnace. In working the low-grade to high-grade matte, the time of treatment is gauged by the iron content of the charge; when a dip sample shows the iron to be about 2%, the charge is tapped, irrespective of the amount of copper present. The lead loss in fume is high, but provision is being made to connect the reverberatory furnace to a bag-house.

An average assay of the high-grade matte produced is as follows: Gold, 1.125 oz. per ton; silver, 69 oz. per ton; lead, 24%; copper, 47%; iron, 2%; zinc, 2.4%; and sulphur, 17%.

The high-grade matte is crushed in a Krupp mill through a 40-mesh screen, roasted in a 4-hearth hand reverberatory furnace, and then passed to the leaching department for the production of bluestone. The temperature when roasting is between 600° and 625°C., the following temperatures being maintained under working

conditions: No. 1 hearth, 460°C.; No. 2, 532°C.; No. 3, 582°C., and No. 4, 618°C. An average sulphur assay of the roasted product is as follows: Total sulphur, 7.7%; and sulphur as SO_3 , 7.4%.

The copper in the matte is dissolved by leaching with dilute sulphuric acid in a circular agitation-vat provided with a wooden paddle, which is driven by a spur-and-pinion wheel fitted over the top of the vat. Two agitators are in use, for leaching the roasted matte or for purifying the neutral leach liquors. Sometimes one is being used for treating the matte and the other for purifying the liquors, and at other times they are both used for purifying accumulated neutral liquors. The production of a neutral impure liquor takes from 1 to 5 hours, whereas 5 to 15 hours is necessary for purification, according to the quantity of iron present; therefore an accumulation of impure neutral liquor takes place.

In making up neutral liquors, the roasted high-grade matte is carefully weighed, then tipped into the agitator, which has been previously filled to the correct level with water (or acid wash liquors from a previous charge), and a calculated quantity of sulphuric acid. Sufficient acid is added to give a neutral liquor containing 70 to 80 gm. of copper per litre. The temperature of the liquor is kept at about 70°C. by means of live steam delivered to the bottom of the agitator. Samples are taken during the agitation, and a test is made for copper, iron, and sulphuric acid. When there is a sufficiency of copper and when the solution is neutral, agitation is stopped, the steam is turned off, and the pulp is allowed to settle, the clear liquor being decanted and sent to the storage-vat for impure neutral liquors. It has been found that at least three leaches can be made before it is necessary to discharge any residue. The amount of copper in the matte controls the size of the charge to the agitators, as well as the number of charges treated before discharging a residue.

After the third neutral liquor has been decanted, two successive acid washes are given to the residue. Each wash is given about two hours agitation with 5 to 10% sulphuric acid. Live steam is used to raise the temperature to about 60°C. Periodical tests of the wash-liquor for copper and acid are made; and, when no further increase of copper in the solution is shown, the agitation is stopped, the pulp is allowed to settle, and the clear acid-wash liquor is sent to the wash-water storage-vat. From there it is subsequently pumped back to the agitator for the next charge, to make up neutral leach liquors of the required strength. After the second acid wash has been decanted, sufficient water is added to flush the residue from the agitator, through a bottom discharge, into the first of three cone-shaped settling-vats, which are ter-

*Abstracted from a bulletin of the Aust. I. M. M.

raiced to permit the solution to flow from the first to the second, and so on, finally reaching the storage-vat for acid-wash liquors. In these vats the pulp settles, and the clear wash-water, which contains a little copper, is either displaced by adding fresh water to No. 1 or by decanting to the acid-wash storage-vat. The thickened pulp is discharged through a bottom-discharge pipe into a large brick bin, where it is allowed to dry sufficiently to be sent to the roasting-department. All bluestone-plant residues, which represent about 40% by weight of the original high-grade matte leached, are incorporated in the H. & H. pot charge, which forms part of the ordinary daily charge to the blast-furnace. Of the metal in the high-grade matte, all the gold, silver, and lead are retained in the residue, together with 46% of the iron, 32% of the zinc, and 9.5% of the copper. The gold, silver, and lead are thus separated from 90.5% of the copper, and are subsequently recovered with the bullion produced in the blast-furnace, the copper that escaped solution being again removed by drossing.

PURIFICATION OF THE LIQUORS. Iron is the chief removable impurity; during its precipitation the whole of the arsenic and antimony are also precipitated. The Hofmann system of purification is employed. In the presence of air and copper oxide (in hot liquors) ferric sulphate is oxidized, then precipitated as ferric oxide, and a chemical equivalent of copper goes into solution as copper sulphate. A departure from the somewhat elaborate purifier, as described by Hofmann, has been made: all liquor purifications are carried out in an ordinary agitation-vat. Several methods of applying the air have been tried, but the best results have been obtained by delivering both air and steam at a point near the bottom of the agitator, either by two independent lead pipes of equal length strapped together—one for air and the other for steam—or by mixing the air and steam in one lead pipe, which is fixed securely to the inside of the agitator by means of wooden cleats.

The agitator is filled to the correct level with impure neutral leach-solution. A sample of the liquor is taken, and tested for iron in the ferrous state; the agitator is then started, and steam and air are turned on. For the necessary copper oxide either ordinary roasted high-grade matte or roasted copper precipitate is used; as the temperature rises in the agitator, about 300 lb. of roasted matte or precipitate is added. The progress of the purification is carefully controlled; a sample of the liquor is taken every hour, and a test is made for ferrous iron by acidifying the sample with sulphuric acid and titrating direct with standard potassium permanganate. In the presence of the added copper oxide (in the roasted matte or precipitate), no appreciable iron in the ferric state is found in the solution; therefore a titration for iron in the ferrous state gives a true working indication of the total iron in the solution at any stage of purification. The amount of iron in the impure neutral liquors varies considerably, according to the amount of the iron in the matte treated and the completeness of the roasting. The maximum iron found in the impure leach-liquors is about

10 grammes per litre, and the minimum about 2.0 to 2.5 grammes.

The degree of purification desired is from 0.15 to 0.2 gm. of iron per litre. From 5 to 15 hours of agitation and aeration is necessary; when the purification is finished, the agitator is stopped, steam and air are turned off, and the charge is allowed to settle. The clear solution is then decanted and sent to the storage-vat for purified liquors. The following tabulation shows the completeness of the removal of iron, arsenic, and antimony, the zinc being unaffected:

	Grammes per litre				
	Cu	Fe	As	Sb	Zn
Impure liquor	73	5.1	1.05	trace	3.0
Purified liquor	80	0.15	trace	nil	3.1

After decanting the purified liquor, the residue, which contains a considerable amount of precipitated ferric oxides, is given a weak acid wash to dissolve the unconverted copper oxide. About three hours agitation is given. The residue is allowed to settle, and the liquor is decanted to the acid-wash liquor-storage vat. If necessary two acid washes are given; then the residues are discharged, with water, in exactly the same manner as ordinary leach-residues when making up neutral impure liquors. All acid-wash water is used as subsequent leach-solutions for fresh charges of impure liquor.

CONCENTRATION OF THE PURIFIED LIQUOR. The main evaporating pan is a rectangular lead-lined wooden vat of 750-gal. capacity. The first arrangement consisted of six 4-in. lead-covered boiler tubes, let into the vat longitudinally, with a fire-box, suitable for burning coke, at one end, and a chimney at the other. The rate of evaporation proved to be too slow, and the coke consumption was abnormal. Steam-coils were then used, the first being made of 1-in. soft-lead piping. The best results have, however, been obtained by using 1½-in. antimony-lead piping, containing 4% antimony. On account of the strength of the hard-lead piping, the scale can be removed periodically without injury to the coil. An analysis of the scale that forms is as follows: Lead, nil; copper, 28.8%; iron, 0.4%; zinc, 0.9%; antimony, trace; arsenic, 0.9%; sulphur, 14.5%; and sulphur as SO₂, 14.5%.

The evaporator will not hold enough concentrated liquor to fill a crystallizing-vat, therefore when the liquor in the evaporator has attained a specific gravity of 1.4 it is sent to a storage-vat provided with a lead coil, using the waste steam from the evaporator. This storage-vat acts as a concentrator, and also as a means for thoroughly clarifying the liquor before it gravitates to the crystallizers, where it is delivered at a specific gravity of from 1.42 to 1.43, and at a temperature of from 80° to 85°C.

CRYSTALLIZERS. The crystallizing-vats are made of brick; they are lined on the sides with 8-lb. sheet-lead, and on the bottoms with 10-lb. sheet-lead. The vats are 8 ft. by 10 ft., by 2 ft. 9 in. high. To give the maximum surface on which the bluestone crystals can be built, each vat has 112 sheet-lead strips, 8 in. wide and 4 ft. 3 in. long, hung on 4 by 2-in. hardwood battens, and allowed to extend down to within about 7 in. of the bottom. When

it is desired to fill a crystallizer, all the strips are placed in position; the hot concentrated liquor is then gravitated from the storage vat; the surface is protected with a hessian cover, and it is allowed to cool slowly. From 2 to 2.5 tons of dried bluestone is made per charge.

When the crystallizer is to be emptied, the mother liquor is removed by means of a steam-ejector. The crystals are knocked off the strips and sides, then shoveled out and delivered to the washer.

TREATMENT OF THE MOTHER LIQUOR. An average analysis of the mother liquor in grammes per litre is as follows: Copper, 84; iron, 0.8 to 2; zinc, 11; and free sulphuric acid, 1.8. Its specific gravity is 1.26. The original procedure was to concentrate further the mother liquor, and to produce a second crop of bluestone, but it was found that the resulting crystals were of low grade, which necessitated re-dissolution and re-crystallization. The bluestone contains: copper, 24.95%; copper sulphate, 97.5%; iron, 0.065%; and zinc, 0.15%.

As only a first-class grade of bluestone is being boxed for sale, the necessity of re-dissolving the low-grade bluestone reduced the capacity of the plant to such an extent that some other means of dealing with this product had to be devised. The present practice, which overcomes the production of any low-grade bluestone, is to by-pass and run over scrap-iron a definite quantity of mother liquor each week, returning the remainder to the purified-liquor storage-vat. The result is that no accumulation of zinc (which is the chief impurity) takes place, and only high-grade bluestone is produced.

The copper precipitate from the mother liquor, which is by-passed, represents about 15% of the copper leached from the matte. It is roasted, and returned to the purifier as a source of copper oxide. The only bluestone now being re-dissolved is the undersize from the hutch of the washer. This is dissolved in mother liquor in an agitator provided with a paddle and steam-coil. The crystals are added to the liquor until a specific gravity of 1.435 is obtained. The liquor then goes to the crystallizer, together with ordinary concentrated purified liquors.

TREATMENT OF THE BLUESTONE. The bluestone, as it comes from the crystallizing-vats, has to be washed and freed from any fine crystals. This is done in a jig, with a fixed screen. Mother liquor is used as the wash-liquor. The screen has 3/32-in. holes, which allow the undersize crystals to pass through into the hutch; from there they are periodically shoveled and sent to the re-dissolver. The washed crystals are shoveled from the jig screen into a centrifugal drier, from which they are transferred, when properly dried, to a screen, giving two products, minus $\frac{1}{4}$ in. and plus $\frac{1}{4}$ in. The boxes used are made of pine, and have an inside dimension of 20 in. by 10 in. by 12 in. Each box is lined with brown paper before being filled, and holds 1 cwt. of bluestone, of either the coarse or fine grade of crystals, and is branded C or F, according to which grade of crystals it contains. An analysis of the finished article is as follows: Copper, 25.26%; copper sulphate, 99.23%; nickel, 0.002%; zinc, 0.09%; magnesia, trace; lime, trace; aluminum and iron oxide,

0.07%; arsenic, trace; antimony, trace; selenium and tellurium, trace; nitrates, nil; insoluble, 0.02%. It will be noticed that, although about 15% of the copper leached from the high-grade matte is by-passed and precipitated on scrap-iron, the precipitated copper is roasted and returned to the purifier; therefore, by the method above described, a metal, which is considered as an impurity in lead smelting, is separated from the gold, silver, and lead, and converted into a profitable by-product.

Oil-Shale Exploitation

In the summary of a report on the oil-shale industry, recently issued by the Bureau of Mines, it is pointed out that:

1. Many American shale deposits are richer in recoverable oil than Scotch shales now being worked, and probably nearly equal in nitrogen content, which is a measure of recoverable ammonia.

2. Market conditions for shale products are less favorable in this country than in Scotland.

3. Great quantities of American shales are of greater thickness, and are better suited for mining than Scotch shales.

4. As yet no process for obtaining oil from oil-shale has been used in actual commercial practice in this country.

5. Indications are that the United States cannot continue long to depend on domestic petroleum production to supply completely the demand for petroleum products; and that, sooner or later, oil-shales will have to be used to help supply the deficit.

6. The shale-oil industry cannot hope to supplant the petroleum industry in a large way for many years, but will probably grow up from local industries in favorable places.

7. Costs of oil-shale operations cannot be reliably estimated until commercial practice in this country furnishes the necessary basic data.

8. The quantity, quality, and value of products and by-products to be obtained from oil-shale in this country are not known with any degree of certainty.

9. The oil-shale industry is a large-scale, low-grade, manufacturing enterprise, requiring large capital, high technical and business ability, and probably making slow return on the investment. Once economic conditions become favorable for the development of the industry and satisfactory mining, retorting, and refining processes are worked out and markets established, there should be only ordinary business risk connected with the industry.

CONSIDERABLE railroad construction and development in the Belgian Congo is planned for the near future, states a consular report. The road from Matadi to Leopoldville is to be reconstructed at a cost of 10,000,000 francs. The Katanga railway is to be extended at a cost of 30,000,000 fr.; 20,000,000 fr. is to be expended on the construction of the first Belgian portion of the Benguella railway. About 25,000,000 fr. will be spent for railway material for the Great Lakes railway.

Ventilation in Metal Mines

By D. Harrington

*Those in control of metal mines have paid little attention to the question of air circulation until forced to do so, although the subject is as important as is the case with coal mines. The coal-mine engineer must remove a dangerous gas, methane, the fumes from explosives, and other gases such as carbon dioxide or nitrogen; in metal mines there is even greater necessity. In addition, air currents are needed to reduce humidity, and temperature, and to remove the fine particles of rock dust that float in the air and are largely responsible for miners' consumption. Coal miners live to a ripe old age; many metal miners contract disease and either die early in life or are incapacitated in middle age; this is due almost wholly to the superior working conditions in coal mines, chiefly because of efficient ventilation.

The worker in a metal mine frequently works under conditions analagous, as regards heat and humidity, to those found in some of our large cities. In addition, he frequently has to breathe air that is laden with fine dust and poisonous gas. He may have to pause several times daily to wring perspiration from the few pieces of clothing he wears, and even to pour perspiration from his shoes. The atmosphere near a working face is often similar to that which would be produced in a sleeping room in which all the windows were closed tightly, and where ventilation was only possible through an open door connecting with the hall-way. The sleepers would suffer from headache; the miner's discomfort is aggravated by the presence of dust, by gases from the explosives and from decaying timber, and possibly from the high temperature and the high humidity of the surrounding atmosphere. These conditions will be alleviated only to a slight extent by the release of compressed air.

MINE INVESTIGATIONS. The following data have been obtained during observation in over 50 mines in 10 States during the past five years, supplemented by observations during the past 20 years in over 150 coal mines in 15 States, and in over 100 metal mines in 14 States. In addition, I have had access to reports by other investigators. In one large metal mine the workings extended almost from the surface to below the 3000-ft. level. Data were obtained at 158 working places, of which 87½% were below the 2000-ft. level, and 35% were below the 2500-ft. level; about 75% of the observations were made at actual working places. It was found that the average wet-bulb temperature of 158 places was 76.8°F. and the average humidity was 91.3%. There was sufficient movement of air to be detected by ordinary observation in 42 out of 158 places; in an additional 29 places the movement could be detected only by a slight inclination of a candle flame;

in 87 places (or in over 55%) there was no detectable movement of the air. Wet-bulb temperatures were as follows: 40 places, under 70°F.; 45 places, from 70° to 80°; in 61 places, from 80° to 85°; in 12 places, over 85°F. Humidities were as follows: in 22 places, under 85%; in 12 places, 85 to 90%; in 51 places, 90 to 95%; in 73 places, over 95%.

In the places with the high wet-bulb temperature and high humidity, where there was little or no movement of the air, men were doing the hardest and most important work, that is, at the working face—in drilling, mucking, shoveling, or timbering. A comfort rating was given to each place, the result being compiled as follows: 78 places, with an average wet-bulb temperature of 72.1°F. and humidity of 88.2%, were rated as 'comfortable'; 80 places, with average wet-bulb temperature of 81.4°F. and humidity of 94.2%, were said to be 'uncomfortable'. Out of 85 places with a wet-bulb temperature less than 80°F., 73 were rated as 'comfortable', irrespective of air movement or humidity; an 'uncomfortable' rating was given to those places with a wet-bulb temperature that was less than 75°F. only if excessive dust or gas were present, or if the dry-bulb temperature were high, say up to 100°F.; in the latter case and if the air were moving at the rate of 500 ft. per minute, or over, the place was rated as 'comfortable'. In this mine about 400 men were employed underground per shift; the total quantity of air supplied was about 60,000 cu. ft. per minute. Underground temperatures of rock and water varied from about 60°F. near the surface to 104°F. in the lowest levels.

The accompanying tabulation gives data as to ventilation in nine fairly large mines. It is noticeable that the average wet-bulb temperature of all the underground places visited lies between 70° and 80°F.; the humidity is 85%, or over. Mines 1 and 2, with an average wet-bulb temperature of 72.5°F. and 72.3°F., respectively, had but 14% and 25% of places that could be rated as 'uncomfortable', although 96% of the places in Mine No.1 and 100% of the places in Mine No. 2 had a humidity of over 85%. It is noticeable that in all mines with a wet-bulb temperature of 75°F., or over, half the places were rated as 'uncomfortable'. These two facts seem to indicate that 75°F. is the highest average wet-bulb temperature at which comfort can be expected, irrespective of humidity, movement, and, possibly, dry-bulb temperature. It is also noticeable that a humidity of 85% or over was found in more than 60% of the places visited and in 75% of the places of all mines but one. Air movement was almost or entirely lacking in over 60% of all places visited in four of the nine mines. The places with stagnant air were almost invariably the working places.

*Revised abstract of original paper, published with permission of the Director, U. S. Bureau of Mines.

CONDITIONS IN METAL MINES IN THE UNITED STATES

Mine	Number of places	Wet bulb, °F.	Humidity, %	Comfortable places, %	Uncomfortable places, %	Wet bulb over 75° F. % of places	Air humidity		Season	Climate		Average mine depth About 600 ft

*Not rated as to comfort.

The nine mines in the tabulation employ a total of about 5000 men underground during three shifts; five have extensive workings, are large producers, and are known as being well ventilated.

CONDITIONS AFFECTING METAL-MINE VENTILATION. The temperature of the air underground is affected by the temperature of the outside air, dependent on the depth and the extent of the workings, the velocities of air, and other considerations. The temperature of the mine air is affected by the temperatures of rock and water, by the quantity of air flowing, by oxidation or decay of timbers and ores, and by mine fires. It is also affected by the friction due to the velocity of flow, by the moving of ground, the firing of shots, the heat from lights used, and from the breathing of animals. Heated air from electric motors and from other machinery may also affect the temperature. The humidity of the air underground is affected to some extent by the humidity of the air on the surface, but much more by the moisture of the walls underground and by dripping water. Quantity, temperature, and velocity of air also affects the humidity; fans may be utilized to reduce the humidity of the atmosphere. Gases found underground may come from surface air, from the breathing of men and animals, from the lights used, from the firing of explosives, and from the compressed air used with machines or from blowers, from the operation of various kinds of machinery, from strata encountered, and from mine fires that are inactive or incipient. Dust is derived from dry drilling, from blasting, from shoveling, from tramming or dumping ore, and from timbering. Probably over 50% of all metal mines have silicious material in the ore, or in the containing walls. Silicious dust is the most dangerous of all dust, especially when taken into the lungs in an extremely finely divided form. Certain silicious dusts seem to be less injurious than others of the same composition. Non-silicious dust may be harmful ultimately; for example, the dusts of certain soluble-lead ores, which affect workers by skin absorption as well as by breathing.

GENERAL CONCLUSIONS. Ventilation, fire protection and protection, health, safety, and efficiency are closely interlocked. There is as much reason for providing adequate ventilation for metal mines as for coal mines. Metal mines rarely, if ever, make provision for ventilation until forced to do so by some untoward condition or occurrence; coal mines, on the other hand, universally provide for ventilation. Efficient ventilation of metal mines consists in supplying circulating air at places where men

work, so that they may exert themselves at maximum physical capacity without endangering health. Many metal mine officials are ignorant of the principles of air circulation, this being true of those technically educated as well as those without technical training. Workers in metal mines, including shift- and other bosses, must be educated to respect ventilating devices (such as doors, regulators, over-casts, brattices, fans) and to become as familiar with these devices as are coal miners; many metal miners and bosses consider ventilation a useless fad, and obstruct rather than aid improvements. Ventilation should be under adequate supervision; the person in charge should report to a high official; many local officials in metal mines are not in sympathy with ventilation betterments. Each mine should be ventilated within itself; interventilation of mines is likely to be dangerous, inefficient, and unsatisfactory. Every mine (coal or metal) should have a mechanically-driven fan, on the surface, in a fireproof house, that is capable of reversing the air currents without delay. Metal mines should be ventilated by fans in order to avoid danger from explosive fumes, and to provide fresh air for the workers. When the temperature of the surface air and that of the underground rock and water are about equal, in mines relying on natural ventilation the circulation of air may become sluggish or may reverse in direction. In time of a fire, naturally-ventilated mines are at a disadvantage, because of inability to control the direction of the air currents. There are records of naturally and inadequately ventilated mines which have filled with carbon dioxide or other gas. Some of the workers have been overcome, and work has been suspended. With efficient mechanical ventilation this trouble was avoided.

Workers in metal mines are much less healthy than workers in coal mines, because of the superior ventilation of the collieries. Miners' consumption is caused primarily by breathing fine particles of certain mineral dusts, especially silicious dust. Over 50% of our metal-producing mines are working in silicious material. It has been proved that the fine dust in metal mines remains suspended in still air for several hours; it causes miners' consumption, poisoning, and bronchitis; it is the cause of more deaths among our 175,000 metal miners than coal dust is among our 700,000 coal miners. Miners' consumption is caused chiefly by silicious dust. Investigations in our metal mines indicate that the air of mines so far studied is from 7 to over 40 times as dusty as in South African gold mines.

Intake air in metal mines is frequently dusty. A crusher-house may be near the collar of the shaft or of the air-intake shaft. The dustiest and most dangerous occupation underground is dry drilling, and the average dust content of air in five large mines in various parts of the United States was 205 milligrammes per cubic metre. For similar work in South African mines, but using precautions against dust formation, the air contains less than 5 mg. of dust per cubic metre. Regulations in several States are provided to prevent dust in drilling, but they are not observed. Miners appreciate the dangers from dust, but they often prefer to take the risk rather than to endure slight discomfort or extra trouble. Mine and State officials feel that, unless the miner will willingly aid, they cannot force him to protect his health and, incidentally, that of his family. It is my opinion that dry drills be supplanted by those that are equipped to prevent dust, and that the use of such devices should be enforced both upon miners and operators in metal mines. There is no valid excuse for dry drilling except in a few instances; spraying may be effective if used intelligently; on the other hand, it may intensify the dustiness of the air if used without intelligence. Efficient water-drills are now available, including efficient wet stopers for upper holes; dry drilling should be prohibited. Some dusty metal mines have comparatively little dust in the air at certain times, and a low average dust content of all places, because of the efficiency of ventilating currents especially at the working places. These mines appear to be singularly free from miners' consumption or other diseases, yet the employees work efficiently, and the material handled is highly silicious. The use of compressed-air blowers at working-faces frequently intensifies the dustiness, by allowing high-velocity air to pass through dry, loose, finely-divided ore or other material. Dust is probably the chief cause of miners' consumption, but it is now recognized that there may be other factors of almost equal influence, such as high temperatures and humidities, harmful gases, and lack of air movement, all of which may be modified by ventilation. It appears that, with a dry-bulb temperature below 75°F., mine working places may be comparatively comfortable, irrespective of movement of air or humidity. However, the presence of impure air may produce uncomfortable or unsafe conditions; such places may be both uncomfortable and unhealthful if large quantities of finely-divided dust are present. With a dry-bulb air temperature of above 75°F., comfort and maximum working efficiency can be attained only when air is moving, this being especially true if the air has a high humidity. The exact velocity necessary is a variable, dependent upon the temperature and the humidity. Saturated atmospheres, up to nearly blood-temperature, may be made endurable, and even comfortable, by providing sufficient velocity. The still air in metal mines at about 65°F. and 90 to 100% humidity has little effect on persons at rest, but with those doing even moderate work the body temperature rose to over 100°F., the blood-pressure fell

perceptibly, and the pulse-beat rose. In still air, with temperatures of 90° to 100°F. and about 90% humidity, even when almost at rest the body-temperature rose quickly, reaching over 102°F., the blood-pressure fell rapidly, the pulse-beat increased abnormally and was sensitive to even slight exercise; perspiration was profuse; dizziness, physical weakness, mental sluggishness, and headache were common; upon attempting even light work these symptoms were greatly augmented.

Humidity, even up to the saturation point, does not appear to be harmful to health, comfort, or efficiency until the temperature is above 75°F.; if sufficient movement be supplied a high humidity is not harmful until the temperature is over 90°F. Except in blind working places the air is not particularly deficient in quality. However, the air of drifts, cross-cuts, raises, winzes, and stopes is likely to be deficient in oxygen, or high in nitrogen or carbon dioxide, and, possibly, in carbon monoxide, oxide of nitrogen, or other impurities. There are many records of asphyxiation in metal mines.

Almost all explosives used in metal mines give off small percentages of poisonous fumes; when these fumes are not removed from working places by ventilation they cause headache, nausea, and, possibly, death. The gelatin dynamites give off less dangerous gases than do the ammonium dynamites; the latter give off less than the straight nitro-glycerin dynamites. Hence the straight nitro-glycerin dynamites should not be used underground; and all places using explosives should be thoroughly ventilated after blasting and before the workers again arrive. Good ventilating currents should also be provided while the ore is being shoveled. Compressed air is not effective in removing explosive fumes. Comparatively small quantities of impurities in stagnant air causes headache, and this is particularly true when the temperature is over 80°F. However, these are not noticeable when there is perceptible movement of the air.

Frequently in blind and working faces in metal mines the air is so low in oxygen that a candle will not burn, and carbide lamps must be used; the oxygen content is below 18%. Occasionally entire mines are found in this condition, and many metal-mine managers contend that it is satisfactory. There is no question that men working in an atmosphere that will not support the combustion of a candle cannot operate efficiently; their health must suffer ultimately. Mines with cool working places are likely to be extremely dangerous unless provision be made to remove explosive fumes and fine dust by ventilating currents.

The efficiency of workers in mines in which the temperature is high (above 75°F.) are likely to decrease from 25% to 75%. Workers are likely to become sick unless moving currents of air are supplied. The outcome is hastened and intensified if fine dust be present, especially silicious dust, and if there be much blasting done, especially when men are in the mine. Many accidents in metal mines are due to deficient ventilation. The failure to remove smoke and fumes prevents the proper inspection of working places. Moreover, men are likely

to be affected by dizziness or by lack of ability to think clearly or quickly, or they may faint at an inopportune time and be killed. Men have been known to drop dead from heart failure in these hot places.

Variations in surface-air temperature and humidity change conditions little, if at all, at the faces in those mines with extensive workings, hence underground temperatures in large mines vary little, if at all. Air that flows in underground passages rapidly takes the temperature of the surrounding rocks; the rate of change is variable. The temperature of still air underground rarely varies more than a few degrees from the temperature of the surrounding rock or water. Rock-temperature generally increases with depth, the rate of increase varying from one degree or more per 100 ft. of depth in certain districts of the western part of the United States, to 0.5° F. in other regions, both of the United States and of foreign countries. In Montana, the rock-temperature in copper sulphide veins is about 108° F. at a point 3800 ft. below the surface, the rate of increase being about 1° F. per 100 ft. of depth. In a lead sulphide vein in the Coeur d'Alene, in Idaho, the rock-temperature 200 ft. below the surface was but 50° F. In a Michigan copper mine with native copper ore, the rock-temperature was about 82° F. at a point 5000 ft. below the surface. In a gold-bearing quartz vein in Arizona, the rock-temperature was 90° F. at a point 600 ft. below the surface; in a deposit in another Arizona district, the rock-temperature 600 ft. below the surface was but 70° F. The temperature of coal in place in coal mines in the United States is rarely above 70° F., and is generally much less. Recent magazine articles give the rock-temperature of the Kolar goldfield in India at 118° F. at a point 6100 ft. below the surface, and 98° F. at the 4000-ft. level of the St. John Del Rey mine, in Brazil; it is calculated that at the 800-ft. level of the City Deep mine in South Africa the rock-temperature will be about 97° F. Rock-temperatures may vary at the same depth in different kinds of material; a copper sulphide ore with quartz gangue may have a rock-temperature several degrees higher than a zinc-sulphide ore in a quartz gangue in a parallel vein about 200 ft. distant.

Water standing still or flowing in mines readily communicates its temperature to the surrounding air. Water dripping through the air quickly brings the air to the temperature of the water, which is generally the same as that of the surrounding rock. Mining engineers take advantage of the use of water-sprays to cool the air, but managers fear that water-sprays will cause excessive humidity, forgetting that mines generally have the humidity anyway, and that if the air can be cooled to 75° F. or below, and given a slight movement, the high humidity is not harmful. Recent experimental work in South Africa showed that men in stagnant air with a humidity of 95% and a temperature of 87° F. did more work after a fan was put in operation to move the air; high humidity is not particularly detrimental. Air passing through fans frequently has its dry-bulb temperature increased. In one instance, the air from an under-

ground fan delivering over 20,000 cu. ft. per minute had 8° F. higher temperature at delivery than at intake, these points being less than 50 ft. apart. Similarly, small canvas-pipe units, used underground for local ventilation, frequently deliver air that is several degrees higher in temperature than that of the air at the intake. Small electrically-driven fans, with galvanized-iron or canvas tubing, are being introduced into metal mines to carry air to dead-ends. The galvanized iron has the advantage of permitting the reversal of air currents—to pull smoke out after blasting, then to force air to workers; moreover, it does not decay as fast as the canvas. The canvas tubing must be used only in forcing air to the face; its advantages lie in low first cost, readiness of installation and removal, flexibility in conforming to bends or turns, and ease of repairs. Moreover, because of readiness of installation and removal, the canvas tubing can be brought close to the working face at ordinary times, and easily removed prior to blasting. Either method readily permits of placing from 500 to 1000 cu. ft. of air per minute at the working face for a comparatively small cost. Compressed air from the end of a hose is used to a great extent to ventilate working faces in metal mines; its temperature rarely varies much over two or three degrees from the temperature of the rock and air of the working face. Such a method is useless for the removal of smoke or gas, it provides comparatively little pure air, and ensures little reduction of temperature. The use of electrical machinery underground causes a considerable increase of temperature.

In the event of a fire in a metal mine, the lack of an efficient ventilation system may be disastrous. There should be a definite system of air-splits, so that fire in one place may not necessarily fill the entire mine with poisonous gas. There should be a system of doors, so that the shaft or any part of the mine may be readily isolated in case of fire. The lining of shafts with concrete will reduce friction to such an extent that additional air can be handled by the same expenditure of power. It is also found that in the case of small fans with canvas tubing, the same amount of air will be delivered with a saving of one-quarter to one-third of the power by the use of fans with one-half to two-thirds the width of the standard fans. If the lining is done by the use of 'gunite' it also serves as fire-proofing. The expense of establishing a ventilating system for a large mine varies, but the cost of operation is not particularly burdensome; it will be met by savings in compressed air, in increased efficiency, and in the improved health of employees; the savings effected may return the investment within a few years. Miners' consumption costs the mining industry in South Africa about \$6,000,000 annually; it probably costs the metal mines of the United States more than that, in addition to many lives and much misery. By systematic work in dust prevention and ventilation, the death-rate from such causes in South Africa has been reduced from 35 per 1000 in 1910, to 13 per 1000 in 1915, and to about 11 per 1000 in 1920, the last figure including the casualties from influenza.

Book Reviews

The Fruits of Victory. By Norman Angell. 338 pp. Published by the Century Co., New York. Price, \$3.

This is a sequel to 'The Great Illusion', which appeared in 1911. Mr. Angell's earlier book was widely read and made men think; it reached the heads of governments, but they disregarded his argument and unwittingly proceeded three years later to prove his main thesis—that war is an economic futility, even to the victor. In 1914, on the eve of the Great War, a friend greeted me one morning with the question: "What do you think now about 'The Great Illusion'?" He was one of many who thought that Mr. Angell had expected to stop war; indeed, he thought, I believe, that the author considered the possibility of another war as the illusion. Mr. Angell is too much of a philosopher to expect that his warning would convert an obstinate world to an immediate acceptance of his conclusions. So he returns to the charge. He might say now, pardonably, "I told you so. You have had an Armageddon, a war on a tremendous scale, between the principal nations; each of you expected results beneficial to yourselves; you even introduced sundry fine sentiments to glorify the horror of carnage and destruction; but what have you gained? What are the fruits of victory? The fruit is a Dead Sea apple, fair outside but turning to ashes when plucked". So Mr. Angell ventures again to preach disillusionment to a world that, he is warranted in hoping, is sadder and wiser—perhaps also in a better mood to heed him.

An unsigned introduction to the American edition of the book sets out to emphasize the importance of the subject to the American public. This may seem supererogatory, but I think not, for our people have felt the argument of experience much less than the Europeans and are hardly aware yet how much their own welfare is bound up with that of their neighbors—for neighbors all we are. That is one of the author's main arguments: the economic interdependence of the peoples of the earth. The "splendid isolation" that was the keynote of Great Britain's policy toward the continent of Europe was defended by reasoning similar to that now put forth by American publicists. We ought to realize that the aeroplane, the submarine, wireless telegraphy, and the innumerable ties of international commerce have ended any attempt to live alone, in economic and political detachment. Great Britain failed to preserve her isolation. We shall fail likewise. "Indeed", says the writer of the introduction, "Great Britain found that at no period of her history were her domestic politics so much dominated by the foreign situation as when she was proclaiming to the world her splendid isolation from foreign entanglements. It is as certain, of course, that American 'isolation' would mean that the taxation of Gopher Prairie would be settled in Tokio; and that tens of thousands of American youth would be sentenced to death by unknown elderly gentlemen in a European cabinet meeting."

The author writes his book in the form of summaries and accretions, detrimental to its literary quality but helpful to his purpose of convincing the reader. First comes a 'Summary of the Argument'. "Underlying the disruptive process", he says, "is the deep-rooted instinct to the assertion of domination, preponderant power. This impulse, sanctioned and strengthened by prevailing traditions of mystic patriotism, has been unguided and unchecked by any adequate realization either of its anti-social quality, the destructiveness inseparable from its operation, or its ineffectiveness to ends indispensable to civilization." In short, war is the result of a tradition that ignores the structure of civilized society, and is destructive of it. Next comes a 'Synopsis' of the seven chapters. He argues that the interdependence of peoples is such that to fight is suicidal, that

war is the supreme futility, that the victor suffers no less than the vanquished, and that the victor has to assist the vanquished for his own self-interest in order to prevent a break-down in the machinery of civilization and the disintegration of social life. "The victor on the Egyptian vase has his captured enemy on the end of a rope. We say that one is free; the other bond. But as Spencer has shown us, both are bond. The victor is tied to the vanquished; if he should let go the prisoner would escape. The victor spends his time seeing that the prisoner does not escape; the prisoner, his time and energy trying to escape. The combined efforts in consequence are not turned to the production of wealth; they are 'cancelled out' by being turned one against another. Both may come near starvation on that condition if much labor is needed to produce food. Only if they strike a bargain and co-operate will they be in the position each to turn his energy to the best economic account." Consider the relations of France and Germany today; consider our effort to resume commerce with those whom we helped to defeat three years ago. War is incompatible with the interdependence that is essential to the welfare of civilized peoples. The pugnacity that develops from patriotism breaks the ties that render possible a highly organized system of life on the earth. What price then are we willing to pay for a law that will protect this interdependence? As citizens we subdue our self-assertiveness for the sake of community life; how much of our national assertiveness are we willing to forego for the sake of the larger world life? If we do not restrain the combative instinct by self-discipline, we, as nations, shall plunge into the hellish futility of war after war.

Let me quote a few of Mr. Angell's most incisive sayings: "As interdependence increases, the limits of coercion are narrowed. Enemies that are to pay large indemnities must be permitted activity to develop their economic life and power; they are then so potentially strong that enforcement of the demands becomes correspondingly expensive and uncertain". "If to nationalist hostilities as we have known them in the past is to be added the commercial rivalry of nations now converted into traders and capitalists [he has laid stress on the growth of State Socialism as introduced for the purpose of conducting warfare], we are likely to have not a less but a more quarrelsome world, unless the fact of interdependence is much more vividly realized than in the past." He asks if we have the right to deny to others the means of life. "This 'right' to starve foreigners can only be invoked by invoking the conception of nationalism—'our nation first'. But the policy of placing life itself upon a foundation of preponderant force, instead of mutually advantageous co-operation, compels statesmen perpetually to betray the principle of nationality; not only directly (as in the case of the annexation of territory, economically necessary, but containing people of alien nationality), but indirectly; for the resistance which our policy (of denying means of subsistence to others) provokes, makes preponderance of power the condition of survival." He speaks from the Irish standpoint; the United States was not in the War as soon or as deeply as the others and did not feel compelled to shut off food from the enemy; indeed we fed our enemies immediately warfare ceased; but if we were in a war to the death, to preserve our national life, we also would not scruple to starve the enemy. "The greatest and most obvious need of Europe, for the salvation of civilization, is unity and co-operation. Yet the predominant forces of its politics push to conflict and disunity. If it is the calculating selfishness of 'realist' statesmen that thus produces impoverishment and bankruptcy, the calculation would seem to be defective." "In war-time, pugnacity, partisanship, coerciveness can find full satisfaction in the fight against the enemy. But when the war is over, these instincts, which have become so highly developed, still seek satisfaction. They may find it in two ways: in conflict be-

tween Allies, or in strife between groups within the nation. We may here find an explanation of what seems otherwise a moral enigma: that just after a war, universally lauded as a means of national unity, 'bringing all classes together', the country is distraught by bitter social chaos, amounting to revolutionary menace; and that after the war which was to wipe out at last all the old differences which divided the Allies, their relations are worse than before the War (as in the case of Britain and France). "Instinct, being co-terminous with all animal life, is a motive of conduct immeasurably older and more deeply rooted than reasoning based on experience. So long as the instinctive, 'natural' action succeeds, or appears to succeed in its object, we do not trouble to examine the results of instinct or to reason. Only failure causes us to do that." The failure of the combative instinct provokes the inquiry to which the book is an answer. We ought to profit from experience in our relations as individuals. "We try other methods when we really discover that force won't work. When we find we cannot coerce a man but still need his service, we offer him inducements, bargain with him, enter a contract. This is the result of realizing that we really need him, and cannot compel him." "Faith in the social method is the condition of its success. It is a choice of risks. We distrust and arm. Others, then, are entitled also to distrust; their arming is justification for distrusting them. The policy of suspicion justifies itself. To allay suspicion we must accept the risk of trust. That, too, will justify itself." "If our instinctive pugnacities and hates are uncontrollable, and they dictate conduct, no more is to be said. We are helpless victims of outside forces, and may as well surrender." We do not intend to surrender. Man is a thinking animal, and by reason of his power of thought he has curbed some of the bestial instincts that he inherited from his early days in the jungle; it remains for him to curb others that are inconsistent with civilization.

The argument of the book is so closely knit that it is difficult to summarize. It should be read by every thoughtful man, especially in view of the forthcoming conference at Washington. Mr. Angell is not a discredited prophet, as some would have us believe; on the contrary, he has 'made good': he did not say war was impossible, he said it was futile; he insisted that war on a large scale would become civil war and that civil war would be suicidal to humanity. He is justified by the event.—T. A. R.

Induction Motor, and Other Alternating-Current Motors. By B. A. Behrend. Second edition. 272 pp., ill., 6 by 9. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$4.

The author explains that this is not a work of an encyclopedic character. It is essentially the work of an engineer who has had the good fortune to have been actively associated with the art of electrical engineering through almost three decades, and who has had a part in the development of the machines about which he writes. He reveals the methods that he has followed in design and construction of alternating-current motors. The design of electrical machinery, as of all machinery, we read, is based upon intelligent comparison of empirical data; and the art of designing cannot be taught without such data. The methods and principles enunciated in this book aim solely at assisting the student of effecting such comparisons. To 'calculate' a machine, as the term is frequently employed, is not feasible, and only principles and fundamentals can be taught in school. The author makes no apology for the number of personal references that occur. He points out that the tendency to write books without references is due largely to the desire on the part of the author to avoid consulting the papers of other writers. The reader is not benefited by

such treatment, as he may frequently prefer the original paper to the abstract quoted by the author of the book he is reading. Besides, states Dr. Behrend, a knowledge of the literature of the profession is essential to understanding the art and to an honest interpretation of the part played therein by our fellow-workers. The contents of the book are as follows: I. Introduction. II. Theory of fluxes and stray fields. III. Alternating-current transformers. IV. McAllister transformations. V. Rotating field and the induction motor. VI. Induction generator. VII. Short-circuit current and the leakage-factor. VIII. Double squirrel-cage induction motor. IX. Polyphase commutator motors. X. Series polyphase commutator motor. XI. Shunt polyphase A. C. commutator motor. XII and XIII. Methods of speed control. XIV. Types of variable-speed polyphase commutator motors. XV. Methods of raising the power-factors of induction motors. XVI. Magnetic pull with displaced rotor. XVII and XVIII. Single-phase induction motor. XIX. Single-phase repulsion motor. XX. Single-phase commutator motors. Appendix.

Chemical and Metallographic Examination of Iron, Steel, and Brass. By W. T. Hall and R. S. Williams. 501 pp., 5½ by 8½, ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$5.

This book, written by the translators of Bauer and Deiss' 'Sampling and Analysis of Iron and Steel', covers not only the chemical analysis of alloys but the examination of polished specimens. It is shown that the necessity for the chemical analysis of alloys has long been recognized, but modern methods of manufacture and the use of metals under conditions of severe strain demand additional information which can best be obtained by the examination of polished specimens. Part I deals with the chemical analysis of alloys, and includes well-tested methods of analysis, selected mainly from reports of the U. S. Bureau of Standards, or from papers of the American Society of Testing Materials. Although most of the standard methods of steel analysis are included, special emphasis has been placed on those methods that are rapid and accurate. Part II considers the physical rather than the chemical inspection of metals, and describes the methods of preparation and examination of polished metal surfaces as an independent means of determining the quality of material, as well as an aid in getting representative samples for chemical analysis. A brief introduction to metallography, in so far as it applies to the inspection of alloys, is included. A portion of the translation of 'Sampling and Analysis of Iron and Steel' is included in the book, notably several tables and a number of photo-micrographs.

American Electricians Handbook. By T. Croft. 823 pp., pocket size, ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$4.

This is the second edition of a useful little book that was first published in 1913. In compiling it, the aim was to collect such information as would enable practical electricians to select and install commercial electrical apparatus and material, and to qualify them to operate the equipment after it had been installed. Theoretical discussions have been included only where they may be of assistance to enable the reader to understand why he should do certain things in certain ways. Although prepared primarily for the use of men with little schooling, it is designed to give practical information on materials, and suggestions for the selection, installation, and operation of equipment, that will be of service to the technically trained engineer. The volume, as now revised, comprises six divisions: Fundamentals, Generators and Motors, Outside Distribution, Interior Wiring, Transformers, and Electric Lighting. It will be found useful to the mining engineer, as well as reliable.

REVIEW OF MINING

DEVELOPMENT OF FLIN FLON MINE INDICATES 25 MILLION TONS OF COPPER ORE

On the Flin Flon copper property, east of The Pas, in Manitoba, controlled by the Mining Corporation of Canada, development shows that the orebody occurs in lenticular form being 300 ft. in width at its widest point and tapering at the ends. A total of 43 diamond-drill holes have been put in and the deposit has in that way been explored to a depth of 1000 ft. In addition two shafts have been put down, one to a depth of 200 and the other 300 ft., and cross-cuts have been driven at the bottom of each shaft. The development proves that the ore is of higher grade than was indicated in the diamond-drill cores. The average content, valuing copper at 13c. per pound, is approximately \$7 per ton. The total proved, probable, and possible ore now indicated is estimated at 25,000,000 tons. The property is now idle, but with conditions moving steadily toward normal, it is not likely that active development will be long delayed.

MINING IS ACTIVE IN BEAVER COUNTY, UTAH

J. C. Brumblay, ore-purchasing agent for the United States Smelting Co., has been making a tour of mining properties in Beaver county in Utah. Mr. Brumblay reports that twice as many men are employed in the mines at present as there were a year ago. At the Humboldt mine, silver-lead shipping ore was recently opened on the 100-ft. level. This ore will average from 20 to 25% lead and carries considerable silver. Three streaks of high-grade ore are being followed in the Red Warrior mine, while a face of high-grade shipping ore is being worked in the Moscow property. After being closed for six months, the Wild Bill mine is being worked by lessees. Two shoots of ore are being mined, averaging from 20 to 25% lead and 7 to 8 oz. silver. The most promising property is the Gold Crown. An orebody in this mine has been followed for a distance of 500 ft. The ore is richer in lead and silver than any found in other properties in the district; the vein is from 2 to 5 ft. thick.

CERRO DE PASCO COMPANY PRODUCED 4,594,000 LB. OF COPPER IN SEPTEMBER

The Cerro de Pasco Copper Co. is one of the few big producers that is 'breaking even' on operations. The company's copper ore has a high silver content; silver sold at 73½c. per ounce recently and this helps the Cerro de Pasco company materially.

In the first months of this year output totaled 39,810,000 lb. If the company keeps on turning out 4,594,000 lb. per month as it did in September copper production this year will total more than 53,000,000 lb. Output in 1920 was 52,790,000 lb. The high record year was 1917 when 72,674,032 lb. was produced. The company does not publish its silver or gold output. The metal is refined and sold by the American Metal Co., hence the company did not supply any of the 400,000,000 lb. of copper which was set aside and held for re-sale abroad by the Copper Export Association. To carry its own metal, Cerro issued \$8,000,000 ten-year 8% bonds, convertible into stock at the rate of 30 shares for

each \$1000 bond. This financing put the company in a position where it was fully able to carry its own metal. It is estimated that the company produced about 6,000,000 oz. silver last year, and ought to turn out an equal amount this year, if copper production keeps on at the present rate. Due to the high gold and silver content of the ore, coupled with cheap Peruvian labor, Cerro ordinarily is one of the lowest-cost copper producers in the world.

PLANS OF THE COPPER AND BRASS RESEARCH ASSOCIATION

According to William A. Willis, general manager for the Copper and Brass Research Association, who just concluded a visit through the Lake Superior copper region, the copper and brass industries are not looking to the Government to rehabilitate them. They are prepared, he stated, to "fight their own fight" and believe public education and research are the best weapons. "It has been made clear to the copper and brass interests that not enough people understand the exclusive advantages of these metals," he declared. "Therefore a campaign of education has been undertaken, which, with the necessary research work, is being directed by the association. Copper and brass represent a higher initial cost than many other metals and materials that are sometimes used in their places, but the life of copper and copper products is everlasting, their service is uniform, they involve no upkeep expense, and, because of these things, they represent a substantial saving to the user in the long run. This is the message that copper and brass has for the American public." Mr. Willis likened copper's experience to that of the veteran who went to war and when he returned found somebody else in his place. Every pound of copper that could be mined and refined in this country was needed for war purposes, and when the conflict was over copper and brass came back to find that their places in many uses were being filled by substitutes.

AMERICAN MINING CONGRESS CONCLUDES ITS SESSIONS

The annual convention of the American Mining Congress held at Chicago was concluded on October 22, after five days of sectional conferences and general sessions. Twenty resolutions were adopted dealing with sundry phases of the industry. W. J. Loring was re-elected president for the ensuing year.

EXPORT OF OIL FROM MEXICO DURING SEPTEMBER

Exports of oil from Mexico in September were 17,637,179 bbl., one of the biggest month's shipments thus far. They compared with 5,528,000 in August and 6,215,000 in July, these two months being, of course, during the shut-down period. The record month thus far was January of this year, when 18,480,000 bbl. was exported.

Standard Oil Co. of New Jersey leads with shipments of 3,254,005 bbl. under its own name. To this should be added 1,103,750 bbl. exported under the name of International Petroleum of Maine, which was oil bought by Standard under its contract with International. This made 4,357,755 bbl. for Standard Oil for the month, or more than 25% of

the total. Mexican Petroleum Co. stood second with exports of 3,179,163 bbl. for the month, consisting of 55 tanker loads, probably the largest number of tankers loaded by any company in Mexico in a month.

Much of the oil moved in September came from storage, as several companies show shipments for September which may be considered abnormal in view of the fact that much of their production has been destroyed by salt water in August and September. This, particularly, refers to those which had sizeable production in Amatlan and are not producers in Toteco and Cerro Azul. It is from these two districts that the biggest part of Mexican light oil must come in future. For this reason the normal export of oil from Mexico may be said not to be more than 12,000,000 bbl. per month, after stored oil has been shipped.

Other exporters in September were Mexican Gulf Oil, 1,183,294 bbl.; Freeport-Texas, 361,649; Island Oil, 1,263,885; Atlantic Gulf & West Indies, 1,196,907; United States Mexican, 148,557; Texas Co., 986,491; New England Fuel Oil, 159,439; Continental Mexico, 212,520; National, 138,018; Cortez (Atlantic Refining), 427,669; Corona, 984,234; Inter-ocean, 51,412; National Oil, 51,640; East Coast, 365,644; and Mexican Eagle, 1,568,900.

MINING ACTIVITY AT TONOPAH GREATER THAN FOR FIVE YEARS

With the Belmont, Tonopah Extension, Tonopah Mining, and West End companies operating with full crews, and the North Star, Rescue-Enla, New California, Jim Butler, Mentana, and other properties yielding substantial quantities of good ore, the output of Tonopah district is the heaviest in five years. The Belmont, Extension, West End, Tonopah Mining, and MacNamara mills are running at capacity, with the Belmont plant at Millers also treating a good tonnage. Conditions at Divide are slowly improving, the result of recent ore developments in the Tonopah Divide and Gold Zone mines. Tonopah Divide is centering work on sinking of the shaft to the permanent water-level, development of the new gold lode on the 800-ft. level, and mining of ore on the main levels for shipment to the Belmont mill.

ALASKA

Hyder.—The towers of the Premier tramway are completed, and the work of stringing the cables has been started. It is thought that the tramway will be in operation before the end of November. There is to be a sale of a large number of Crown-granted claims on November 8 for delinquent taxes; among these are 50 claims on Queen Charlotte Islands, belonging to the Ikeda Mines, Ltd.—The Portland Canal Mines, Ltd., has started exploration work at the Big Missouri; 20 men are employed under Pat Daly and will continue explorations during the winter.—Pat Daly has bonded the New Alaska group, on the Alaskan side of the International boundary.—John Hoar and associates are opening up a gold property at Kellum lake, near Terrace, and are erecting a Ross mill.

ARIZONA

Bisbee.—W. H. Webster, assistant manager for the Copper Queen branch of the Phelps Dodge Corporation, has announced that steam-shovel stripping on Sacramento hill will be suspended on October 30. This will affect 150 men, but further work cannot be done economically until shipment of ore has commenced. Steam-shovel work on Sacramento hill was started more than four years ago. Since then 5,500,000 cu. yd. of material has been removed. The continuing of this work during the last few months furnished employment for many, and aided greatly in tiding Bisbee over the period of curtailment of activity. During

the last few months a stock-pile of over 175,000 tons of concentrating ore has accumulated and about 375,000 tons of lower-grade ore has been placed on the leaching-dump site south of the new mill.

Kingman.—A cross-cut has been started in the east drift on the 100-ft. level at a point 250 ft. from the shaft of the Gold Chain mine. The cross-cut at 125 ft. from the shaft revealed a vein 16 ft. wide, the ore assaying approximately \$16 gold per ton, according to reports.—A 25-hp. hoist and a No. 5 Cameron sinking-pump are now operating on the 400-ft. level of the Katherine mine. The purpose is to expedite the sinking of the winze near the face of the east drift on the 400-ft. level. According to reports, grab-samples from the winze at a point 22 ft. deep returned as much as \$32 per ton.—Shaft-sinking has been resumed at the Revenue property. It is expected to sink to the 400-ft. level before cross-cutting is undertaken. New buildings, a hoist, and a compressor have lately been added to the plant.

CALIFORNIA

Bridgeport.—The Success Mining Co. has exposed a 3½-ft. vein of high-grade ore in its property in the Masonic district. The find was made in a drift north from the 50-ft. level. The Success mine was purchased by Elmer S. Green and associates from John H. and C. C. Hayes, of Bridgeport, in July.

French Gulch.—The deed transferring the Great American Copper mine from D. J. Williamson to Albert Hanford has just been recorded. The consideration is \$10,000. The property adjoins the Greenhorn group, which was purchased by Hanford a few months ago.

Grass Valley.—The North Star company has increased its force by 100 miners during the last three months; there are now 460 men on the payroll.

Jackson.—The new compressor and motor for the Moore mine have been delivered. This equipment has considerably larger capacity than that in the present plant. Unwatering will commence as soon as the machinery is installed.

Oroville.—At the Gold Mary mine, near Gravel Range, 400 tons of rich quartz ore has been blocked-out. Work will be suspended during the winter, but a 3-stamp mill will be operated next spring.

Spanish Dry Diggings.—The clean-up at the Grit mine for September is reported as being \$9000. A payment of \$7500, due W. A. Buckman on the purchase price of the property, was made on October 18. The final payment of \$20,000 is due on November 1, 1922.

Weaverville.—Preparations are being made by Grover and William Lorenz for operation during the winter. The Lorenz mine is the most important hydraulic mine in Trinity county.—W. R. Bigelow is building a new flume to the Enterprise mine near Helena. Mining will be resumed as soon as the rains commence.

COLORADO

Creede.—A new producer for the Sunnyside section is the Corsair, where lessees have opened up a strong body of silicious ore with good silver content. Shipments will commence soon.—A cyanide plant for the treatment of low-grade ores of the Monte Carlo group, will be erected if sampling now in progress is satisfactory.—The First National Mining Co., owning the Mollie S. group, has been re-organized as the Mid-West Mining Company.

Cripple Creek.—Connection through to the 20th level station has been made at the Vindicator No. 2, or main shaft, and timbering is in progress. Increased production from the rich Little ore-shoot, opened up while cross-cutting under the Vindicator shaft from the 1800-ft. level of the Golden

Cycle, will follow.—Diamond-drill prospecting has commenced at the Mary Ann, adjoining the Cresson, on Raven hill. The property is under lease to the Bull Haven Mining & Development Co., recently incorporated, also operating the Maude Helenas on Bull hill. A third shift has been put to work at the Independence mill of the Portland Gold Mining Co., and the plant is now operating at capacity on low-grade ores; company and custom ores are treated.

Lessees on the Gold King in Poverty gulch are maintaining steady production.—A rich pocket recently was opened by lessees at the 11th level of the Mary McKinney mine; a recent shipment settled for \$5 per pound.

Florence.—The smelter of the River Smelting & Refining Co. is scheduled to resume treatment with a full operating force by the middle of November, according to H. H. Utler, general manager. The River smelter closed down last spring when about 200 men were laid off. The resumption of treatment will be of benefit to the Leadville district.

Hot Sulphur Springs.—The Electro Copper Co., whose property lies on the boundary between Eagle and Routt counties, has developed a large deposit of copper ore that is estimated to average 4%; 1850 ft. of drilling and cross-cutting has been done from the main adit. The property is well equipped. William R. Rathbun is general manager.

Ouray.—Operations have been resumed by the Lucky Twenty Mining Co. on the Guadalupe. A tunnel is projected to exploit the ground 500 ft. below the present deepest workings. The property is under lease to the operating company.

Silverton.—Capitalists from Pittsburgh, Pa., have become interested in the Klittimac gold mines, Minnie gulch; development work on both north and south veins is in progress.—An orebody has been opened in the Gladstone tunnel, south of Silverton, 4 ft. wide, with ore shipping 20% lead and 38 oz. silver per ton. A mill-run on 800 tons resulted in 100 tons of concentrate assaying 30 oz. silver, 24% lead, and 0.50 oz. gold per ton.

IDAHO

Coeur d'Alene.—A carload of ore is ready to ship from the Western Union mine. This is the first carload loaded by Kroan and Johnson since they secured a new lease. They have opened the orebody at a point 100 ft. east of where they were working, and the new opening is said to show ore carrying 80% lead and 40 oz. silver. The last carload shipped by these men under the old lease netted \$2511.—Almost nine feet of clean lead-silver ore has been cross-cut on the Puritan level and on the level 200 ft. deeper in the Tamarack & Custer mines.—Work has been commenced on a one-mile tunnel to be run into the Ajax Mining Co.'s property at Burke, to secure additional depth of 550 ft. below the bottom of the present workings. Ajax ground has been worked through the Moonlight tunnel, for which the Ajax had a 10-year lease.

Three mining companies are concerned in the new development program of the Silver Reef Mining Co. In order to reach lower levels in its own property the Silver Reef has entered into a contract with the National Copper Mining Co. to use the lower tunnel of the Homestake Mining Co. The National controls the Homestake. By this arrangement the Silver Reef will develop its own ground and that of the Homestake and the National will be benefited by explorations in Homestake ground. The properties are near Mullan. The Homestake and Silver Reef have the same vein. The Homestake tunnel is in 400 ft. following the vein and must be extended 800 ft. to reach Silver Reef ground. Work under the new contract will be started at once by the Silver Reef company.

Talache.—The Armstead Mines will place its mill in operation on January 1 next, according to present plans. The

building is almost completed and machinery for its equipment is arriving daily. Work in the mine is being pushed. The three-compartment raise has reached the 400-ft. level, giving it a height of 800 ft. or more above the main-tunnel level. The mine will be in a condition to deliver 150 tons of ore daily by the time the mill is ready to receive it. The average grade of this ore is 22 oz. silver per ton.

MICHIGAN

Houghton.—The Mohawk Mining Co. has brought suit for \$125,000 for the use of the 14 miles of railroad between its mine and mill during the period of Federal railroad control and operation of the Copper Range railroad from June 25, 1918, to March 1, 1920. It holds this to be a fair and reasonable rental of its railroad facilities, having paid for hauling ore during that period upward of \$350,000.

In connection with the discussion of the wearing qualities of copper for roofing, it is of interest to note that the Houghton county court-house, built in 1886, has a copper roof which has required no repairs and is as good as the

South-Western Part of Colorado

day it was put on; the tower of the town- and fire-hall of Houghton was covered with copper in 1883 and no repairs have been necessary to date, a period of 38 years.

The Michigan smelter, which treats Copper Range, Mohawk, and Wolverine mineral, has effected a notable economy by means of its coal-pulverizing plant. It has been in operation now for several months and is working smoothly and efficiently, the results being most gratifying. It has cut coal consumption down almost two-thirds in the furnaces. The coal is pulverized and is then automatically fed into the furnaces by means of compressed air. Whereas it formerly took 1500 lb. of coal to treat a ton of mineral it now requires only 525 lb. The plant was built at a cost of \$150,000, but will pay for itself in three years' time. A possibility exists that some day powdered peat will be used as fuel in furnaces in place of coal. There are immense peat beds only a few miles from Houghton and these are now about to be developed, and one of the first experiments will be with powdered peat as fuel.

MONTANA

Butte.—Further experiments by the Anaconda Copper Co. in the manufacture of metallic shingles, made of an alloy of copper and zinc, have resulted in increasing the size of the product to a length of six feet, it being believed that this enlarged size will appeal to constructors as a time-saver on

roofing work. The company has tried out the life of zinc sheets for roofing and while these have stood remarkably well, they are not to be compared with those made of copper, tried upon one of the converter buildings at the Washoe reduction works. By making a shingle of an alloy of the two metals it is thought the ideal material has been developed. By the addition of copper to the shingle a thinner plate is possible.

The Anaconda has in mind certain improvements to be made at its electrolytic zinc plant at Great Falls, according to Frederick W. Laist, metallurgical manager, in which he said that the plans would result in better recovery, better current-efficiency, and lower operating and plant costs.—Butte & Superior recently won its appeal to the Montana State Board of Equalization in the matter of avoiding the payment of about \$45,000 taxes on ore which had figured in the compromise settlement with the W. A. Clark interests in the recent Elm Orlu-Butte & Superior litigation. The State Board permitted a deduction of the amount which Butte & Superior had paid to the Clark interests in settlement of the suit and which had been included in the Butte & Superior valuation, in the making of the Silver Bow county tax-rolls.

Troy.—The milling operations of the Snowstorm Mines Consolidated have been proceeding steadily for two weeks. Two carloads of lead-silver concentrate has been shipped to the smelter. Development, during the period of milling inactivity, on the No. 7 level, exposed ore for 1000 ft. Besides opening a long shoot of ore available, the No. 7 level effects economy in transportation. Trains of 4-yd. steel cars are backed to points under the chutes for loading and are dumped automatically in the mill with no further handling. The upper levels are connected with the No. 7, thus providing the same economical conditions for the movement of ore. The distance between the mine and mill is $5\frac{1}{2}$ miles. It is covered by a steam-railroad owned and operated by the company.—The Montana Morning Syndicate has opened a vein 15 ft. wide at the surface. The discovery was accidental and occurred when a pile of brush was removed. The new vein is 100 ft. east of the No. 2 shaft and contains lead-silver ore of high grade, according to reports.

NEVADA

Goodsprings.—Cobalt ore has been found here. The cobalt is present in the copper ores in this region, and in them only. Cobalt is not found in any of the ores of lead or zinc. The first cobalt was identified in a piece of ore from the Red Streak Mining Co., which resulted in the sampling of its dump, as well as in the prospecting for and sampling of other dumps. A number of chemists have identified the ore and a shipment of $1\frac{1}{2}$ tons was made. One carload of 40 tons is now being prepared for shipment by the Red Streak Mining Co. The cobalt is in the form of both sulphide and oxide. A number of independent operators are working the dumps of various mines.

Pioche.—According to James Quirk, superintendent of the Black Metals mine, high-grade silver ore has recently been opened in the northerly inclined stope starting on the 325-ft. level. Specimen pieces assay as high as 1000 oz. silver per ton. Average sampling of the face of the incline gave the following results: 8 ft. at top of stope-face, silver, 27.6 oz.; 8 ft. across bottom, silver, 35.2 oz. per ton.

NEW MEXICO

Las Cruces.—Seventy-five miners are now employed in the Chloride Flat district in Grant county. Wright, Stauha, Armstrong & Bell, and others are shipping ore. The first named are sending out seven cars per week. The entire mineralized area was worked over at a depth of approximately 80 ft. in early days, but with silver at a dollar per ounce it is profitable to ship lower-grade material.—De-

velopment work on the Volcan property continues. On the 300-ft. level, where a cross-cut is being driven, ore assaying 100 oz. silver has been found. The cross-cut on the 200-ft. level is showing 9 ft. of good ore and the other wall has not been reached. Work on the north face at the 200-ft. level exposed ore running from 40 oz. upward.

OKLAHOMA

Douthat.—In spite of the poor prices for ore, the Skelton Lead & Zinc Co. is now operating four of its eight properties at this place. The mines operating are No. 1, 4, 5, and 7.—The Admiralty Zinc Co. is operating two out of four properties here. It employs about 140 miners at the No. 2 and No. 3 mines, which have been operated throughout the low-price period. The zinc-blende is almost all of premium grade, reaching as high as 62.50% zinc content. The same interest owns the Sinden Zinc Co. mine at Cardin, which has been closed since March 1920, and the Queen Esther in the vicinity of Baxter Springs. The Admiralty properties are now under the management of M. B. Lawrence.—The Ramage Mining Co.'s mill here has been idle since September 1918. The Montreal, Quebec, and McClelland tailing-mill has been closed for several months. The Federal mill has been idle for over a year. Some parties took an option on the property recently, but did not make a trial-run.—The Fort Worth mine, owned by J. C. Squires & Co., situated in North Century, resumed about a month ago and is using about 40 miners. They are working at a depth of 210 ft. Glenn R. Squires is superintendent.—The New Chicago mine, situated east of Douthat, has been working since July 18 and is employing 80 miners. Its ore is at 140 ft.; this is shallow compared to other mines in this vicinity.

OREGON

Baker City.—Several shoots of silver-gold ore, ranging in value from \$5 to \$50 per ton, have been opened on the Black Bear group of claims, situated on Elkhorn mountain, by W. S. McQuain. The vein that he has been developing is from 5 to 12 ft. wide, and the outcrop can be traced for 2000 ft. The property is nine miles from Haines, the nearest railroad point, and is at an elevation of 5950 ft. The building of a road one-half mile long will connect the property to an excellent highway. Water for milling and timber for mining are available on the property.

UTAH

Alta.—One of the largest consolidations of mining companies made in Utah during recent years was completed on October 19, when articles of incorporation were filed by the South Hecla Mines Co. This company will take over the South Hecla, Albion, Alta-Utah, and South Hecla Extension properties. The South Hecla stockholders will receive four shares in the new company for each share now held; the Albion stockholders will receive share for share; Alta-Utah stockholders, one share of new stock for two and one-half shares now held; South Hecla Extension stockholders, one share of new stock for each eight shares now held. The capitalization of the new company is 5,000,000 shares, 2,000,000 of which will be used in taking up stock in the four companies involved in the consolidation. The remaining 3,000,000 shares will be held in the treasury. The par value of the shares is 10c. The acreage of the new company is about 1300 and includes practically all of the mining ground in the south half of this district. There has been driven in the four properties between 10 and 12 miles of tunnels, shafts, winzes, raises, etc., and the gross value of the ore produced to date is about \$4,000,000. George H. Watson, president of the new company, states that the consolidation is for the purpose of securing more efficiency and economy in operation. George F. Wasson is vice-president;

Robert F. Marvin, secretary-treasurer; A. B. Watson and J. Will Knight, additional directors.

The Alta Transportation & Tunnel Co. has contracted for the hauling of a minimum of 10 tons of ore per day during the remainder of the shipping season, which usually lasts until Christmas. Shipments at present to the Murray smelter give net returns of about \$40 per ton.

American Fork.—The Silver Contact Mining Co. owns three claims on the south side of American Fork canyon, on one of which an inclined shaft was sunk about two years ago. Ore said to average \$65 per ton in silver and lead was uncovered, but a cave-in caused operations to be suspended. A tunnel has been started about 150 ft. below the shaft, and is now in a distance of 100 ft. Officials believe an orebody will be reached within the next hundred feet. C. G. Balfantyne is president.

Eureka.—Hugh Trenholm, manager for the various Knight interests, reports that the Iron Blossom and Colorado mines are attracting a large number of lessees; at present the working forces are much larger than they have been at any time during the past year. A contract has been let for a drift through a portion of the Dragon property, where a cave-in stopped production of ore. When this drift is finished, ore shipments to the Tintle Milling Co. will be resumed.

Ore shipments for the week ending October 15 totaled 142 cars, as against 178 cars for the preceding week. The Tintle Standard shipped 61 cars; Chief Consolidated, 33; Iron King, 10; Eagle & Blue Bell, 8; Iron Blossom, 7; Victoria, 7; Swansea, 4; Centennial-Eureka, 4; Colorado, 3; Bullion-Beck, 2; Eureka Mines, 1; Alaska, 1; and Sunbeam, 1.

Park City.—Seventy-five men are now employed at the Park-Utah mine, and this number will be increased, according to Paul Hunt, superintendent. A bunk-house, 28 by 58 ft., sufficient to accommodate 40 men, is being constructed and will be ready for occupancy early in November. Conditions in the mine are satisfactory.

During the week ending October 15, the Judge allied companies made the heaviest shipments of ore in many months, a total of 1051 tons being sent to the valley smelters. The Silver King Coalition shipped 829 tons and the Ontario 310 tons, making the total output 2190 tons, as against 1923 tons for the preceding week.

Good progress is being made in the construction of the milling plant at the Silver King Coalition property, according to M. J. Dailey, mine-manager. The structural-steel work is completed, and about 60% of the galvanized-iron sheeting has been placed. The crushers and rolls have been installed. It is expected the plant will be ready for operation about January 1. Exploratory work on the 1450-ft. level of the mine, in the M. L. M. fissure zone, is gratifying. High-grade silver-lead sulphide in a vein averaging 3 ft. thick has been opened.

Wendover.—Mining activity is being resumed in the Silver Island district, a short distance north of this station. W. W. Fowler has just completed a contract for tunnel work in the 'Hole in the Wall' claim. Samples taken from the face of the tunnel assayed 128 oz. silver and 18.3% lead. In the Salisbury mine, in the same district, Mr. Fowler reports that an 8-in. streak of ore has been opened, assaying 153 oz. silver and 17% lead. Development work will be continued in both mines.

WASHINGTON

Chewelah.—The United Silver-Copper Co. has followed high-grade silver-copper ore for 65 ft. on the 1400-ft. level, according to E. A. Wolfe, manager. Also it has followed ore of the same grade in a winze sunk 25 ft. below this level. The high-grade streak is 18 in. wide and contains an

average of 70 oz. silver per ton and 11% copper. The winze will be continued to the 1500-ft. level, but the progress will be slow, as but one shift of two men is employed.

Oroville.—More activity is being shown in mining in this district than for 10 years, according to Horace R. Smalley, who is interested in the Rainbow group. He estimates that about 150 miners are now employed in the mines around Oroville. The ore is silver-lead, rich in silver. Most of the mines are shipping to the Tacoma smelter. There is some talk of trying to interest British Columbian mines now idle in forming a smelter company to take over the Northport smelter if a lease can be secured. By shipping to Northport the freight-charges would be cut in half. Resumption of operations at Northport would also encourage other mine-owners in the northern part of the State to resume operations.

ALBERTA

Pouce Coupe.—Later details of the find of natural gas in the well that the Imperial Oil Co. is drilling at Pouce Coupé, in the Peace River region, near the boundary-line between Alberta and British Columbia, indicate that the discovery is likely to prove important. After the initial flow, which was estimated at two million cubic feet per day, the boiler was moved back from the well, as ignition of the gas was feared. About 15 minutes after re-starting the drill another heavy flow of gas developed, estimated at 8,000,000 cu. ft. daily, which sent particles of tar-sand high into the air. After this second strike work was suspended, pending instructions from headquarters. It is thought likely that a 'commercial' flow of oil may be 'brought in'.

BRITISH COLUMBIA

Prince Rupert.—Heavy rains followed by swollen rivers have done some damage in the northern part of the Province. The cable-ferry across the Skeena river at Terrace was carried away and smashed to pieces on the rocks. Bridges over the Bear and Salmon rivers are reported to have been carried away, and several of the bridges on the Alice Arm-Dolly Varden railway are reported to have been undermined, though the extent of the damage has not yet been ascertained.

Rossland.—Several hundred pounds of ore that carried 183 oz. gold was shipped from the I. X. L. mine recently. Eight men connected with the Consolidated Mining & Smelting Co. took a three-year lease on this mine. In cross-cutting they found stringers of rich ore.

Trail.—In the first nine months of 1921 the smelter of the Consolidated Mining & Smelting Co. of Canada received 307,493 tons of ore, compared with 251,735 tons in the same months of 1920 and 258,323 tons in the first nine months of 1919. Most of the ore is coming from mines owned by the company; 7629 tons came from other mines.

MEXICO

Chihuahua.—R. E. White, president of the R. E. White Mining Co., has called for a general meeting of stockholders to be held in the offices of the company in this city on November 3. A report of the past year's operations is to be rendered and a new board of directors will be elected.

Eduardo W. Enriquez has recorded application for the Hidalgo group of mines in the Urique district. The survey is to include the old La Chicharra and El Salto mines, which have been abandoned by the former owners.

General Ignacio Enriquez, governor of the State of Chihuahua, proposes to construct a telephone line to connect the principal mining camps in the remote western part of the State. The line will be about 475 km. long and will extend from Batopilas to Urique, Guazapares, Palmarejo, Rio de Plata, and thence to the station of Creel on the

Kansas City, Mexico & Orient railroad, where it will connect with the Federal telephone lines. The State government has also taken over the telephone line between the City of Chihuahua and the mining town of Santa Eulalia and is repairing it for constant and efficient service.

Durango.—Due to the probability of the Torreon smelter, owned by the Cia. Minera de Peñoles, and the Velardeña plant, of the American Smelting & Refining Co., resuming operations soon, and the continued advance in the price of silver, mining throughout the State is becoming more active.

A number of new filings have been made during the past week in the various districts. M. J. Bernard has located six new claims to be titled under the name of Tecolotes, which embraces the old abandoned Murecilagos properties in the San Bernardino district.—Gerald E. Norton, of Durango City, has denounced El Salvador group of gold and silver mines in the vicinity of Pueblo Nuevo.—Juan F. Martinez and associates have taken up three claims in the Todos Santos mountains in the Guanacevi district, which are to be patented under the name of Verdadero Faro.—Jose Calderon has discovered and located some tin mines in Los Remedios mountains a short distance west of the City of Durango, which he is developing.

NIGERIA

Jos.—The output of tin for Nigeria will be under normal for 1921, on account of low prices and high costs of material. Some mines have stopped producing, others have greatly reduced output. Ropp Tin, Ltd., is possibly the only company that will show an increased output. Almost every company producing will show a decrease in costs.

Some excitement has been caused by reported gold discoveries; no finds of high-grade ore have been confirmed. Gold has been found over a great part of Northern Nigeria, and possible payable lodes may be found.

ONTARIO

Cobalt.—The Nipissing during the first nine months of 1921 produced approximately 2,022,000 oz. of silver, or about 15% below the output of 1920. In money value the production is about one million dollars behind. Since May, however, there has been a steady improvement in the output, and the prospects for the remainder of the year are good. During September the company mined ore of an estimated net value of \$197,536, of which \$25,050 was cobalt, and shipped bullion from Nipissing and customs ore of an estimated net value of \$164,405.

At the Victory preparations are being made to deepen the shaft from 200 ft. to the 500-ft. level. A cobalt vein carrying some silver was cut at 185 ft., and will be picked up at depth.

The new shaft of the Oxford-Cobalt on the Waldman is down 50 ft. Three small veins paralleling on the surface have joined and at the bottom of the shaft the vein is 2½ in. wide, but the silver content is lower.

Porcupine.—It is stated that the Ontario government has given the Temiskaming & Northern Ontario Railway Commission the right to develop power in the neighborhood of the Big Bend on the Abitibi river. It is proposed to utilize the power for the electrification of the road and offer the surplus for sale to the mining companies or other consumers. The capacity of the falls is estimated variously at from 15,000 to 30,000 horse-power.

The Porcupine-Davidson has appointed George E. Bent manager and before sinking the main shaft is endeavoring to determine the position of the main orebody below the 1200-ft. level by diamond-drilling. Drifting is also being undertaken on the 600-ft. level. The working force is being largely increased; plans for a 500-ton mill are nearly completed.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Norman Stines is at Seattle.

J. B. Tyrrell was at Kirkland Lake recently.

W. E. Thorne has returned to London from Jos, Northern Nigeria.

W. H. Wellman has returned from Parral, Mexico, to Los Angeles.

C. V. Corless has returned from England to Coniston, Ontario.

Walter Fitch, president of the Chief Con. Mining Co., is in New York.

S. Becker has moved from Sheep Ranch to Berkeley, California.

F. L. Sizer has returned to San Francisco from the Grass Valley district.

Ben. H. Cody has moved from Ajo, Arizona, to Excelsior Springs, Missouri.

Howard D. Smith was at Ruth, Nevada, last week, and is now in New York.

E. R. Hadie, Jr., of San Francisco, is at Katherine, near Kingman, Arizona.

C. W. Purington expects to sail from Vancouver for Siberia on November 18.

Arthur R. Weigall is expected in San Francisco at the end of this month, from Korea.

M. E. Cooley has been elected president of the Federated American Engineering Societies.

Frank G. Stevens is now engineer for the Makeever Brothers, with headquarters at Boston.

C. W. Adams, manager of the A. S. & R. smelter at East Helena, Montana, was at Salt Lake City last week.

Warren R. Sholes, of Murray, Utah, has been appointed Mineral Examiner of Utah for the U. S. Land Office.

Charles R. Davies is with the Mexican Corporation, at Fresnillo, Zacatecas, having left Salt Lake City, Utah.

Samuel W. Cohen was the official representative of the University of Minnesota at the McGill University centenary.

A. E. Perkins, Western manager for the Colonial Steel Co., has recently returned from an extended trip through Alaska.

J. E. Rypinski, recently at the Vipont mine, at Oakley, Idaho, is now with the Silver King Coalition Mines Co., at Park City, Utah.

Ross Taylor, assistant mill-superintendent for the Nevada Consolidated Copper Co. at McGill, was at Salt Lake City recently.

Henry Newell, of Ocean Park, California, a director of the Silver King Coalition Mines Co., has been spending some time in Utah.

R. C. Gummell and D. D. Moffat are making a tour of inspection of the Ray Consolidated and Chino Copper companies' properties in Arizona and New Mexico.

H. Kenyon Burch has recovered completely from a recent operation and will return from Los Angeles to Warren, Arizona, on November 1.

Joseph William Richards, Professor of Metallurgy in Lehigh University, died on October 12. He was born in England and was brought to this country at an early age, being educated in Philadelphia and at Lehigh University, where he was appointed assistant instructor in metallurgy in 1887, and professor of metallurgy in 1903. He was the first president of the American Electrochemical Society and an author of distinction. His death is a great loss to Lehigh University as well as to American technology.

EASTERN METAL MARKET

(By wire from New York)

October 24—Copper is quiet and easier. Lead is steady and firm. Zinc is less active but easier.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

GROWTH OF THE ELECTRICAL INDUSTRY

Speaking at the Harvard Club recently Merle R. Griffith, of the General Electric Co., stated that \$1,000,000,000 new capital is needed each year, \$3,000,000 per day, \$125,000 an hour, for generating, transmission, and distribution equipment by the electric lighting industry of the United States. If capital for customers' lamps, motors, appliances and for wiring houses and factories is considered, twice this sum will be required.

The electrical industry is less than 40 years old. It doubles every five years. Five dollars of new capital is required for every dollar of new business. Business in electrical merchandise was two billion dollars in 1920. There are 21,000,000 homes in the United States, 7,000,000 are wired and 14,000,000 are prospects for \$750 each in wiring and electrical merchandise. The value of washing-machine motors in 1912 was \$7,000,000, in 1920, \$50,000,000.

The invention of the Mazda lamp with a tungsten filament has saved the people of this country \$1,195,200,000 yearly which otherwise would have been expended to produce the same amount of light from the old carbon filament lamps. These figures are based on 100,000,000 lamps manufactured in a recent year. In 1920 270,000,000 incandescent lamps were manufactured in this country, 140,000,000 of which were automobile lamps.

The Edison Electric Illuminating Co. of Boston uses 2,000,000 lamps per year, 95% of which are Mazda type. The company has 130,000 customers and there are 110,000 meters installed in a territory embracing over 600 square miles.

Twenty-nine years ago the largest power generator manufactured was 275 hp. Today there is in operation a steam turbine of 45,000 kw equivalent to 60,000 hp. The first generator could supply 2000 incandescent lamps, the last generator, 2,500,000. The potential water horsepower of this country is 60,000,000. Only a little over one-tenth has been developed. For every horse-power developed from our streams a saving of from 5 to 13 tons of coal is made in a year. Niagara Falls represents a potential horse-power of 5,000,000, figuring at the low price of \$10 per horse-power this would be \$50,000,000.

The Montana Power Co. saves 2,000,000 tons of coal per year or 5500 tons daily by using water-power. On the Rocky Mountain and Missoula Divisions of the St. Paul railway, 425,000 bbl of oil and 200,000 tons of coal are saved yearly by utilization of water-power. The electrical equipment of one battle cruiser develops 180,000 hp. Should one be anchored in Boston harbor, it could supply the entire city with power and lighting facilities. Four could supply the city of New York. The annual department store sales are \$2,094,000,000. The annual liquor sales were \$2,458,000,000. The electrical industry is endeavoring to obtain a good portion of the money that was formerly dissipated in the purchase of liquor.

MONEY AND EXCHANGE

Foreign quotations on October 25 are as follows:

	Demand	3.97 1/2
Franc, cents:	Cable	7.43
	Demand	7.45
Lira, cents:	Demand	4.05
Mark, cents:		0.68

Eastern Metal Market

New York, October 19.

Columbus Day, October 12, was observed as a holiday here; immediately afterward a slackening in demand for most of the metals developed and still obtains.

The copper market is less active but prices are steady and a good latent demand is said to exist.

Moderate buying of Straits tin continues and prices are higher.

The lead market is quiet but steady to firm.

The tendency of the zinc market continues higher with demand good.

Antimony is inactive.

IRON AND STEEL

Producers and consumers of steel appear little disturbed by whatever prospect exists of a general railroad strike, according to 'The Iron Age'. On the one hand there has been no flurry of orders for prompt shipment; on the other hand the strike threat has not stopped buying for other than immediate delivery. Generally, the market has been quieter than in the past two weeks. Some manufacturing consumers of pig-iron and steel who could deliver their own product by truck, in case of strike, have made an effort to ensure supplies of raw material. Perhaps in sheets more than in other rolled products, mills have been asked to expedite deliveries. Wire nails, in which the final distribution is local, have also been called for in the same way.

The belief that in some way a strike will be averted accounts in part for the generally even tenor of the market. A greater influence than the strike-threat itself is the practical certainty of freight-rate reductions. Its effect is seen in some withholding of shipping orders.

COPPER

The market has turned quiet. There is still a good inquiry and considerable latent business, but there is by no means the activity which has characterized the past three or four weeks. Producers have sold themselves into a comfortable position and most urgent needs of consumers are supplied. Because of the prospective railroad strike there are some cases of requests for a speeding-up of shipments, but the effect otherwise has been unimportant. Prices for electrolytic copper are steady at 12.75c., New York, or refinery, or 13c., delivered, though a week ago most sellers were asking and obtaining 12.87½c., New York, or 13.12½c., delivered. Sales to foreign countries continue satisfactory, with the Far East the principal buyer. One seller reports a substantial amount of prospective business before him which will probably materialize as soon as the problem of the railroad strike is settled.

TIN

For several weeks now there have been substantial sales of Straits tin, with consumers purchasing a large portion; this movement continues. On the whole, the week has been a quiet one with sales confined to two days—Thursday and Friday. On the former day about 100 tons of spot Straits was sold at 27.25c., New York, and on the latter about 150 tons of future shipment at 27.75 to 28c., mostly to consumers in both cases. On October 13 there was some business in tin, ex-steamer at dock, at 27.12½c., and there were buyers but no sellers of far-future shipment at 27.62½ to 27.75c. One difficulty in getting future-delivery tin is the fact that London houses are ready buyers and take all they can get. Spot Straits yesterday was quoted at 28c., New York. The London market was strong with spot standard quoted at £157 5s., future standard at £159 10s., and spot Straits at £157 15s. Arrivals thus far this month have

been 1895 tons with 3430 tons reported afloat. Shipments from the Far East to all countries for October 1 to 15 have been 2235 tons.

LEAD

The market is featureless as to developments but a steady demand continues with prices firm. The leading producer continues to take business at 4.70c., New York and St. Louis, while independents are asking a slight premium in the East but selling at around 4.50c. in the West.

ZINC

The market continues strong and moderately active with prices advancing almost daily. Nearly all producers have sold their October output or as much as conditions warrant. This, combined with the fact that they are not generally drawing on stocks made at high prices, is the cause of the present continued stiffness. Prime Western for early or 30-day delivery is quoted at 4.67½ to 4.70c., St. Louis, or 5.17½ to 5.20c., New York, with business done at the lowest levels. There is a large inquiry for brass-special zinc, aggregating about 3000 tons spread over several months delivery, but none has been contracted for yet.

ANTIMONY

The market is quiet with wholesale lots for early delivery quoted at 4.90c., New York, duty paid. This could probably be shaded on desirable business.

ALUMINUM

There has been no change, the leading producer quoting 24.50c. f.o.b. plant for wholesale lots of virgin metal, 98 to 99% pure, with the same grade obtainable from importers at 17 to 18c., New York, duty paid.

ORES

Tungsten: The market is stagnant and prices are nominal at \$2.75 to \$3 per unit for Chinese ore and \$3 to \$3.50 per unit for South American wolframite.

Molybdenum: There is no activity and quotations are nominal at 48 to 50c. per pound of MoS₂ in regular concentrates.

Manganese: An absolute lack of demand, because of previous contracts and large stocks, renders quotations nominal at 20c. per unit, seaboard, for high-grade foreign ore.

Chrome: One seller quotes foreign chrome ore at \$20 to \$26 per net ton, c.i.f. Atlantic ports, nominal, and depending on analysis.

FERRO-ALLOYS

Ferro-manganese: Both British and American products are quoted on a basis of \$58.35, seaboard, and there is almost no business. Attempts are being made to solicit a group of buyers to take British alloys at \$50, seaboard, and it is stated that American makers have expressed a willingness to meet this, if consummated.

Spiegeleisen: There have been sales of about 400 tons of 19 to 21% alloy at \$26 furnace, for delivery this year. Quotations range at \$25 to \$26, furnace.

Ferro-tungsten: There is very little demand. The domestic product of standard analysis is quoted nominal at 40 to 45c. per pound of contained tungsten, f.o.b. plant, while the foreign alloy is held at 50c., duty paid, seaboard.

Ferro-silicon: The 50% alloy is quoted at \$60 to \$65 per ton, delivered, and there have been moderate sales.

Ferro-chromium: The regular 60 to 70% alloy, containing 6 to 8% carbon, is quoted at 11c. per pound of contained chromium in wholesale lots, while the 4 to 5% carbon alloy is held at 11 to 12c., both f.o.b. plant.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE 'LITTLE TUGGER' DERRICK

Necessity recently fathered the invention of an inexpensive derrick, and at the same time showed another novel use of the 'Little Tugger' hoist.

Fire gutted the 600-ton mill of the Silver King Coalition Mines Co. This mill concentrated the ores from the company's mines, which are situated at Park City, Utah, about 35 miles south-east of Salt Lake City.

Two 'Little Tugger' hoists were used in the construction of the derrick for clearing away the debris to make room for the new mill which is now being erected. This derrick was used to lift all of the heavy material. The hoists are small, compact drum-hoists operated by compressed air or steam. Originally they were used in the company's mines; they were first put on the market as portable mine-hoists.

Following is a description of the derrick and the work:

Improvised Derrick, Lifting Half of a Marcy Mill

The mast *a* and the boom *b* were both made from telegraph poles. The mast is carried at the foot by the pivot *d*, held by the guy-ropes *e*. The boom is pivoted at the lower end of the mast. The rope *f* is connected with the upper hoist and passes over the sheave *g* at the top of the mast and through pulley *h* at the mast-head and *i* at the bottom of the boom. This rope varies the angle of the boom.

The hoisting-rope *j* is connected with the lower hoist and passes under the sheave *k* on the mast, over sheave *l* on the boom and through the pulleys *m* and *n*. This is the rope which suspends the load.

The derrick is swung by hand, although another 'Little Tugger' could do this work also if it were desired. In this

case the derrick would have to be furnished with a bull-wheel.

The installation photograph shows the derrick in action. One-half of a No. 64½ Marcy mill has just been lifted clear of the ground. It was used in clearing away about 90% of

Arrangement of Hoists, Poles, and Tackle to Make a Derrick

the wreckage from the fire. With the pulley arrangement shown, the derrick is capable of lifting approximately a 3-ton load. This, of course, may be varied to suit conditions.

HARDINGE COMPANY PUBLISHES A NEW CATALOGUE ON PULVERIZED FUELS

A bulletin entitled 'Pulverized Fuels' has just been published by the Hardinge Co. This bulletin is known as the No. 9 Catalogue. The Hardinge conical mill, although only recently applied to this work, has been fully demonstrated as a most satisfactory unit for pulverizing solid fuels. This bulletin is divided into three main sections: the application of pulverized fuel to various burning problems; the principle of operation of the Hardinge mill; and a discussion of the application of the Hardinge system for pulverizing fuels.

Under the first heading three principal causes are mentioned for the advance in the use of this class of fuel in the last few years. The reasons are:

- The increased efficiency of combustion.
- The utilization of fuels which would otherwise be wasted or be inefficiently burned.
- Flexibility of operation and ease in handling, making it possible to control the burning within a wide range on short notice.

In the general discussion of pulverized fuel where the Hardinge system is used, emphasis is laid upon the point of 'sparking' during the burning process. The book emphasizes the point that when coarse oversize of from 65 to 150-mesh, depending upon the character of fuel, is eliminated, 'sparking' ceases, and when this oversize is eliminated by a satisfactory means, it is not necessary to grind to a degree of fineness which was at one time thought necessary.

Under the head, 'The Hardinge Mill', the general principle of grinding is discussed, with special reference to stage-reduction, elimination of the fine particles as soon as produced, and the proportioning of energy to the work required. The different types of Hardinge mills and the details of their construction are also discussed in this section, and special reference is made to the advantages of the conical mill when used for pulverized fuels of widely different character.

Under 'Pulverized-Fuel Installations', a complete pul-

is now progressing on the building. The analysis of the new 'Ampec' bronze is approximately 5% aluminum, from 13 to 50% steel, and from 43 to 70% copper, together with necessary amalgamating alloy. This new bronze is bright yellow in color, possessing a tensile strength of upward of 68,000 lb per square inch; has a scleroscope hardness of from 28 to 45 points dependent upon the grade produced; pours readily, and is free from blow-holes and oxides. It is readily forged, drawn, or rolled; can be welded with either acetylene or electric process, and can be cut with a welding tip. It machines more freely than cold-rolled steel; readily takes on a very high polish and is acid-resisting to a marked degree. It solders as readily as steel.

Its specific gravity is 7.43, making it from 20 to 25% lighter in weight than ordinary bronzes. It has splendid qualities as bearing and bushing material. A number of bushings being installed on tests, are being run absolutely dry. Other bearings, lubricated, have had upward of a month's service in places where ordinary bearings break

Typical Arrangement of Coal-Pulverizing Plant with Hardinge Mills

verized fuel-plant is outlined, which includes the feeding of the coal from the track hopper to the crushers, dryers, mill, separator, and distribution system. There is also taken up different arrangements of the mill and separator which would be used according to the special requirements. In addition, there is given a table showing the general dimensions of the different sizes of Hardinge mills, so that it is possible to make a rough estimate of the floor-space required for each unit. The accompanying illustration shows a typical arrangement of a coal-pulverizing plant using the Hardinge system.

A BRONZE WITH 50% STEEL CONTENT

The American Metal Products Co., of Milwaukee, which has for the past six years been engaged in producing aluminum-bronze castings of approximately 84% copper, 10% aluminum, and 6% iron, has successfully blended another alloy which will be placed on the market immediately upon the completion of its new 80 by 220-ft. foundry, and as soon as proper electrical-melting equipment is installed. Work

down in ten days, and show no marked signs of deterioration. Because of the low price of the steel in this composition, the new metal will naturally sell for a price less than the price of ordinary bronze in either pigs, billets, or casting form.

Bulletin 56-X, 'P & H Excavating Equipment', is the title of a new publication of the Pawling & Harnischfeger Co. This booklet summarizes the achievements of the P & H line in road-building, in general excavation and in all phases of engineering activity in which earth handling is a prime factor. The P & H line ranges from the heavy-duty type of machine used in the reclamation service to the compact back-filler for closing trenches. Bulletin 56-X contains records and illustrations of the actual performance of P & H excavators under widely divergent conditions of service and application, and in the varying climate and topography of different sections of the country.

The firm of J. Santos, Lda., of Lisbon, has been appointed exclusive agent for the Novo Engine Co., of Lansing, Michigan. Its territory will include the whole of Portugal.

T. A. RICKARD, . . . Editor

IN this issue we publish another article, on mine-sampling, by Mr. Morton Webber. This one saw the light elsewhere six years ago, and we re-print it because so many requests have been received for copies of it in its original form, now out of print, in 'The Mining Magazine'. We asked Mr. Webber to revise it and to add to it; this he has done. In a later article, entitled 'The Combination Method of Mine-Sampling', appearing in our issue of February 28, 1920, Mr. Webber suggested a remedy for the correction of the latent errors, dealing with specific cases within his own experience. Referring to the article in this issue, we may say that the second example quoted by Mr. Webber is based upon the Aurora Consolidated fiasco in Nevada. We understand that Mr. Webber examined the mine and advised his clients to offer \$100,000 more than the price asked for the property, provided six months were given to do the necessary cross-cutting mentioned in the article. The additional time was refused and the property was acquired by others. In the sequel it was proved that the additional six months for exploratory work was worth \$100,000 in a deal of such magnitude.

AN engineer, after visiting one of the large copper mines in Chile, aired his views in our columns recently as to the reasons for the heavy turn-over of American officials on South American properties and the frequent rupture of contracts between employer and employee. He maintained that men usually take positions abroad because the life at home lacks something that can be obtained by going farther afield; in some cases it is a measure of freedom they are looking for, or they need experience; in others, additional recompense is the deciding factor. A few migrate thoughtlessly, giving no heed to what will be required of them. The average young American mining engineer is peculiarly situated; he can get, in the United States, all the experience in mining and metallurgy he needs; in many cases if he goes abroad he misses the hundred and one advantages of home life; and, unless the normal rate of pay is unusually high, he is inclined to think that he has a grievance. The conclusion reached in this particular instance was that the company in question appeared to have done everything possible to ensure that their men were contented and satisfied; in those cases where failure had resulted, the cause was shown to be due to temperamental

influences over which the officials have little or no control. These conclusions are endorsed, in the current issue of the 'Professional Engineer', by an employee of the Chile Exploration Company, the corporation on which our contributor made his comments, and who prefaces his remarks by stating that he has received a 'square deal'; the company, he maintains, tries to give its employees all they can justly ask. He then puts several pertinent questions to those who contemplate taking a position abroad. Aside from how the company may treat you, he asks, what pay you are to get, and other like considerations, will you be contented in the place in which you are to live? Will you pine for Forty-Second street and Broadway? Will you miss the city life? If you are married, will your wife be contented? This question is emphasized as one of vital importance. How long do you intend to stay? The employee gains little and the company loses much as a result of abbreviated periods of employment abroad. Too many of the dissatisfied ones—and travelers on the west coast of South America meet such men frequently, although less frequently than formerly—have been hasty in going abroad.

VARIETY and interest continue to characterize the contributions to our discussion columns. Mr. A. J. Bone calls attention to the fact that the blast-furnace still merits recognition for the efficient and economical treatment of copper ore; he emphasizes the feasibility of smelting sulphide concentrate in the blast-furnace after preliminary nodulizing. The respective merits of reverberatory and blast-furnaces have been the subject of much discussion; the adherents to reverberatory practice might be inclined to retort that it is the exception that proves the rule. Mr. Bone is right, of course, when he says that the issue is "between direct smelting and concentration". Mr. Ernest Gayford, of Salt Lake City, discusses the relation between the amount of lime added and the extraction of gold and silver by cyanidation. An excess of such alkali has been blamed by many metallurgists as a cause for the re-precipitation of gold; but the subject is one on which it would be dangerous to generalize, for conditions vary to an amazing extent, and seldom are two ores or two working cyanide solutions exactly alike; neither are operations duplicated other than in exceptional instances. The figures given by Mr. Gayford appear to offer conclusive proof as to the ill

effects of an over-dose of lime; nevertheless, we would venture to suggest that the better plan would be to estimate, by experimentation or from empirical data, the degree of protective alkalinity in the solution that corresponds with efficient extraction, and to maintain this uniform by means of frequent testing and by regulating the addition of lime in accordance with the results. It is not invariably the amount of lime that is added that affects extraction but the resulting alkalinity of the solution, and this is liable to vary hourly as a result of changes of conditions. Mr. R. B. Brinsmade makes some interesting comments on the question of the exemption from tolls of American ships passing through the Panama Canal. Mr. A. H. Jones replies to Mr. Algernon Del Mar on the subject of the flotation of gold and silver, making pertinent comment on the respective results of experimentation and practice. Gold and silver that have been ground finely appear to be amenable to the flotation process, but to us it seems that the field of application is a very limited one, when comparison is made with results being obtained by alternative methods. Nevertheless, concentration often is a necessary preliminary to another and more extractive form of treatment, so that research and investigation are justified. Mr. A. W. Fahrenwald, who recently contributed to our columns a paper on surface-energy and adsorption in flotation, replies to comments made by Mr. A. C. Halferdahl. A better understanding of the fundamental theory underlying the flotation of mineral is to be desired, hence we welcome further discussion on this interesting subject. A correspondent, who prefers to remain anonymous, takes issue with Mr. Paul R. Cook as to the respective abilities of the so-called practical man and the proficient writer to convey technical information in a concise manner; he maintains that conciseness is not a distinguishing feature, much less the monopoly, of the so-called practical man.

The Futility of War

In our last issue we reviewed Mr. Norman Angell's book, 'The Fruits of Victory'. This book ought to be read by every thoughtful man, for it is a sincere and reasonable statement of the conditions produced by the recent war and is an effective sequel to the author's previous volume, 'The Great Illusion', in which he argued that war in the modern world was a gigantic futility. He pleads for the co-operation of the nations in logical recognition of their interdependence, and insists earnestly that to fight among themselves, with the intensity permitted by modern methods, is suicidal. We in this country know something about war, but not nearly so much as the less fortunate peoples across the water; the Great War drew us into it, but our participation was brief and we were spared the loss of life, the horrors and the humiliations, the cruelties and the destructions that scarred the face of Europe. Nevertheless, most of us have some imagination and have read enough on the subject to receive with sympathy such a book as Mr.

Angell's, in which the dire effects of a perverted nationalism are set forth in plain and convincing language. The dry eloquence of statistics will be additionally impressive. During the four years of the Great War the loss of life, in soldiers only, not civilians, was 9,980,000, or, in round numbers, ten million lives. This does not include the millions of civilians that were killed or that died of disease and starvation. Our Civil War took a toll of 700,000 lives and the Franco-Prussian war only 184,000. Warfare has ceased to be a game between small armies of professional soldiers; it is a fight to the death between whole peoples. The loss of money in the Great War is estimated at 186 billion dollars; it increased our national debt from 1028 to 24,974 million dollars; it increased that of Great Britain from 3485 to 39,314 million dollars; and it increased the debt of France from 6346 to 46,025 million dollars. All the big wars of the world between 1793 and 1910 are estimated to have cost only 23 billion dollars, according to Mr. Will Irwin, whose book 'The Next War' is, as its sub-title states, an appeal to common sense. In a little over four years the warring nations spent eight times as much as in the preceding 117 years, and that does not include the value of private property that was destroyed nor the value of the human lives that were obliterated. According to a recent statistical valuation, an average human being in this country is worth economically \$5800. Again the figures are staggering, if we multiply even a much smaller unit-value by the fifteen millions, soldiers and civilians, who were destroyed by the Great War. Nevertheless the reality of the loss is being brought home to most people more by taxation than by statistics. Of the actual expenditures of the United States during the fiscal year 1919-1920, no less than 93% of the total national revenue went to pay for past and future wars; the existing army and navy absorbed 38%, and payments on account of past wars took 55% of the entire revenue. Even the least thoughtful of citizens is beginning to appreciate, through his pocket-nerve, what war means to him. The United States spent \$826,337,939 for military (army and navy) purposes in the fiscal year that ended on June 30, 1921. For the succeeding fiscal year appropriations of \$830,000,000 have been made. In forty years, at this rate, we shall have spent 33 billion dollars, which is equal to the whole amount of the reparation that Germany is compelled to pay during the same period. Meanwhile the Germans are saved the cost of an army and navy, and can devote themselves entirely to productive industry. Thus the victor pays, as well as the vanquished, and in the end no one gains. The conclusion is inescapable. Nor is the cause of war the lust for territory or spoils, as in the olden time; our modern warfare is the outcome of a senseless exaggeration of a sentiment that is worthy if disciplined; it is the consequence of an insane nationalism, which ignores the fundamental fact of the interdependence of the nations of the earth. That is Mr. Angell's chief argument. As religious bigotry and sectarian vindictiveness have given place to tolerance in matters of

spiritual belief, so the nations must learn a larger generosity and a sorer forbearance in their political and economic dealings with each other. The love of one's native land should not necessarily be accompanied by a suspicion or hatred of other lands. If we do not behave ourselves, life on this planet will become intolerable. The next war, which none of the great Powers can escape, if the idea of disarmament be not accepted, will involve losses in life, money, and happiness even more tremendous than the recent Armageddon. The possibilities of death-dealing machines, of attack under water and in the air, of bombing and poisoning, stagger the imagination. The horrors of the dark years, 1914-1918, are but a suggestion of those that must be expected when next the nations join in the death-grip. What would a dweller on Mars think of the inhabitants of this planet if he saw our antics? Humanity—particularly the part we denominate 'civilized'—is like a shipwrecked group of people on a small island in mid-ocean. The island is infested with wild beasts and plagued with fevers; without organized cultivation it will not produce sufficient food for the castaways, and it has a climate that requires them to build shelters; even the supply of fresh water is inadequate unless they unite in sinking a well or in building a reservoir. What would we think of these unfortunates if they were to disagree among themselves continually; if they classified themselves into blondes and brunes, and fought against each other under these colors; if the men quarreled with the women; if the tall fellows joined to kill those of short stature? We would dub them lunatics. If then they refused to join in building shelters, and in providing themselves with a sure supply of water; if they made no joint effort to prevent disablement from malaria; if they could not agree how to repel the wild beasts of the island? We would consider them worthy of the fate that surely would befall them. Do we belong only to the genus *homo* or are we entitled to sub-classification as the species *sapiens*? We tamed the brother of the wolf so that he became the guardian of the flock; shall we confess an inability to tame ourselves? Of what use is all our progress in the arts and sciences if we revert to the instincts of the jungle?

Cyaniding Pyritic Ore

In so far as contributions to current technical literature are concerned, the presidents of engineering societies usually rest on their laurels. Not so, however, Mr. F. Wartenweiler, the newly elected president of the Chemical, Metallurgical, and Mining Society of South Africa, the notice of whose preferment appears in the same issue of the society's 'Journal' as does an excellent paper on the distribution of gold in the classified products of the ores mined on the Witwatersrand. A transition from an oxidized to a sulphide zone in gold-mining operations is usually inevitable. The problem of treating successfully a low-grade sulphide ore by wet metallurgical methods is one of world-wide importance; hence

Mr. Wartenweiler's paper is of more than local interest. In view of the lack of detailed information and the urgent need for knowledge on the subject, the investigation described was commenced several years ago to determine the distribution of gold in the products into which the comminuted ore is classified after amalgamation. In the tests described by Mr. Wartenweiler, flotation was used to separate the pyrite from the gangue. Various oils were tried, the combination finally adopted being one of wood-tar and turpentine, the circuit being acidified by sulphuric acid. A clean separation resulted, as shown by the extremely small amount of sulphur in the resultant tailing. Flotation was adopted as a means of obtaining the data required, not for the purpose of developing a method that would be suitable for the concentration of the ore.

Flotation was carried to an extreme in the first test, in order to ensure a clean, pyrite-free tailing. It is interesting to note that although the concentrate in the slime, amounting to about 5% of the weight of the slime, originally assayed \$22 per ton, it was reduced by ordinary cyanide treatment to \$1.30 per ton. The clean gangue in the slime originally assayed \$0.60, and left the plant containing \$0.12 per ton; it contained 60% of the total gold that was discarded in the slime. In the second series of tests a clean mineral froth was desired, the object being to produce a gangue-free concentrate. In this case the results showed that the concentrate from the slime contained \$32 per ton and represented 2.23% of the total weight; after cyanide treatment it assayed \$1.20 per ton. On the other hand, the slimed gangue with some pyrite, representing 97.77% of the weight, assayed \$0.90 before cyanide treatment and \$0.13 afterward. In this case the silicious portion contained 82.9% of the total gold in the slime residue. In the next series of tests the pulp going to the cyanide plant was analyzed before classification. The gold was found to be distributed as follows: free, 37.5%; in sulphide, 51.4%; in gangue, 11.1%. After classification the sand charge assayed \$2.90; after leaching it assayed \$0.44 per ton. A test on the material before and after cyanide treatment was made to determine, in each case, the proportion of encased gold present; the aqua regia method was used. If an estimation of this character be reliable, it would appear that the cyanide solution penetrates the particles of ore and dissolves the encased gold; for the amount of gold that was soluble in aqua regia in the residue amounted to 93.2%, whereas the amount similarly soluble in the charge amounted to 89.7%. An amalgamation test on the sand showed that 19.4% of the gold was free, an amount that was increased to only 32% after a sample had been ground to pass a 150-mesh screen. It is argued, with logic, that if dissolution by means of aqua regia is analogous to dissolution by cyanide solution, no treatment that necessitates further grinding of the gangue beyond that required by leaching practice is necessary or justified.

An additional interesting fact was disclosed by an analysis of the distribution of the gold in samples that

were taken before and after leaching. Although only 9.7% of the total gold (\$3.08 per ton) in the charge was found associated with the gangue minerals, an analysis of the residue (\$0.50 per ton) showed that the proportion had increased to 26%. In many quarters it is considered impracticable to leach efficiently a charge of fine sand and slime. The detailed figures given in Mr. Wartenweiler's charts in regard to the results obtained by leaching a pyritic ore are of exceptional interest. In the case of a typical charge it was shown that 60.1% would pass a 90-mesh screen. The distribution and extraction of gold from the various sizings are given; valuable information can thus be obtained as to the results of the cyanidation of a mass comprising pyrite and gangue. Thus, in a typical charge of sand of an average assay-value of \$2.91 per ton, it was found that \$2.35 of this was in the pyrite and \$0.56 was in the gangue. The residue averaged \$0.343 per ton, of which the pyrite contained \$0.246, and the gangue, \$0.097. If these two materials were being treated in two different ways, and in different parts of the plant, a comparison could be used to emphasize the absurdity of quoting extraction figures without taking into consideration the original assay-value of the material; for from the pyrite the extraction amounted to nearly 90%, whereas from the gangue it amounted to under 83%. It is interesting to note that the extraction, by leaching, of the gold in the minus 200-mesh concentrate amounted to no less than 94%. This is proof, not only that raw sulphide concentrate can be treated by simple cyanidation, but that a proportion of the finest material can be leached efficiently in a gravity-percolation vat; even the gangue slime (-200 mesh) showed an extraction, during leaching, of over 81%, although the original material assayed only \$1.45 per ton. The results indicate the importance of the fine grinding, previous to leaching, of the sulphide in the sand. This is the concomitant of operating secondary crushers, such as tube-mills, in closed circuit with classifiers. Whether the cones in use on the Witwatersrand are sufficiently delicate to ensure the proper division is open to question. They possess the essential advantage of a capacity that is commensurate with the magnitude of operations; but a field would appear to exist for the introduction of mechanical classifiers of American invention and development, for the efficient treatment of at least a part of the pulp, so that the pyrite might be removed and returned to the tube-mill for re-grinding.

Mr. Wartenweiler's paper has supplied a need for definite information as to the practicability of leaching fine material, as well as in regard to the results to be expected from the treatment of raw pyritic ore. Recently there has been a tendency among metallurgical reformers on the Witwatersrand to revive the contention, of a small but radical group, that gravity leaching should be abolished in favor of fine grinding and filtration by pressure or vacuum, regardless of cost or of loss of gold in the residue. Mr. Wartenweiler's paper offers evidence that such a change would be unjustifiable and stupid. Sliming may be essential elsewhere; all-sliming plants

are operating in many parts of the world with signal success; but neither of these facts can be used logically to justify a change in one of the fundamentals of Rand practice. Extravagant claims are being made as to the saving that may be expected by abolishing amalgamation and adopting all-sliming; but what are the facts as to present losses and costs? Take, for example, the figures of the mines under the management of the Corner House group, which controls nearly half the output of the Witwatersrand; these show that the loss of gold in the residues last year was under 27 cents per ton, after a combined amalgamation-cyanidation treatment. The Government Areas company's residues averaged about 38 cents per ton. It is clear that little or no saving can be effected in this connection without incurring heavy charges for fine grinding and treatment. A typical example of present costs is seen in the case of the Government Areas, whose total expense for sorting, crushing, milling, amalgamating, cyaniding, and disposal of residue was about 67 cents per ton last year; at the Witwatersrand company's plant it was little more than 90 cents per ton. It is inconceivable that appreciable economies would result from the introduction of fine grinding, but rather the reverse. However, the Springs company, acting on the advice of its consulting engineer, Mr. C. R. Davis, is to adopt the 'new metallurgy'. We trust that the data of metallurgical results and costs will continue to be published with the same frankness and in the same detail as heretofore. South Africa has a remarkable record as a producer of gold, thanks to the soundness of the policies of the metallurgical engineers in control of operations. In spite of the serious diminution in the total output of the metal throughout the world, the Transvaal not only has maintained the lead, but, since 1914, has contributed a steadily increasing percentage of the whole. The retention of logical metallurgical methods has been responsible to a considerable extent for this result.

Almost the whole of Mr. Wartenweiler's paper consists of charts. The figures on some of these are illegible, otherwise we might have deduced more that is interesting to our readers. Nevertheless, the information made available is of considerable value; we trust that the experiments will be continued; the publication of such data will serve to encourage the wider application of a simple yet efficient method of treating a low-grade ore, whether it be pyritic or not, and on a scale that will mean increased exploitation and extended interest in gold mining throughout the world. The metallurgical engineers and the mining companies on the Witwatersrand have been generous to a degree in the dissemination of valuable information on the metallurgy of gold; the transactions of the Society, especially during the early days of cyanidation, constitute text-books on the subject; vital data have neither been withheld from publication nor camouflaged. All concerned are to be congratulated on the results, which are reflected in the reports of those companies that have adhered to standard metallurgical practice.

Reverberatory v. Blast-Furnace

The Editor:

Sir—In your issue of September 17 there appears an article by Arthur B. Parsons describing the smelter of the Nevada Con. Copper Co. In the opening paragraphs the author indulges in some generalizations, perhaps not altogether seriously, which tend to spread the mistaken idea that the reverberatory has superseded the time-honored blast-furnace and that the latter is rapidly becoming obsolete. He says:

"If the plant is old enough there is likely to be a blast-furnace department; the probability is that it has been idle for some years, and, moreover, that the furnaces will never run again, although for some strange reason many metallurgists are loath to see these old friends torn down."

Unfortunately, the belief that the copper blast-furnace has served its time is all too common among many who are not in intimate touch with copper smelting, or whose experience and activities have been largely restricted to localities where conditions distinctly favored reverberatory practice. True it is that in certain regions, notably the South-West, the reverberatory predominates, but the reason for this should not be confused. The ascendancy of the reverberatory over the blast-furnace in these districts is the result of wide-spread application of concentration at the expense of direct smelting. Fundamentally, the issue has not been between types of furnaces, but between direct smelting and concentration. The increased production of concentrates has called for more smelting in reverberatories, this type of furnace being especially adapted to the treatment of fine material. In order to compete, the blast-furnace requires a preliminary preparation of such fine material by means of nodulizing, sintering, or briquetting. It is not improbable that improvements in the preparatory process may make of the blast-furnace a dangerous rival to the reverberatory in its own special field, if, indeed, it is not that already. The Braden Copper Co., in designing its new Calumet smelting plant, which will handle a large tonnage of flotation concentrate, decided on nodulizers and blast-furnaces rather than roasters and reverberatories.

Blast-furnaces will occupy a conspicuous place in the equipment of another large copper smelter being built in South America, that of the Cerro de Pasco Co. at Oroya, Peru. In glancing over the important modern copper smelters that have been built in the past eight or ten years, and are therefore comparatively new, one notes

the following having blast-furnace equipment in whole or in part:

Calumet & Arizona.....	Blast-furnaces and reverberatories
United Verde	" " " "
United Verde Extension..	" " " "
Katanga	Blast-furnaces only
Granby, at Anyox.....	" " "
British America Nickel..	" " "

From the foregoing, it is evident that a plant need not be very ancient to be "old enough" to have a blast-furnace department.

A. J. BONE.

Lime in Cyanidation

The Editor:

Sir—In conducting cyanide tests recently we found that somewhat small variations in the quantities of lime used had a marked effect upon the extraction of the gold, and we should like to know if any of your readers have had a similar experience and have been able to attribute the cause. The ore in question assayed as follows: gold, 1.205 oz.; silver, 1 oz. per ton; insoluble, 92.4%; and iron, 2.6%. It was a clean free-milling material with only a small percentage of sulphur combined with the iron. Below we give results of some of the tests:

Lime Lb. per ton	Where used	Crushing Mesh	Hours agi- tated	Tailing Gold, oz	Assay Silver, oz	Density	KCN in solution Lb. per ton
2	In agitator..	65	16	0.06	0.3	3:1	2.9
4	" " " "	65	16	0.11	0.1	3:1	2.9
6	" " " "	65	16	0.71	0.5	3:1	2.9
2	" " " "	65	24	0.55	0.30	3:1	3.0
2	" " " "	65	36	0.5	0.25	3:1	3.0
5	" ball-mill..	65	16	0.57	0.30	1:1	2.0
7 (5 " (2 " agitator)	" " " "	65	16	0.57	0.30	1:1	2.0
5	" ball-mill..	100	16	0.55	0.25	1:1	2.0
7 (5 " (2 " agitator)	" " " "	100	16	0.59	0.20	1:1	2.0
2	" ball-mill..	100	16	0.03	0.20	1:1	2.0
3 (2 " (1 " agitator)	" " " "	100	16	0.17	0.20	1:1	2.0

It will be noted that the condition varied at one time was the quantity of lime and that in the last two tests a difference of only 1 lb. of lime per ton of ore made a difference in the gold extraction of \$2.80 per ton, whereas the silver extraction remained constant. When 5 lb. of lime per ton was used the tailing jumped up to \$11.40.

Under the heading 'Silver Cyanidation at Tonopah', A. H. Jones states* in part as follows:

"In this mill (Millers) at least the lime content is very closely watched, it having been proven not only by

*E. & M. J., April 12, 1913; page 767.

laboratory test but on a working scale, that extraction is very erratic, due to re-precipitation when either too high or too low alkalinity is carried. The lime is maintained between 1 lb. and 1.5 lb. of CaO per ton of solution."

Mr. Jones told us recently that while he satisfied himself that the lime caused re-precipitation, he was unable to find out the reason for this. In our case we cannot follow the re-precipitation theory because the silver extraction remained practically constant whatever amount of lime was used, while the gold extraction alone varied.

Salt Lake City, October 5.

ERNEST GAYFORD.

Panama Canal Toll-Exemption

The Editor:

Sir—In regard to your various recent editorials respecting the exemption of American ships from the tolls of the Panama Canal, I am entirely in agreement with you that the Hay-Pauncefote treaty should not be broken, by putting in force this exemption, without the consent of Great Britain. But I cease to follow you when you advocate the purchase of this consent, for I fail to see that the American people, as a whole, stands to gain anything by the proposed change in the present canal policy. An exemption of American ships from the toll of \$1 per ton will mean a large decrease in the receipts of the Canal; in 1918 (the last year for which I have figures) these were only $6\frac{1}{2}$ millions, or less than $\frac{1}{3}$ of the $20\frac{3}{4}$ millions required for operating expenses and the fixed charges on a capital investment of 400 millions. Of course this decrease must be made up out of the revenue of the Federal government, in addition to the deficit under the prevailing policy, so that the practical question is whether the taxpayers will gain any benefit in return for this increase of their fiscal burden.

In considering the economic effect of the toll exemption and locating the beneficiaries of the taxpayers' loss, the classes of ship-owners, shippers, and consumers naturally suggest themselves as the objects of investigation. The ship-owners fall into two divisions: those of the coastwise and those of the foreign trade. As the coastwise trade is restricted to American bottoms by law, the toll exemption cannot affect them as regards competition with foreign bottoms, for the law allows none, but only as regards their sole competitors, the transcontinental railways. As the exemption saves a dollar per ton in the cost of transport between our Atlantic and Pacific coasts, it is clear that the freight-rates to shippers can be decreased by that amount without affecting marine profits. Whether this decrease in costs benefits shippers or not depends on the preservation of competitive conditions in the coastwise trade; should ship-owners get together and agree to maintain only a semblance of competition, they could then put the dollar of saving into their own coffers. Even should this last mischance be avoided and the whole saving of the toll exemption continue to be absorbed by consumers, in the form of lessened prices for commodities, the economic equity of the whole transaction would be

doubtful for it would mean the subsidy of these consumers residing near the coasts, at the expense of the nation.

In the foreign trade the toll exemption would give American ships a direct advantage in competition with alien bottoms; but here again this would be paid for out of the purse of the Federal taxpayer and would really be nothing but a ship-subsidy in disguised form. If this advantage should ever prove sufficient to run all foreign bottoms out of the Panama route, the income of the canal would be reduced to zero and the whole annual expense for its maintenance would have to be met from the Federal Treasury.

Thus, like a protective tariff, the toll exemption seems, by analysis, to be a proposal where local and special interests are to be benefited at the expense of the general public.

ROBERT BRUCE BRINSMADE.

Ixmiquilpan, Mexico, September 27.

[In the bulletin of the National City Bank we find the following: "It cannot be too strongly urged that the high purpose of limiting and eventually abolishing expenditures upon armaments, and of settling all differences that arise between countries by peaceful means, depends for realization upon mutual good-will, regard for each other's feelings and opinions, and scrupulous regard for treaty obligations." This is well said.—EDITOR.]

Flotation of the Precious Metals

The Editor:

Sir—In regard to Mr. Algernon Del Mar's article in your issue of October 8, although it has been my experience that free or native gold and silver float readily when finely ground, it is hard to understand how the K & K machine makes this recovery possible over other styles of machines.

I have found that a small test-machine will very closely approximate the larger working units if the work is carried on in a practical manner in order that all conditions of treatment as closely as possible approach the working basis. Mr. Del Mar's example that test-machine results of 41% were verified at the start of a 20-ton mill, but that altering conditions, indicated by testing, doubled this extraction, seems to disprove his contention. No doubt the same amount of practical alteration in the experimental work would have shown the same results. At least, it would have been interesting if he had tried duplicating the final accepted treatment with the test-machines. Better work will always be shown in actual mill-practice over test-work following the same procedure, owing to continuity of operation, but it will not show double the recovery. In fact, the betterment should not be great.

Mr. Del Mar's remark that an increase of the amount of froth in the rougher machines tends to reduce the tailing loss seems reasonable. Considering flotation conditions from a physical standpoint and deducing by comparison with older methods of concentration, it seems

reasonable to suppose that building up the froth to a high mineral content and only delivering the concentrate-froth as fast as new mineral is added, will tend to higher extraction, which it does.

As a comparison, if an amalgamation plate is hard or not well dressed and a particle of rusty gold, or carrying a particle of quartz, is passed over, no doubt it will not be caught. But if the plate is well dressed and has a surface of soft amalgam, the particle of rusty gold will readily be held by the bond of the metal-carrying surface.

In the flotation-cell, if the zone of froth is low in mineral content, a partly oxidized sulphide or one associated with a piece of gangue may not carry the oiling condition so as to again drop out. If, however, the froth zone is maintained at a high mineral content, these refractory particles once thrown into the froth zone will be caught and held by the bond effected by this richer froth.

A. H. JONES.

Salt Lake City, October 13.

Surface-Tension in Flotation

The Editor:

Sir—In your issue of October 8 is a discussion by A. C. Halferdahl of my recent paper 'Surface Energy and Adsorption in Flotation'. It is pointed out that the Willard Gibbs adsorption formula holds only for true solutions and that it has not been proved to be true for colloids. Experiments are under way here to ascertain to what extent it does hold for emulsions of flotation-oils and water. The formula was included in my paper with the purpose of emphasizing the relation between surface-tension and adsorption.

Mr. Halferdahl further points out that the surface-tension measurements given were made by a static method and that the measurements by a dynamic method would probably give data of greater interest. Relatively the method used is static, but actually it is also dynamic if proper precautions are not taken in making a measurement of the surface-tension of an emulsion of a flotation-oil in water. The film method also measures a changing tension, which, however, is never very far from the surface-tension at the point of equilibrium between the oil on the surface and the oil in the body of the emulsion.

A method to be of any value in constructing surface-tension concentration curves from which the amount of oil adsorbed by a mineral is determined, must measure the tension of a surface of definite known age and all measurements must be made on surfaces of this same age in order that results may be compared, or it must measure the tension of a surface at a point where equilibrium exists between the oil on the surface and the oil in the body of the emulsion.

Different methods of measuring the surface-tension of emulsions of oil and water give widely different values. Surface-tension concentration curves for a pine-oil in water by three different methods, namely, my method.

the drop-weight method, and the Jaeger capillary-bubble method, are shown in Fig. 1.

Emulsions of many oils in water actually appear to reach a point where the oil adsorbed on the surface is

FIG. 1

in equilibrium with the oil in the bulk of the emulsion. For example, if an emulsion, in a suitable dish, be skimmed with a strip of paraffine paper and its surface-tension be measured immediately by the film method, the surface-tension of the freshly formed surface will be

FIG. 2

fairly high. See Fig. 2. If now the emulsion be circulated* a number of times, and the surface-tension measurements made between circulations, it will be found that the surface-tension falls with each circulation to a point where it seems to remain constant. Further circulations do not effect a further lowering of the surface-tension. If small air-bubbles be blown into the same emulsion for a minute or two, the surface-tension will fall considerably below this constant point, but, on again

*The emulsion is circulated by sucking it up into a 100-cc. pipette and allowing it to discharge into a dish underneath the surface of the emulsion. This method of circulation sets the emulsion in motion without disturbing noticeably the surficial film.

circulating the emulsion, it will go back up to the constant point reached on coming down, but will not go above it.

Surface tension measurements made on emulsions circulated to a constant surface-tension have so far been found to be most reliable. It is surprising how many little factors disturb the surface-tension of an oil-and-water emulsion.

I should like to ask Mr. Halferdahl how he accounts for the inconsistency in the second column of figures in the tabulated data showing static and dynamic surface-tensions for water and mixtures of water and sodium oleate. The surface-tension of water is given as 75 dynes per centimetre and immediately under this the surface-tension of 0.025% and 0.25% sodium-oleate solutions is given as 79 dynes per centimetre, whereas for the same two solutions, by a static method, the surface-tensions are given as 55 and 26 dynes respectively. It is hard to understand how a surface of even only one-thousandth of a second old could have a tension higher than that of water, especially in view of the low values recorded as being obtained by a static method.

Moscow, Idaho, October 11. A. W. FAHRENWALD.

Technical Writing

The Editor:

Sir—Mr. Paul R. Cook, in your issue of October 29, after associating style and literary perfection with a verbosity that tires the reader, suggests that what he terms the practical man "should give the effusions of the writer who possesses literary talent the necessary brevity demanded from an engineering viewpoint; the practical man's message should be subjected to the literary artist, who should be allowed full play whenever he can say as much in as few words".

One notes at first glance the line of demarcation drawn between the so-called practical man and the careful writer. No attitude is more unfair than the one that habitually assumes that the man who makes an effort to use words in their proper sequence and sense is impracticable, visionary, and impotently inactive in so far as the application of ideas is concerned. It has been said that careless writing indicates careless thinking. It is certain that careless thinking leads to inefficiency of action; and inefficiency of action often marks the principal distinction between the so-called practical man and the engineer who co-ordinates effort to logical theory and fundamental principle. Many capable engineers can write well; they are as efficient in practice as they are in theory. Literary ability does not infer unintelligent action.

Mr. Cook puts the cart before the horse; the so-called practical man is undoubtedly the worst offender in so far as verbosity in writing is concerned; such a characteristic marks an elementary acquaintance with literary principles; it persists for a period of time through which we all have to pass, its length depending on our own efforts to improve. The so-called practical man trying to teach

the experienced and careful writer how to condense might well be likened to the burglar endeavoring to reform the minister into whose house he has broken. In any case I foresee other objections to Mr. Cook's plan, that the manuscript of writers with literary talent should be submitted for condensation to the practical man before publication. What type of practical man should be chosen for the task? Suppose, for instance, that an article summarized mining, metallurgical, and economic conditions on a large property in a foreign country; the umpire need be an authority on these subjects, else he might delete what would be of interest and profit to the majority, leaving intact only those parts that appealed to himself and to those in his own sphere of activity; or the article might deal with the validity of Kick's law, with preferential adsorption, or with the Einstein theory. Would Mr. Cook guarantee to find a practical man who could be trusted not to throw a manuscript on such subjects into the waste-basket? Everyone does not appreciate classical music; but this should constitute no valid reason for suggesting that Rachmaninoff, before appearing in public, should submit his program for revision at the hands of the 'musician' in charge of the steam-organ at the local circus; or that the composition of the jazz artist should be revised and corrected by the conductor of the Boston Symphony Orchestra, provided, however, that the result will ensure as much noise without lengthening the score.

Almost all the striving for unmistakable clarity in technical writing results in condensation; proficiency can only be acquired, in the opinion of those who are experienced, by a grinding apprenticeship to an ideal that is never attained. The average editor has at least one difficult task to perform—in connection with the condensation of the literary efforts of the average practical man. Only an insignificant proportion of the corrections in manuscripts are due to a necessity for conforming to style. The acquisition of style is mechanical; effective condensation is an art. The editor's work is concentrated to a large extent on the elimination of verbosity, the re-writing of sentences and phrases so that the concrete is not mixed with or compared to the abstract, the provision of proper punctuation to ensure clarity, and the correction of error. If there be any basis for Mr. Cook's belief that the practical man has the gift of being able to express himself clearly and unmistakably in fewer words than are needed by the experienced writer, then by all means let us have the recipe; for large numbers of students, many editors among them, are spending weary years of labor and care in an effort to gain, by self-discipline and by practice, the proficiency that will enable them to tell their stories, without possibility of misinterpretation, in a few apt and well-chosen sentences. Either literary proficiency is attained only by sustained effort, or, if Mr. Cook be correct, we are witnessing an appalling waste of time on the part of those who know of no other way to become successful writers.

ENGINEER-JOURNALIST.

San Francisco, October 31.

Errors Latent in Mine-Sampling

By Morton Webber

*In basing a mine report on expected output upon sampled areas it should be understood by all concerned that an estimate founded on sampling will still remain an estimate. Irrespective of the experience and care exhibited in the work, the valuing engineer will undertake too much if he assumes that such data embody a statement of fact. The fallibility of an approximation cannot be eliminated, although in cases it may be modified to meet practical requirements.

There is a latent error varying with the mineral nature of ore deposits that it is impossible under practical conditions to control by extreme uniformity in cutting samples and their nearness to each other. This error usually indicates a higher metallic content than shown throughout an adequate period of actual ore-treatment, affording data of results in mill-yield, plus residual contents. In the South African banket, the mill-yield plus tailing-content is from 6 to 15% short of the average indicated by sampling. In the premier lead mines of Australia the discrepancy is at least 10%. The results from four well-known gold mines show an unaccounted difference of 12%. These mines are situated respectively in Mexico, Colorado, Australia, and India.

In the valuation of a mine, conditions will generally fall under one or more of five classes. After tabulating these, as is done below, I shall endeavor to discuss each in turn. Under practical conditions many of these classes will merge and shade into each other in the same mine; they are separated here largely to facilitate explanation.

(1) Where the average metal-value is mechanically reduced, but where the unaccounted metal may be subsequently recovered.

(2) Where there exists an unrecoverable loss.

(3) Where sampling indicates a fictitiously high value.

(4) Where sampling gives an incorrect subnormal value, conclusive proof being afforded by subsequent operations.

(5) Where sampling is of no use.

(1) In narrow veins where the breaking of waste is necessary, the ore going to the mill will be reduced in grade. Even if sorting is carefully done, it is impossible to keep all the waste out of the mill, especially if the enclosing walls are soft, yielding more or less fine material. In a narrow vein it is customary to allow for this, but my experience is that such an allowance is generally insufficient. Even in veins of normal width it is usually impossible to break ore without the inclusion of some waste. In such a case the discrepancy in metallic con-

tent is likely to be considerable, owing to the fact that no hand-sorting may be employed. This discrepancy will largely adjust itself when the mine or slope is worked out, as the decreased value per ton is compensated by the greater tonnage crushed; but the valuing engineer, if wise, when computing his factor of loss, will largely disregard this; as it will be difficult to explain to those not versed in valuation that the mill discrepancy will adjust itself by a greater tonnage crushed.

(2) In mines in which filling is necessary, and also in cases of underground sorting, there is always a loss in the waste, even where boards are used. This may cause a loss of tonnage rather than of value per ton—possibly a combination of both. In either case it is a loss of marketable contents that the mine-valuer should be careful to deduct from his estimate.

(3) Where the metallic contents of ores are in sulphide form the sulphides are frequently more friable than the gangue. In consequence, the samples will contain an abnormal proportion of high-grade 'metallics'. Discrepancies of this kind are more usual in copper and other base-metal mines, but in the case of gold and silver ores, in which the metal may be enclosed in a friable sulphide, this error should be very carefully considered, as it may result in an estimation out of all proportion to subsequent results.

I quote an example from my own experience: The lode was a fault-vein in rhyolite. There was a vertical displacement of about 32 ft. resulting in brecciation, the fracturing having occurred when the rhyolite was comparatively cold. The auriferous solutions, which were post-fault, formed the cementing material. The fragments of rhyolite were almost entirely undigested. A sampling-error of about 17% existed.† The angular fragments contained no gold, and the cementing material, which was 'high-grade', was in process of rapid decomposition and when sampled broke down out of proportion to its relation in the ore.

This is an excellent example of a latent sampling-error as distinct from a mechanical error. A simple example of the latter is the sampling of a width narrower than is subsequently mined. This error is not latent, for it is due either to faulty judgment by the valuing engineer or lack of co-ordination in his views and the operations of the mine. The latent error is inherent in each sample without relation to care or judgment.

(4) Where there are two sulphides in the same ore, one hard and dense and the other soft and friable, the latter will break more easily in sampling, and therefore will be abnormally represented in the valuation. If the

*This article appeared in the 'Mining Magazine' of February 1915, and is re-printed now by request of several engineers. The author has taken the opportunity to add some examples from experience.

†As disclosed by milling blocks of ore and comparing mill-yield plus tailing-loss with hand-sampling.

major richness is in the hard sulphide the inference is likely to be unfair to the property.

Some years ago I examined a copper mine in which the ore was chalcopyrite. After carefully sampling the ore exposed, which I estimated as a mass 550 ft. long by 8 ft. wide and 300 ft. deep (the bottom of the mine at that time), my average was $4\frac{1}{2}\%$ copper. My estimate of tonnage from this block was 440 tons per horizontal foot. Since that time this ore has been stoped. The tonnage actually mined has aggregated 130,000 tons, or 430 tons per horizontal foot. Such a close estimate clearly proves that the mass that was removed was practically the same as was estimated in my examination. It is evident that the inclusion of waste and pillars did not vitiate the comparison. The subsequent treatment of the ore proved by estimate of $4\frac{1}{2}\%$ copper to have been about $\frac{1}{2}\%$ low; or an error of over 11% on the total copper-value. It is my opinion that the unavoidable breaking down of an excessive proportion of the friable ore of lower grade was responsible for the error. For this there is no preventive under practical conditions. It is only possible to remedy the discrepancy by the addition or subtraction of a factor as the outcome of experience. A discussion of the shortening of the distance between sample-cuts, so often the last resort of an engineer to promote accuracy in difficult cases, has no bearing on the matter.

(5) There are mines in which the valuable minerals occur in bunches. Under such conditions no confidence can be placed in an assay-map, even though an unusually close sampling interval may have been adopted. A level may pierce a certain number of enrichments, which would be represented on the sampling record. Had the horizon of the level, however, been 30 ft. higher or lower, the number of enrichments pierced might be out of all proportion to the true average. In a mine of this type an attempt to estimate the contents of a block of ore would be absurd. The nature of the ore occurrence would demand a veritable network of levels and rises so close together that all hope of profitable operations would be killed by the cost of development. Many mines exist in which an assay-plan would show the majority of samples to be unprofitable, yet the subsequent exploitation has afforded conclusive proof to the contrary. This does not refer only to precious-metal mines. The base-metal mines of Missouri and the copper mines of Lake Superior are analogous. Under such conditions the only reliable valuation would be based upon an authentic record of the past yield, checked by competently selected representative shipments of the remaining ore.

All this goes to show the great care that should be exercised by an engineer in forming an opinion concerning the accuracy of another engineer's examination. There are many instances where an engineer has attempted to check a former examination by re-sampling a number of cuts. I am aware of several cases in which an engineer has been employed to check the work of another, and because he could not check a selected number of sample-cuts he condemned the mine; and without

reason cast a slur on the careful work of a fellow engineer.

Some time ago I was employed to report on a gold-silver mine. It had been examined not long before my arrival by another engineer acting on behalf of the vendor. It was necessary to sample the floor of part of the lowest level for a distance of 200 ft. The ore had been stoped above. There was about 18 in. of broken decomposed material in the level-bottom. The former engineer had sunk pits about 2 ft. deep, at intervals of every 10 ft. As the blasting and cutting of a fresh series of pits would entail considerable time, I decided to re-sample the old pits, after carefully cleaning and blasting a new surface. In both cases we sampled over 5 ft., the width between timbers. I here give the results of our sampling. The former engineer's results I tabulate with mine, for each of the 20 pits. My results are marked W, whereas those of the other man are marked X.

Number of pit	Sampling by W	Sampling by X	Number of pit	Sampling by W	Sampling by X
1	\$11.25	\$15.50	11	\$30.28	\$25.50
2	8.56	10.75	12	35.50	25.18
3	15.75	12.15	13	50.00	45.12
4	15.52	14.25	14	18.23	23.18
5	9.25	5.25	15	20.25	18.75
6	26.50	17.20	16	13.16	15.50
7	5.30	10.80	17	12.76	18.20
8	26.20	30.83	18	8.18	10.50
9	18.40	25.25	19	20.50	18.00
10	15.30	18.15	20	5.15	7.75

It is at once noticeable that in no instance are our results even reasonably close. The samples individually, at best, only demonstrate pay-ore; this is all they seem to have in common. In checking a few selected pits, our results would have indicated a wide discrepancy; this might have thrown discredit on the entire work of the other engineer. That we are both equally correct is indicated by the average of our total results, namely, \$18.30 and \$18.29; both samplings were over a width of 5 ft.; these are facts that cannot be overlooked. They prove that, where sulphides are sampled, detailed comparisons are unreliable; they demonstrate that a fundamental factor in the use of sampling data is the law of averages; they show that decreasing the interval and taking more samples is not the remedy, because the error is latent in each sample. Had I sunk fresh pits at 5-ft. intervals and re-sampled my own work I am satisfied that the results would have varied just as much; certainly the final result could not be closer. In checking and comparing the sampling of the same mine by different engineers the proper use of averaging should be confined as far as possible to the comparing of underground areas. The comparison of samples, each to each, is unimportant.

In my judgment, in analogous cases, if it be impossible to get individual samples to check, there is a strong probability that there will be a considerable discrepancy between the sampling results and the subsequent mill-feed. Such has been my experience. In the case above, although it might seem that the other engineer and myself could be proud of our ability as mine-samplers, I really think that we only succeeded in making the same error. The discrepancy between mine-sampling and mill-

ore in this case would probably not have been less than 10%.

As an example on the borderland between latent and mechanical errors I may refer to a large gold mine in Nevada. It illustrates the danger of underestimating the native intelligence of the 'old-timer' in the search for ore. It also may stimulate the sixth sense of the valuing engineer in detecting a 'joker'.

The mine was developed to a stage where a large tonnage of low-grade ore was exposed; on the strength of which a large mill had been erected. Shortly after the completion of the mill the owners became financially embarrassed through other enterprises, and they decided to sell the mine; whereupon the property was purchased by a large company. The engineers of the buyer estimated a large tonnage of low-grade ore that, in view of its magnitude, was expected to be profitable. Shortly after milling commenced the mill-feed dropped to the cost line and all attempts to operate at a profit proved futile. A search for the cause disclosed these facts:

The property had been developed by the 'old-timers' along one side of the deposit, the width of the vein being several times that of the drift. Cross-cuts had been driven to the other wall, in order to ascertain the full width. The sampling of the cross-cuts indicated that all the vein was profitable ore. An investigation showed that the gold of the large vein was contained in small 'willow' veins within, and at right angles to, the large vein. When the faces were fresh and clean the old-timers had observed points of recurring congestion of the willow veins. At these points the cross-cuts were driven. When later the mine was sampled the openings had become covered with dirt; this prevented the engineers for the purchaser from detecting the peculiar character of the deposit, and they assumed that the sampling of the cross-cuts would represent the mass as mined. The milling of a few blocks of the orebody showed that the sampling was 50% too high; and a heavy loss had to be faced, for the mine had been sold for cash.

Constructive criticism of the work of these engineers is pertinent in order to avoid a repetition of the mistake. Experience is largely built on mistakes.

The cross-cuts were not driven at regular intervals. An examining engineer should always be careful to investigate the reason for placing cross-cuts at irregular intervals if the sampling of the cross-cuts is to form the basis of an estimate of the ore available. It is better business to offer a larger sum for a mine in order to get additional time to obtain complete information, by extending cross-cuts into untested blocks of ground, than to buy the mine for cash. My experience has been that if a vendor will not give a reasonable extension of time when offered, say, 10 to 20% more than he is willing to take for cash, then it is better to profit by the vendor's inside knowledge of his own mine and to drop the business. Reputations are easier lost than made.

I would also emphasize the other feature suggested by this example, namely, the covering of evidence that was obvious to the old-timer when the faces were fresh. Dirt

covers underground surfaces rapidly. Many mines would look very different if some inexpensive means could be devised to give their entire exposures underground a good washing, so that the ore-occurrence could be studied and the rock-structure could be easily observed. If their 'black but comely' appearance were removed, some unfortunate experiences with such mines would be avoided.

It is impossible to tabulate the percentage of error under the relative heads discussed and to apply the results in specific cases. The engineer must use his own judgment in the examination of a mine. What has been written is intended to enable him to form a conclusion of sound premises based on given conditions. In most cases sampling will over-estimate operating results; the amount of error will vary from 5 to 25%. In the majority of cases the error is about 12%. Examples giving sub-normal results do exist, but they are in the minority; and before any improvement on the mine-sampling can be anticipated these favorable facts must be thoroughly understood.

DURING an address on the relation of economic geology to the general principles of geology, before the Society of Economic Geologists, R. A. F. Penrose, Jr., stated that many geologic phenomena have been utilized by mankind both long before and long after their scientific significance was known. Thus prehistoric man often lived in caves of splendid proportions without a conception of how these abodes were formed, until geology, many centuries or even thousands of centuries later, demonstrated their origin. The discovery of flowing artesian water in Artois, France, was made many centuries before its geologic cause was discovered; but, when this was found, the discovery of similar wells was vastly increased. The discovery of oil for the first time in a boring was made in Pennsylvania in 1859, and was a wild venture, unguided by scientific conceptions; but, step by step, economic geology came to the rescue, and finally, some 30 years later, Dr. J. C. White developed his theory that oil was to be found where certain structural features of the rocks favored its accumulation. From that time the search became an intelligent exploration. Thus many geologic phenomena have been used for practical purposes by man before geology has made their causes known. On the other hand, the causes of many geologic phenomena have been discovered long before their usefulness has become apparent; but in years or perhaps generations later this knowledge has become of value to the human race. A striking instance of this is the careful petrographic study of rocks which has been developed in recent years and which at first was apparently purely unpractical. It has now, however, become of great importance in deciding the resistance of different rocks to atmospheric and other conditions. If such knowledge had been available in bygone ages, many stone structures might still be standing, because they would have been built of more durable rocks; many of our highways, quickly torn by the automobile, might have been made durable for ages.

The Uranium and Radium of Katanga

By M. H. Buttgenbach

*In 1913, in the course of development work done by the Belgian company known as the Union Minière du Haut Katanga at the Luswishi copper mine, situated a few kilometres north of Elisabethville, an important discovery was made. Several small veins, at the most 30 centimetres wide, filled with a mineral of unusual appearance, were exposed. The vein-filling consisted chiefly of uranium oxide.

Since then I have examined specimens of this ore, which occurs in the form of compact lumps; it has a density of 5.08; it scratches calcite; in color it is orange-red, and it includes grains of a black mineral several millimetres thick. On the outside these lumps have the appearance of being the result of the alteration of cubic crystals that have been agglomerated; however, they are covered with a coating the color of which shades from yellow to yellowish green; this coating extends occasionally into the minute cracks that traverse the orange-colored lumps.

By means of photographic tests I ascertained that each of the three substances—the black grains, the orange lumps, and the green coating—were radio-active, but with an intensity varying in the order indicated. The black grains produced an impression on the plate in a few hours only, whereas the green coating required an exposure of nearly two days. From this same ore I was able to obtain several decigrammes of barium chloride distinctly radio-active.

The complete analysis of an orange-red lump, as made by M. C. Gillet, on a specimen that had been carefully selected, gave the following results:

Uranium	68.203%
Lime	10.360
Lead oxide	6.388
Barium oxide	1.655
Copper oxide	0.145
Silica	2.804
Combined water	9.449
	<hr/>
	99.004%

The oxide of uranium indicated is the dioxide, UO_2 , calculated after precipitation of all the uranium as sodium uranate, but it is probable that the uranium occurs in the ore partly as UO_2 , partly as UO_3 .

In density, color, hardness, and composition this mineral resembles 'gummite', which may be considered as a product of the decomposition from pitchblende, and to which F. Olthoff gives the formula

The analyses given for this mineral in textbooks moreover show that its composition is very variable.

*Translated by the Editor from 'Le Mouvement Géographique' of July 2, 1921.

The green part that covers the gummite has a composition even more complex. In general, the content in silica increases and in uranium decreases. The following result of an analysis, likewise made by Mr. Gillet, gives an idea of its composition, but I ought to add that it was not possible to collect as pure a sample as in the case of the gummite.

Silica	15.266
Uranium	45.515
Lime	6.340
Lead oxide	3.897
Copper oxide	1.386
Cobalt oxide	2.500
Nickel oxide	1.520
Oxides of iron, aluminum, and manganese	8.480
Combined water	12.103
	<hr/>
	97.007

This green matter frequently has a lustre that is greasy or waxy, but occasionally it turns into minute acicular crystals. Under the microscope, these needles, which attain at the most a thickness of five hundredths of a millimetre, show a lovely yellow tint, without appreciable dichroism. These needles give the colors of polarization below the blue of the second order; they become less bright longitudinally, following the optical axis; a negative section is perpendicular to the face of the plane surface, which appears to be a cleavage plane. Another cleavage, less easy, appears to make an angle of 87° with the direction of length. The crystals are sometimes terminated by one face, not in agreement with the second cleavage, and make an angle of 54° with the line of length.

I consider this mineral to be composed of 'uranotil', the chemical composition of which, according to Genth, can be expressed by the formula

The Luswishi ore then is composed chiefly of gummite, resulting from the alteration of pitchblende, of which there still remains intact in the lumps some portions in the shape of black grains. The gummite itself has yielded uranotil.

It is conceded nowadays that the ores of uranium contain radium in the proportion of 320 milligrammes of metallic uranium per ton. One ton of the Luswishi ore, at 60.2% of uranium dioxide, therefore would contain 601.17 kilogrammes of uranium and 192 milligrammes of radium. It is true it seems that the proportion indicated above of uranium to radium is not exact except for the primary minerals of uranium and that the proportion diminishes in the minerals resulting from their decomposition. However that may be, the Luswishi ore is extremely radio-active, as proved by the experiments I made with the electroscope. One knows that the radio-

active power is measured by the velocity of discharge of that instrument when under the influence of the mineral reduced to a powder and compared with that of the black oxide of uranium, UO_2 . The mean of six trials showed a power of 2.969, the standard being based upon 0.202 of uranium oxide.

The investigations conducted at the Luswishi deposit were interrupted by the War. However, in 1915, a similar discovery was made in a deposit at Shikolowe (Kasolo), situated south of Kambove. Whereas at Luswishi the veins containing the uraniferous ore are very narrow, at Shikolowe the vein assumes the shape of a rosary, with swellings and pinchings. The enclosing beds, with a strike N.70 E., are composed of the rocks usual to the copper deposits of that region: talcose schists, dolomites, breccias. These beds are much disordered and cut by faults, and there are found impregnations of ores containing copper, cobalt, and manganese. Generally the beds dip northward, whereas the uraniferous veins dip to the south, at an angle ranging from 20° to 45° . In the swellings the vein is almost entirely filled with an orange-red mineral which is referred to gummite; in the pinchings the gummite gives place to a mineral in micaceous flakes which may be chalcocite or autumite. But, not having as yet received specimens of this deposit, I cannot say what is to be thought of this phosphatic ore, the like of which has not been found at Luswishi.

The known deposits of uranium and radium may be classified as follows:

1. Deposits of pitchblende (uranate of uranil) in the form of veins with a complex filling.
2. Deposits of autumite (hydrous phosphate of uranium and lime) filling crevices in pegmatite.
3. Deposits of carnotite (vanadate of uranium, potash, and lime) consisting of sandstone impregnated with this mineral.
4. Deposits of betafite (niobo-titanate of uranium) consisting of concentrations in pegmatite.

It is very probable that the uraniferous and radio-ferous orebodies of Katanga ought to be referred to the first type. The prospecting operations are being continued. It is unnecessary to direct attention to the importance this discovery may acquire, for the introduction into Belgium of a new chemical industry enabling, by the aid of ores coming from the colonies, the obtaining of a product the use of which is limited by its scarceness, and of which among others medicine, experimental as well as clinical, demands without ceasing larger quantities. ▲

Russian Metallurgy Under Soviet Rule

*The largest pre-war copper production in Russia was at the Kishtim works in the Urals, where in 1914 more than 32,258 long tons (2,000,000 poods) was produced. This declined about 20% during the first years of the

War, and has now practically ceased, only a few small works being in operation. Although deposits of zinc ore are found all over Russia, the production of the metal in 1914 did not exceed 1129 tons, but works with a productive capacity of 48,387 tons per annum were begun in 1915 and, although not finished, produced 29,032 tons of metallic zinc by the end of 1917. The revolution arrested the completion of the works, but it is believed that, could they be started again, not only the home market but also foreign demand might be satisfied, especially as many of the Siberian deposits contain sufficient silver and gold to reduce the cost of production below that of the United States or Germany. Lead-ore mining was begun in Russia in 1701 and during the 18th century production steadily increased; it began to decline during the 19th century owing to the difficulties encountered in working the complex ores found in Siberia. In 1916, however, works for the production of more than 16,000 tons annually were erected at the Ekibastus mines, and mining was commenced in the Kirghiz steppes, the Caucasus, and the Urals. The completion of the South Siberian railway should develop a country rich in lead ores and with good coal deposits, of which those at Ekibastus and Kuz-Chikinsk are already worked. The Russo-Asiatic Consolidated Co., on completion of its projects, should be able to produce annually metals and minerals (including coal) to the value of over £10,000,000. In 1913 Russia produced about 56% of the total world's output of manganese but only 5% of its pig-iron. The large surplus of manganese ore supplied 65% of the total German requirements; and as in future Germany will have to rely entirely on Russian supplies, the future of the industry seems assured. The fuel crisis is the real cause of the delay in reconstruction, as the following figures for fuel consumption show:

Year	Consumption of coal, long tons	Consumption of wood, 1000 cu. ft.
1916	24,552,758	5,837,517
1917	4,474,778
1918	3,257,471
1919	5,487,435	2,151,165
1920	5,080,351

(1 ton = 62 poods; 1 cu. sagene = 313 cu. ft.)

The average monthly production of petroleum in 1920 was only 40% of that for 1913, and is still decreasing, being now inadequate to meet the home demand. The output of pig-iron has fallen from 4,651,581 long tons in 1913 to 44,113 tons during the first half of 1920; 520,000 workers are now employed. Many works have been closed, but the Government is running 21 so-called storm factories (employing 65,678 workers), whose duty is to reconstruct the disorganized transport system by intensified production and to form a nucleus for the revival of industry. These factories are given first call on supplies, but have been hampered by labor difficulties, especially absenteeism, due to difficulty in getting food. The Communists have recognized the insolvency of their original system and now seek to introduce individual management, to create a labor army, and to bind the men to the works. Unfortunately in applying these principles the works have been overstaffed with officials, of whom there are two to every three workers.

The Mining Industry of Mexico: A Historical Sketch

Part II

By Robert G. Cleland

(1810-1910)

EFFECTS OF THE REVOLUTION. At the close of the Colonial Period, the mining industry of Mexico was at its height. The average annual yield of gold and silver was between \$20,000,000 and \$24,000,000. The price of quicksilver and the duties on supplies had been reduced considerably. A Mining Bank under royal control provided funds at reasonable rates for the development and rehabilitation of desirable properties; a school of mines promised to remedy the lack of scientific knowledge and technical skill under which the industry labored. But in the midst of this prosperity came the War of Independence, with its accompaniment of brigandage and crime. At the close of the ten years of revolution the industry was almost in ruins. Its demoralized condition was thus described by H. G. Ward, British chargé d'affaires in Mexico from 1825 to 1827:

"The Civil War entirely destroyed the chain of communication between the highest and lowest classes of mining speculators. In many districts the 'haciendas' of the 'rescatadores' were ruined, as were the machinery and works of the mines themselves. In others, water was allowed to accumulate to an immense extent, in consequence of the suspension of the usual labors; while in all, the merchants who had before supplied funds for carrying on the different operations, withdrew their capital as soon as the intercourse between the seat of government and the provinces was interrupted. In the years 1811 and 1812, the agricultural produce of the country likewise decreased so rapidly that it became difficult to procure the means of subsistence. The mining towns were surrounded by insurgent parties, which occupied the whole of the open country, and rendered it impossible either to receive supplies or to make remittances, without the protection of a large escort; while the exactions of the officers, by whom these escorts were commanded (exactions which were reduced to a system, and in which the viceroy himself largely participated), doubled the price of quicksilver, and every other article consumed in the mines; and thus reduced the value of silver to the miner so much that the marc did not repay the cost of extraction, even with the richest ores. The poor ores were allowed to accumulate untouched.

"This was the real evil of the Revolution. It was not the destruction of the 'material' of the mines, however severe the loss, that could have prevented them from recovering from the shock, as soon as the first fury of the civil war had subsided; but the want of confidence, and the constant risk to which capital was exposed—which from being in so tangible a shape, was an object of attraction to all parties—led to the gradual dissolution of the system, which it had required three centuries to bring to the state of perfection in which it existed at the commencement of the War of Independence."

The physical injury to which Ward referred was

more serious than one gathers from his description. Most of the mines had filled with water, the timbering in others had decayed, causing them to cave; even those that had remained in operation had suffered fully as much damage as the others from 'high-graders', or *buscones*, who robbed the pillars and veins of the more valuable ore, thus letting the roof fall in or leaving behind mineral of so low a grade that the mine could not be worked with profit. The industry had also suffered from the disruption of its labor force, for the mine employees had been forced to quit their occupation and join with one or the other faction. As a result, the annual production decreased from 20 or 24 millions to about 4 millions. The need for re-creating the industry, both to secure public revenue and to revive business generally throughout the country, was acute. But Mexico had no capital with which to do this, for the original mine-owners, mostly Spaniards, had been killed or driven from the country; the old system, under which operations were financed by the merchants and ore-buyers, or *rescatadores*, was broken up by the revolution.

ENTRANCE OF FOREIGN COMPANIES. Capital had to be secured if the mines were to be re-opened; the foreigner was invited, both by the agents of mine-owners, who went to England, France, and the United States for the purpose, and by Mexican government officials, among whom the most notable was Lucius Alaman. The general mining laws of Spain made no distinction between alien and citizen; but the law of the Indies forbade the presence of strangers in the colonies, so that the mines of Mexico had been closed to foreigners throughout the Colonial Period. In 1823, however, a decree was passed permitting foreigners to acquire shares in mining properties. This was followed by the organization of a number of foreign companies to exploit the abandoned Mexican mines. Seven of these companies were financed by English investors. One of them, the Anglo-Mexican Co., capitalized at \$5,000,000, in three years spent over \$4,000,000 in the operation of its 36 mines, some of which were among the most productive of the Spanish period. Another, the United Mexican Mining Association, capitalized at \$6,000,000, owned mines in Guanajuato, Zacatecas, Chihuahua, Oaxaca, Hidalgo, Michoacan, Mexico, and Guerrero; it also established iron works in Durango, and operated the mint in Mexico City. The Tlalpujahua Co., with a directorate partly English and partly French, was capitalized at \$2,000,000; it owned 86 mines, of which it operated 39, and employed over 2000 men. The remaining English companies, among

which was the Real del Monte, operated on a less extensive scale in various parts of the Republic. German capitalists organized the Eberfeldt Mining Co. and secured properties in Hidalgo, Mexico, and Michoacan.

Investors in the United States also became interested in the Mexican fields. Joel R. Poinsett, the first American Minister to Mexico, was alarmed at the growth of English influence in the country and sought to counteract it by the organization in the United States of mining companies similar to those of British origin. One of these American companies was incorporated in Baltimore; the other, the United States Mexico Co., secured a charter from the legislature of New York, and obtained possession under lease of mines in Tamascaltepec, among which was the Cinco Señores, about a hundred miles from Mexico City.

For a number of years, on the other hand, the British companies carried on extensive operations and aroused an excitement among the investing public comparable to that of the South Sea Bubble a century before. Fabulous reports were spread as to the riches of the Mexican mines. Baron Von Humboldt, whose 'Kingdom of New Spain' appeared in 1811, was drawn upon for statistics and alluring descriptions, thus doubtless proving the unwitting cause of many an English investor's downfall. The directors of the British companies were as little acquainted with the true situation in Mexico as were the stockholders. Without taking into account the real ability of their Spanish predecessors they tried to supplant everything native by importations from Europe. Huge steam-pumps and other machinery were shipped from England, and transported over specially constructed roads to the mines of El Oro, Guanajuato, and even as far as San Luis Potosí, at enormous labor and almost prohibitive expense. Adits and underground workings costing thousands of pounds were undertaken without careful estimates of the results to be achieved by their construction. Cornwall was deprived of half its population to furnish workmen in place of the skilled Mexican miners. Follies too numerous to mention absorbed the capital of the shareholders, together with the large quantities of bullion that some of the mines produced.

Other factors, besides unwise management, contributed to the failure of these early foreign ventures. The disturbed condition of the country and the difficulties of transportation furnished unforeseen drains upon the capital advanced; the condition of the mines themselves was such as to make large profits somewhat doubtful. Under Spanish ownership most of these had been worked to such a depth that, even with machinery, the cost of raising the ore to the surface and of keeping the workings free from water consumed a large proportion of the returns, and in numerous cases absorbed much more than the mine was capable of producing. Furthermore, the Mexicans took advantage of the ignorance of the foreigners when negotiating the *avios* or leases under which the properties were held. As a result of these unfavorable circumstances, most of the British companies sus-

pended operations before 1835 with serious loss to the shareholders. The few that remained continued to operate with ever increasing deficits, until all but one or two were forced to withdraw to escape bankruptcy. The first experiment of foreign exploitation of Mexican mines thus ended in failure.

OBSTACLES AND HANDICAPS. After the disappearance of foreign companies the mining industry settled down to a period of quiet. Production averaged about \$12,000,000 per year, most of which came from a few large bonanzas. After 1850 there was some increase of this amount, but the stormy days of French intervention and the revolutionary period succeeding brought the industry to the verge of ruin. In 1877 the combined output of gold and silver amounted to only \$13,000,000. The northern border States—Sonora, Chihuahua, and Coahuila—were undergoing a reign of terror at the hands of the Comanche and Apache Indians, who carried on their depredations without any opposition from the Government. Operations in nearly all the mines of Coahuila had been suspended, and the State was reduced to a wilderness. Chihuahua had been brought to the verge of ruin and was partly abandoned. In Sonora, "the land of romance, the land of tragedy, the dream-land of the filibuster", not more than 14 mines were being worked at full capacity.

In addition to Indian depredations, the country was over-run by bands of outlaws or lawless soldiery. Shipments of bullion could be made only under heavy guard; the rate of exchange with the interior was high, running as much as 10% between Mexico City and Chihuahua; travel in the interior was dangerous; mining companies were frequently robbed of supplies and bullion, or forced to contribute to the support of military bands.

In addition to these difficulties others no less serious but of a different character retarded mining development. Taxes had constituted a serious handicap to the industry, even during the Spanish period, and these had been still further increased by the Republican government; in 1825 the industry paid at least 18% to the national treasury. By 1868 these taxes had been raised to between 24 and 26%, divided as follows: assay dues, 6½%; coinage dues, 4½%; circulation tax, 2½%; and export duties, 7½%. State taxes made up the remainder. Under such a tax, miners who found no means of smuggling their product out of the country or otherwise evading the government charges could scarcely operate at a profit.

Another drawback to the business was the lack of transportation throughout the country. Ore, bullion, and supplies had to be carried in rude carts, on mule-back, or by Indians over miserable highways or mountain trails. These methods, which are still in common practice in Mexico where railroads are lacking, were expensive and inadequate. Even with the use of carts it cost \$20 per ton to transport supplies from Mexico City to Pachuca, a distance of 70 miles, and over \$100 per ton from Vera Cruz. Distribution of food could not be equalized throughout the country; so that when corn

was selling for 75 centavos per fanega* in one section, a mining camp 200 miles distant might well pay P9 for the same amount. Large machinery could not be brought even to those mines lying close to the capital except at enormous cost: to transport such heavy material to districts lying away from well-established roads was impossible. Ores could not be shipped from the mine except at heavy cost, and consequently if too low-grade to be treated on the spot were of no value.

Another serious difficulty confronted by the industry was the lack of capital necessary to develop the mines, to install adequate machinery, and to erect modern smelting and refining works. Such sources of supply as existed under Spanish rule had come to an end with the revolution or with the disappearance of the foreign companies before the middle of the century. Mexico was consequently compelled to rely almost wholly upon her own resources, which were entirely inadequate to meet the demands of the business. Mining had therefore been reduced to a hand-to-mouth affair, conducted throughout the country, except in the case of bonanza properties, in much the same way in which General Lew Wallace found it in Chihuahua in 1867.

"Santa Eulalia", he wrote, "really ceased to be worked in any magnitude when the Spaniards were driven out of Mexico. In different ways the mines fell to owners who had little capital and still less energy. As miners, the Mexicans are, in some respects, without superiors; they can tell at a glance the quality of ore, and in the mere manipulation they excel; but when extensive management is required of them they utterly fail. When his mine is bonanza the Mexican owner loses his head; he takes no care of his money, is open-handed as a child, and acts as if the treasure was inexhaustible. Consequently, when the present 'pocket' runs out he has nothing wherewith to renew operations. As a rule, Mexicans, however intelligent and educated, have no genius for machinery. They blow, crush, and drill as their fathers before them did. For transportation of ore they prefer a train of donkeys to a train of cars, and steam-engines are incomprehensible to them. Moreover, unlike Yankees, Mexicans are not associative for purposes of business; in fact, they know absolutely nothing of association as an element in great enterprise. As for the individuals, there is but one gentleman in Chihuahua rich enough to work Santa Eulalia as it deserves, and he is a merchant, and, strange to say, bitterly opposed to mining, although his fortune came from that source. If it depended upon the present owners, work in the mines would altogether cease. They derive aid, however, from others. Thus Señor Mateas has his backers in the City, who advance him limited sums of money, which he uses to pay his workmen and meet current expenses; when he brings the product of his labor to market and sells it, he not only returns the principal of the loan, but also pays his accommodating friend two-thirds of the profit. Such a system, together with the loans pursued, will keep that excellent gentleman poor though he owned all the mines in Mexico and lived a thousand years. As for foreigners, Frenchmen, Englishmen, and Americans have often sought to obtain the control of the mine of Santa Eulalia, but in vain."

In addition to this lack of capital the confusion in laws resulting from the constitutional grant of 1857, under which each State could legislate on mining matters, also hampered the development of mineral resources.

Under the Mexican system of mining and metallurgy, moreover, the mines were becoming increasingly difficult to work. In the older regions some shafts, like that of the Valenciana, were down nearly 2000 ft. To bring the ore to the surface from such depths and keep the lower workings clear of water were problems too great for the Mexicans to solve; districts once famous for their riches, like that of Guanajuato, were gradually abandoned. High-grade ore, relatively easy to obtain, alone was profitable; of the baser metals, such as iron, lead, and zinc, there was no production in commercial quantities. Copper was mined almost entirely for use in the amalgamation of silver. Coal was not produced.

REVIVAL UNDER DIAZ. Such in general was the situation when Diaz became president. During the first years of his administration the northern States were freed from the menace of the Apaches and Comanches as a result of the combined activities of Mexican and United States troops. Domestic peace was also established, by what means it is not the function of this article to say. Life and property, however, became so safe throughout the Republic, with the exception of the Yaqui region in Sonora, that it might be said of Diaz as it was said of one of the early kings of England, "a man with his wallet full of gold might walk seathless from sea to sea". Prospectors and mining engineers found it possible to penetrate remote mountain regions without danger to life or fear of robbery. Mining camps were established in isolated regions, and suffered no harm from outlawry or depredations. Companies were also able to transport their bullion under a small guard, usually of native Mexicans, without danger of loss. The Batopilas company, for instance, though its mine is in the heart of the Sierra Madre mountains in south-western Chihuahua, sent out over thirty million ounces of silver from 1887 to 1910 without the loss of a single bar. The shipments were made by pack-train under native guard over a mountain trail. Ten days or more was required for each trip.

In addition to establishing security for life and property, President Diaz encouraged the building of railroads and the development of transportation facilities. Nothing had a more stimulating influence upon mining development in Mexico than this. Regions hitherto inaccessible were opened up. Heavy machinery, both for the mines themselves and later for the development of hydro-electric power, together with material for the erection of modern metallurgical plants, could now be brought in without prohibitive cost. Low-grade ores could also be shipped to the smelters; the price of mining supplies, such as candles, salt, explosives, and lumber, was reduced considerably; laborers found it possible to buy food at lower prices; and the use of coal for the generation of steam, which before had been restricted because of the scarcity and prohibitive cost of fuel, now became much more widespread.

Even before the accession of President Diaz, mining taxes had been reduced greatly. But to encourage the industry still further, and especially to attract the out-

*About 100 pounds

side capital without which the mines could not possibly be developed, the Mexican Congress in 1884 and again in 1887 amended the Mining Code for the benefit of the foreign investor. The condition of the industry—and, indeed, of the whole country was then such as to demand governmental stimulus. The low price of silver, which characterized the period beginning about 1880, threatened not only the mine proprietors but the revenue of the Government and the economic life of the nation.

Under the Code of 1884, drawn up by a committee of mining engineers and lawyers under the direction of the Department of Fomento and participated in by various States, the mining laws of Mexico were unified, and the powers of legislation on mining affairs was taken from the States. Materials necessary for mining operations were relieved of taxes and import duties, and a maximum limit of 2% was fixed for State taxation. Coal, iron, and quicksilver mines were exempt from all State taxation for fifty years; beneficiating plants could not be taxed at higher rates than those fixed for any other industrial enterprise.

The Code of 1887 granted to the Federal Executive the power to enter into special contracts with companies which should invest not less than P200,000 within five years in mining enterprises or metallurgical works. These companies were granted special franchises, or concessions, relieving them of local, State, and Federal taxes for a period of ten years. Such legislative aids were not innovations either in Spanish or Mexican law; they represented the wishes of mining, financial, and business interests generally throughout the Republic. From the legislation of 1884 and 1887 the development of Mexico's mineral wealth received a surprising impetus. Production of gold and silver, which in 1877 amounted to slightly over 26 million pesos, had risen by 1890 to 43 million. Lead and copper were also being produced in considerable quantities; coal had been discovered in the Sabinas basin of Coahuila and was being mined to good advantage.

RE-APPEARANCE OF FOREIGN COMPANIES. The greater part of this revival was due to the influx of foreigners and of foreign capital. Even before 1884 many Americans had entered the country from the South-Western States; as the excitement of 1849 began to die out in California, scores of prospectors crossed into Sonora or went by boat to Lower California; others took up properties in Chihuahua and Sinaloa. By 1865 over thirty American companies were operating in the northern Mexican States or in the vicinity of Triunfo and San Antonio in Lower California. The investment of these companies amounted to about \$12,000,000. San Francisco and New York were the parent cities of most of these concerns, some of which acquired possession of famous properties, and numbered widely known Americans among their directors. The mines of San Dimas and Guarisamey, which made their owner, Zambrano, one of the great men of New Spain in the 18th century, passed into the possession of New York capitalists. General Lew Wallace and Colonel George E. Church became

the owners of celebrated properties in the Santa Eulalia district in southern Chihuahua. The Batopilas mine, famous for two centuries for the virgin silver it produced but almost abandoned after the Mexican revolution, was purchased in 1861 by James R. Robinson, of New York, who organized the Batopilas Silver Manufacturing Co. and worked the property for 19 years, taking out nearly \$3,000,000 in silver. The discovery of placer deposits in 1878 in the Sierra Mojada region of Coahuila led to a mining rush of large proportions to the new fields. Fully 5000 prospectors from the south-western part of the United States, according to E. L. Doheny of the Mexican Petroleum Co., who was one of their number, took part in this stampede; but as a placer field the Sierra Mojada region proved a failure. In later years, however, its lead-silver deposits made the region famous.

With the exception of a few companies already mentioned, most of the Americans engaged in mining in Mexico before 1880 were prospectors without much capital. They were hardy, virile, and picturesque; but most of them had the typical Westerner's contempt for anything Mexican, and paid little attention to local laws. This was especially true when a party of four or five well-armed men reached some out-of-the-way Mexican village after weeks of prospecting in the mountains. They drank freely, perhaps on occasion 'shot up' the town, and were almost certain to play fast and loose with the girls and young women. Much of the ill-feeling still cherished by the Mexicans in the border States against Americans may be traced to the actions of these early prospectors.

BOLEO AND BATOPILAS COMPANIES. In the early 'eighties the small foreign companies in Mexico began to be reinforced by well-organized concerns, with sufficient capital to revolutionize the mining industry. About 1880 General Frisbie and J. B. Haggin organized the American Mining Co. and took over the El Oro mines, which they controlled until their sale in 1900 to the El Oro Mining & Railway Co. In 1885, French investors, supported largely by the Rothschilds, organized the Compagnie du Boleo with a capital of twelve million francs, to exploit the copper deposits of Santa Rosalia in Lower California. In 1886 a concession was granted by the Mexican government to Alexander Robey Shepherd for the exploitation of numerous silver mines in the district of Batopilas. Shepherd, who had been governor of the District of Columbia under President Grant, came to Mexico in 1879 and bought the San Miguel mine at Batopilas from the Robinson interests, paying \$600,000 for the property. Between 1880 and 1886, Shepherd purchased various other holdings and finally organized them into the Batopilas Mining Co., with a capital of \$9,000,000. Within a short time many other foreign companies were seeking special contracts with the Mexican government under the terms of the law of 1887.

ESTABLISHMENT OF MODERN SMELTERS. Under this law, also, modern smelting plants were established for the first time in Mexico. Previous to 1890, ores that required smelting were shipped to the plants across the

border. This involved such heavy freight charges that few ores could be treated profitably. The inducements offered by the Mexican government to smelting companies were further supplemented by grants, mostly in the form of tax exemptions, from several State legislatures. The low cost of Mexican labor proved an additional attraction. A further reason for carrying the business across the border was the passage of the Windom Law by the United States government, which, in an effort to protect the lead producers of the United States from competition with the product of the Sierra Mojada mines, laid such heavy duties on the importation of lead ores that these could no longer be shipped across the line with any profit, and had to be smelted in Mexico.

The Guggenheims were among the first foreigners to engage in the smelting business in Mexico. A concession was secured under the law of 1887 allowing free importation of machinery, construction material, and coke from the United States. Plants were erected between 1890 and 1895 at Monterrey and Aguascalientes, and somewhat later at Velardeña, Chihuahua, and Matuhuala. All of these are now controlled by the American Smelting & Refining Co. or its subsidiaries. In addition, the same corporation acquired about ten mining properties and an important railroad system.

A number of other smelters were built during the early 'nineties by competitors of the Guggenheims. The Cia. Metalurgica Mexicana erected a large plant at San Luis Potosí in 1892, receiving ores from the mines of at least eight different States. The Peñoles company, at that time a German-Mexican concern, had a smaller plant at Mapimi, in Durango. Later, the Cia. Metalurgica de Torreon, a Mexican concern, built the third largest silver-lead smelter in the Republic at Torreon. All told, besides the smelters maintained by the important copper companies to handle their own ore and care for custom business, seven large silver-lead smelters, with a combined capacity of over 2,000,000 tons per year, were erected in the mining centres of the country.

INCREASE OF FOREIGN INVESTMENTS. In spite of the large investment of foreign capital after 1885 and the organization of the smelting business, the mining industry of Mexico faced a serious difficulty in the early 'nineties, due chiefly to the continued fall in the value of silver. The Government, feeling that this might be offset in some degree by more favorable legislation, passed a law in 1892 making radical changes in the requirements under which mining claims might be held. According to the colonial law, mines left unworked for four months or more reverted to the Crown, and became subject to denoucement. The law of 1884 provided that at least six men must be employed on a claim for not less than 26 weeks out of the year, or ownership was forfeit.

By the law of 1892, however, payment of taxes was made the sole requirement for retention of ownership. The taxes were based upon the number of pertenenencias in a claim, the pertenencia as under previous laws constituting the indivisible unit of mining concessions. Its dimensions were now 100 metres on a side, equal to one

hectare, or 2.47 acres. The rates imposed by the new Code called for the payment of an annual tax of \$10, Mexican gold, in three installments for each pertenencia in a claim, and a stamp tax of the same amount payable upon the issuance of the patent. In 1905 these rates underwent the following modifications: the stamp tax was reduced to P5 per pertenencia, and the annual tax became P6 for each pertenencia up to 25 in a property, and P3 for each pertenencia in excess of that number.

In addition to the revenue this law was designed to bring, its object was to encourage the industry by making conditions favorable for large investments of capital, especially in low-grade properties. Under its provisions, companies were able to denounce large areas; and, by paying slightly over \$1 per acre in stamps and an annual maximum tax of about the same amount, they could hold their properties in perpetuity. The intrusion of rivals could thus be prevented, and a sufficient supply of ore provided to justify extensive development work and the expenditure of large sums for machinery and reduction works. Beneficial though this law undoubtedly was, there were in it two elements of danger: It permitted mining properties to be held for purely speculative ends, and enabled large companies to obtain possession of unreasonably extensive areas for strategic purposes, retaining them undeveloped, to the serious injury of smaller rivals and to the nation as a whole.

The law of 1892 was followed two years later by legislation designed to increase the production of gold. Some such stimulus was badly needed. The price of silver was still low, and Mexico's output of gold, less than \$1,250,000 annually, was wholly insufficient to offset the decline in silver production. The new law permitted the Executive to enter into special contracts for one year with companies or individuals seeking to discover or exploit gold placers. It is significant that the annual production of the metal increased, within one year after the passage of the law, from 59,600 oz. to 235,000 oz., and had risen by 1900 to 444,000 ounces.

Under the stimulus of favorable legislation and the growing sense of confidence in the stability of political conditions, large numbers of foreign companies, most of which were American, entered Mexico. As the foreigner became interested in the industry the Mexican gradually withdrew; little by little the important properties passed out of his control, until by 1912 of a total investment in the mining business estimated at \$323,600,000 he could lay claim to less than \$15,000,000. The following table shows the mining investments by nationalities:

	American	British	French	Mexican*	Miscel.
Mines . . .	\$223,000,000	\$43,000,000	\$5,000,000	\$7,500,000	\$7,830,000
Smelters . . .	26,500,000	7,200,000	3,000,000

*The acquisition of the chief Madero properties by the American Metal Co. greatly reduced the above valuation of Mexican holdings.

As the prosperity of the industry in 1810 was cut short by the Hidalgo revolt, so that which distinguished the first decade of the 19th century suffered an analogous eclipse in the chaos that followed Madero's brief acquisition to power.

Experiences of a Mining Engineer in the Kasin Diamond Fields, Belgian Congo

By J. E. Robison

The Forminière*, a corporation operating in the Belgian Congo, employs a number of American engineers in its exploration and mining activities. The work, up to date, has been confined chiefly to the exploitation of diamonds. The technical part of the undertaking offers little of interest from an engineering standpoint; the great bulk of the work is carried on by hand, necessitating in most cases simple and primitive methods and machines. The great distance from the base of supplies, and the difficulties of transportation, largely account for this.

When a mining engineer who has accepted a position with the Forminière arrives in the Congo he is confronted, not only with a new language and new customs, but with an unfamiliar country; with all of these he becomes more or less acquainted on his trip into the interior. He arrives at Matadi, the port of entry, situated about 50 or 60 miles up the estuary of the Congo river. He then proceeds alternately by rail and water, arriving three weeks later at D'Joko Punda, the head of navigation on the Kasai river and the outlying post of the Forminière. D'Joko Punda is the inland receiving station for supplies. Here the river-boats discharge their cargoes, which are then forwarded to Tshikapa. Tshikapa is headquarters of the Société in Africa. Material is shipped beyond D'Joko Punda by truck, tractor, caterpillar, Ford automobile, or on the backs of native *porteurs*—in fact, by any means so long as it reaches its destination. The engineer continues his journey, by Ford if he is lucky, if not, in a hammock *tepay*, arriving at Tshikapa about four days later. The managing engineer then assigns to him his future work. He is usually detailed to a development or prospect camp, where he is 'broken in' by an experienced man. The development camps are, as a rule, from two to three days travel from Tshikapa, so that the newcomer is virtually in the midst of the jungle at last.

Development is carried on by sinking rows of pits or trenches across the valleys. Usually these are placed at intervals of 100 metres. The work is mapped, and cross-sections are made of the pits, showing the depth of overlying gravel and the contour of the bedrock. The gravel is washed and classified in screens of the hand-rocker type nesting in each other. The resulting classified products are treated on Joplin jigs, and the concentrate is hand-sorted for the diamonds. Reports are then made on each pit, showing the volume of gravel washed, the diamonds recovered, and the percentage of each size of classified gravel based on the 'meterage' washed.

The new man is left with the experienced engineer for about two weeks, during which time he becomes familiar with the methods in vogue and also acquires a smattering of the native dialect. The older engineer is then transferred to another post, and the newcomer assumes charge. Then commences his fun and his real initiation. He has by this time a cook, a personal boy, and sundry other servants; he soon learns that his vocabulary is so limited that if he orders eggs for his morning meal, he may be served sweet potatoes, or anything other than what he wants; in his own obtuseness he blames the native, who suffers accordingly. He experiences the same difficulty in carrying out his work, but fortunately he has fallen heir to a trained crew. During this period he is being tested by the natives, who become lax in their work and in various ways tax his patience until he demonstrates the stuff of which he is made; then things hum along in their accustomed way. He is christened with a new name, according to native fashion, that is indicative usually of some physical characteristic or a peculiar trait: the native equivalent of 'Slim', or 'Shorty', or 'Patty'. If the engineer is of the choleric type he will receive such names as 'The Leopard' or 'The one who beats them'. The name 'The Leopard', for instance, signifies that the workers should be wary of him; for, like the animal in question, he may spring at them. The name that an engineer receives is important, for, if it signifies a hard man to deal with, he will as a consequence find it difficult to secure native laborers or to hold them in his employ. This is the one big problem that either helps or retards his work. Food and game usually abound, and there is no reason why a native should work except to accumulate enough money to purchase a wife. All wives are acquired by purchase in the Congo; they pay the price before marriage; we, as a rule, pay it afterward.

Taking into consideration the fact that economic pressure does not force a native to work, it devolves on the engineer to make working conditions as attractive as possible in order that the natives shall be fairly contented and happy while under his supervision. To do this he must see that they are well housed and that their living conditions are attractive from their standpoint. He must maintain, if possible, an adequate and diverse supply of food. He becomes a 'chief' to the natives in his immediate neighborhood, who look on him as their protector as do his workmen. He is called upon to adjudicate all sorts of grievances, ranging from petty theft to various martial infidelities leading to divorce, all of which must be settled according to a curious mixture of native custom and his own ideas of justice. The natives accept the

*Société Internationale et Forestière et Minière du Congo.

decisions generally without question, and gradually the white man acquires an influence and authority that materially assist him in carrying on his work.

The engineer's custom of administering treatment in case of injury or sickness tends to foster among the natives a sense of protection, and show them the advantages of being in the white man's employ. The ills will range from wounds and pernicious ulcers to fevers and various chronic ailments. So, with inspiration as his Esculapius, the engineer delves into his medicine-chest and proceeds to prescribe, his usual panacea being a strong purgative. It is not quite as haphazard as it sounds, for he is furnished by the resident physician at Tshikapa with various medicines for prevalent diseases. All of this goes to make up the daily routine of the engineer while 'off shift': it serves to make an interesting life of what otherwise would be a drab existence. However, he is thankful when the end of his two-year contract comes, and when civilization and the good old U. S. A. loom on the horizon.

The engineer, after remaining on development work for five or six months, is usually relieved by an incoming engineer and is then given charge of a party on exploitation. Whereas, formerly, he had perhaps 100 laborers, he will now have 600 or 700 with their attendant families, and his duties in looking after them will be increased proportionately. Exploitation camps in general are equipped with hand-operated six-foot Kimberly washing-pans. These pans treat all the undersize gravel from a two-mesh trommel, the oversize from which is stacked for future treatment. The pans are cleaned about every hour; this of course varies according to the diamond content of the gravel washed. The resulting concentrate is re-concentrated in various types of hand-jigs and is then run over greased tables. The Société is at present installing mechanically operated units, but will adhere to the same flow-sheet.

Formerly the gravel was classified in four trommels in series; 2-, 4-, 8-, and 16-mesh screens were used. The three intermediate sizings were concentrated in Joplin jigs, and the concentrates resulting were hand-sorted. However, this method has given way almost entirely to the pan-plant method. The methods employed in working the shallow alluvial deposits are identical with those of the old Californian 'forty-niner' in 'shoveling up'. Bedrock is cleaned in the same way also. The gravel is transported to the washing-plant in small wicker baskets, which the natives carry on their head. The basket-loads average about 125 to the cubic metre. The small river valleys are generally heavily forested; clearing is carried on by ordinary methods; the larger trees are suitable for lumber, which is prepared by the whip-saw gang.

The engineer's work in an exploitation camp entails a variety of tasks other than mining. He must maintain roads in the vicinity in good condition and must build new ones if necessary. About 10% of the employees are engaged in plantation work. *Manioc* is grown extensively, as this is the principal article of food for the natives. Much attention is devoted also to the cultivation

of bananas, paw-paws, and various other tropical fruits. He will have from 75 to 150 acres of land under cultivation, the area being increased gradually. The idea is to make each camp as nearly as possible a self-supporting unit. In conjunction with the main farm he will also have his own vegetable and fruit gardens. He keeps time for the men and pays them, besides operating a store to supply their needs of cloth, beds, and other items. He is called upon to train carpenters, blacksmiths, brick-masons, and, in fact, all the special men necessary for the operation of the plant. Keen is the engineer's disappointment when his carpenter or cook, on whom he has spent hours in developing some degree of proficiency, leaves the job. It means that, if a trained man be not available, the training process will have to be repeated.

Patience is indeed a virtue in this work; a choleric engineer only makes things worse; he drives men away from him. The wages for the different kinds of labor are regulated so that there is nothing for a native to gain by working for a neighbor unless it be better conditions and a more kindly treatment. On the other hand, it is obvious that strict discipline, which is absolutely necessary, cannot be coupled with leniency. The engineer must cultivate a mixture of sternness and kindness, coupled with an absolute aloofness from his men in order to hold their respect. Without respect he can accomplish nothing.

METALLIC magnesium may be derived from several non-metallic minerals. It is produced in this country by the electrolysis of fused magnesium chloride at one plant, and of fused magnesium oxide at the other plant, states a U. S. Geological Survey bulletin. The Dow Chemical Co. uses hydrous magnesium chloride for the manufacture of metallic magnesium. The chloride, mixed with common salt in the proportion of 4:1 and with a small quantity of ammonium chloride, is heated in shallow vats over a slow coal fire to remove its combined water. About 50% of the water is driven off in this way. The partly dehydrated mixture is removed from the vats, cooled, and then completely dehydrated in a second furnace with higher temperature. The metal is then produced by electrolysis of fused magnesium chloride in a bath of salt and ammonium chloride. The electrodes used are graphitized carbon, and electrolysis takes place in cylindrical sheet-iron cells, which serve as cathodes. The American Magnesium Corporation uses magnesite mined on the Pacific Coast and calcined before shipment to the plant at Niagara Falls. During calcination the weight is reduced by one-half, owing to the removal of a large amount of carbon dioxide. The firm produces magnesium by electrolysis of the fused oxide. The electrolyte or bath is a mixture of fused fluorides, the oxide going into solution and being decomposed by the electric current. The slag is removed, and the metal is drawn from the furnaces at hourly periods and poured in small ingot molds. The metal is afterward refined. This is effected by re-smelting the ingots in small retorts.

REVIEW OF MINING

SENATOR W. A. CLARK OPTIONS PROPERTY AT OPHIR, UTAH

The Ophir Hill Consolidated Mining Co., owned by ex-Senator W. A. Clark, has taken a lease and bond, with option to purchase for \$115,000, on the property of the Ophir Coalition Mines Co. The Ophir Coalition property consists of 12 patented and several unpatented claims, and joins the Ophir Hill property on the west and south-west. Most of the Ophir Coalition stock is held by Chicago interests. There has been developed in the property a large tonnage of mill-ore, which can be treated in the Ophir Hill mill. The Ophir Hill people have recently constructed a flume from the mill, past the town of Ophir, to a point a considerable distance down the canyon. It is believed that the company is planning on treating the mill-dump by the flotation process, and will use the new flume for conveying the re-treatment tailing to a new dump. Experiments have been in progress for many months at the Ophir Hill mill investigating the applicability of the flotation process.

HOLLINGER CONSOLIDATED WILL SUBSTITUTE BALL-MILLS FOR STAMPS

It is understood that the Hollinger Consolidated is planning to increase its capacity to a maximum of 6000 tons daily by a change in grinding equipment. This will involve the discarding of the 200 stamps now in use and substituting 10 ball-mills, each having a capacity of 600 tons daily, operating in connection with the 20 tube-mills which form part of the present equipment. If this project is carried into effect it is believed that the grade of the ore may be reduced to about \$8 per ton, so as to include a large amount of low-grade lying on the Millerton side of the property. At present the mill is treating from 3500 to 4000 tons of ore daily.

TENNESSEE COPPER & CHEMICAL CO. IS EARNING A PROFIT ON CURRENT OPERATIONS

The Tennessee Copper & Chemical Co. has started on an era of expansion which has removed it from the class of mining enterprises to that of an industrial producer. Today the company ranks as the largest producer of sulphuric acid in the country, although the cotton market and the small demand for fertilizers has caused the company to curtail output.

The company estimates its 1921 output of copper and acid, in comparison with two preceding years, as follows:

	Copper, lb.	Acid, tons
1921 (estimated)	8,127,296	236,707
1920	10,358,237	333,629
1919	10,414,815	266,627

Consolidating the operations of the various departments the Tennessee company in the first eight months of this year made net profit of \$339,140, before depreciation but after fixed charges and after absorbing a book-loss of Southern Fertilizer Co. This loss was brought about by inventory write-offs. The parent company and its subsidiaries have quick assets of close to \$3,000,000, of which \$400,000 is cash and \$715,000 notes and accounts receivable.

The chemical plant built and turned over to the Southern Fertilizer Co., a subsidiary, has a rated capacity of 100,000 tons of acid phosphate per year.

Under an agreement with the Internal Revenue department the Tennessee management charges between three and four cents per pound of electrolytic refined copper for depletion. Wages now paid employees are below the peak-level, yet are higher than the pre-war level. Greater efficiency has been attained, making it possible to lower production costs of both copper and sulphuric acid in the face of curtailing output.

SAN FRANCISCO MINT IS BREAKING RECORDS

The United States Mint at San Francisco is now operating 24 hours per day, coining 260,000 silver dollars daily. So efficient is the work at the plant that the Director of the Mint at Washington has sent Samuel J. Ward, who for many years has been foreman of coiners at the San Francisco mint, to Philadelphia, with the hope that the work at that plant can be speeded up. It is expected that the interest-bearing debt of the Government will be decreased by \$65,000,000 within the next 90 days as a result of the production of silver dollars under the terms of the Pittman Act.

CHIEF CONSOLIDATED CO. COMMENCES SHIPPING HIGH-GRADE LIMESTONE

The lime quarry of the Chief Consolidated Mining Co. at Eureka, Utah, is ready to commence production. The company has closed a contract with one of the large smelting companies, calling for a clean screened lime ranging from 1 to 2½ in. diameter. Contracts with sugar companies call for a product varying from 2½ to 6 in. diameter. The deposit is one of exceptional purity, averaging between 98 and 99% calcium carbonate. It is estimated there are between four and five million tons in the deposit. Initial production will be at the rate of 150 tons per day. Contractors are constructing bins and trestles, and crushers, screens, and conveyor-belts are on the ground, awaiting installation.

SENATOR ODDIE WRITES IN FAVOR OF THE McFADDEN BILL

In a letter to A. W. Mellon, Secretary of the Treasury, T. L. Oddie, Senator from Nevada, criticizes the Secretary for following the gold policy initiated by the last Administration, which he says has affected our domestic industrial condition, export trade, and maintenance of the gold standard. He says the prophecy of the Treasury Gold Committee more than two years ago that commodity prices would decline has failed to materialize, as prices have gone so high as to shut-down gold mines. The Senator says the Treasury argument that gold mining must wait for lower prices for relief is not tenable, as the general price-level is rising instead of declining. He insists that the normal condition of the industry cannot be restored unless the purchasing power of the dollar in 1913 is restored. Senator Oddie warns that unless relief is afforded the mining industry ore-reserves will be lost through caving of mines.

He concludes by saying: "The production of gold throughout the world is declining, and unrestricted industrial consumption for years to come would be so large as to reduce the amount available for monetary purposes. This condition must be remedied if the gold standard is to survive this period of readjustment. The industrial gold consumption of the world should, therefore, be forcibly curtailed and gold production stimulated. Both of these conditions should be satisfied by an equitable adjustment in the cost and price equation between the producer of new gold and the industrial consumer. The McFadden Bill provides for such an adjustment. This constructive gold policy put into effect at this time will safeguard the maintenance of the gold standard. Such a policy is also prerequisite to a more rapid revival of our domestic industry and export trade upon which the full time employment of our people and the prosperity of the nation depends."

FLOOD AT BRITANNIA MINE, HOWE SOUND, B. C., DESTROYS LIVES AND PROPERTY

A destructive flood, following continuous rain for a month, swept the property of the Howe Sound Mining Co., on Britannia beach, on the evening of October 29. Communication with the mine has been cut and details are lacking, but it is known that a number of persons lost their lives and that half of the buildings in the settlement were washed away. C. P. Browning, superintendent at the mine, turned the assay-office into a morgue. The dispatches make no mention of damage to the mine plant. About a year ago the company's concentrator was destroyed by fire.

PRODUCTION STATISTICS IN THE JOPLIN DISTRICT

During the week ended October 22, zinc held at \$25, but operators were generally optimistic and predicted that the future still appeared bright. Lead continued at \$60. The total purchase for the week was 6320 tons. Following were the shipments, in pounds and value:

Oklahoma	Blende	Lead
Admiralty Zinc Co.....	1,794,950
Bilharz M. Co.....	1,118,490	86,970
Black Eagle M. Co.....	189,530
Blue Ribbon M. Co.....	89,320
Colgate M. Co.....	88,950
Dorothy Hill M. Co.....	347,030
Desperation M. Co.....	32,920
C. & S. M. Co.....	218,160
Donado M. Co.....	440,200
E. & S. M. Co.....	458,750
Golden Rod M. & S. Co.....	342,200
Hartford M. Co.....	1,066,730
Harrisburg M. Co.....	180,190
Huttig L. & Z. Co.....	1,345,700
Laclede M. Co.....	433,090
New Chicago M. Co.....	79,910
Oko M. Co.....	877,860	65,786
Premier M. Co.....	336,800
Red Bird M. Co.....	515,000
Rialto M. Co.....	178,160
Seale M. Co.....	78,260
Skerton M. Co.....	388,150	127,930
St. Joe M. Co.....	281,860
Vantage M. Co.....	690,780
Victory M. Co.....	912,450	92,590
Vinegar Hill Wren.....	400,820
Sundries.....	1,450,220
Total.....	11,454,180	1,757,710
Value: blende, \$143,000; lead, \$53,080; total, \$196,080.		

Kansas	Blende	Lead
Big Elk M. Co.....	84,420
Blue Mound M. Co.....	86,480
Chanute Spelter Co.....	583,320
Empire Development Co.....	259,480
King Brand M. Co.....	133,780	83,460
Lawyers M. Co.....	362,620	249,970
Muncie M. Co.....	91,960
Sundries.....	458,890
Total.....	1,517,540	793,280
Value: blende, \$18,750; lead, \$23,760; total, \$52,510.		

Missouri	Blende	Lead

Barnsdall M. Co.....	1,599,460
Sundries.....	65,000
Total.....	2,470,310	65,000
Value: blende, \$30,750; lead, \$1921; total, \$32,671.		

District

The week: blende, 15,422,030 lb.; value, \$192,500; total lead, 2 315,990; value, \$78,761; total value for week, \$271,261.

Average value per ton: blende, \$25; lead, \$60.

46 weeks: blende, 458,162,650 lb.; \$5,192,380; calamine, 60,430 lb.; \$360; lead, 102,853,720 lb., value, \$3,368,767; total value, \$7,847,852.

UNION OIL CO. OF CALIFORNIA PURCHASES PROPERTY NEAR VANCOUVER, B. C.

The Union Oil Co., of California, has obtained an option on the British Columbia Refineries' property, near Barnet, and has purchased the old Kirkpatrick shingle-mill. Officials of the company have been in the city for a week, and have inspected all available property on Burrard inlet. It is understood that the Union company proposes to establish a refinery business in competition with the Imperial Oil Co., which up to now has had a monopoly of the business. For long the Union company has supplied the C. P. R. Owing to the continued high price of coal, the C. P. R. is gradually converting a number of its coast steamers from coal- to oil-burners, and the new trans-Pacific liners, which will go into commission early next year, are oil-burners, while it is stated that those now in service are to be converted as soon as the new boats arrive on the Coast. Consequently the C. P. R. will use much more oil in the future than it has done in the past. The Kirkpatrick mill is to be used as a distributing station.

ALASKA

Seward.—The House Committee on Territories at Washington has reported a bill appropriating \$4,000,000 to complete the construction of the Government railroad between Seward and Fairbanks. There remain to be constructed 61 miles of track, and two steel and concrete bridges. The railroad taps two coalfields and six mining districts.

ARIZONA

Oatman. The Big Four and Henry Ford groups, of the San Francisco district, have been merged into a company, to be known as the Katherine Big Four Corporation, which will be incorporated under the laws of the State of Delaware, for \$1,000,000, one-half of which will be placed in the treasury for development purposes. The promoters of the corporation have subscribed in the neighborhood of \$40,000, as provided in their agreement of purchase, for the immediate installation of machinery and sinking deep main shafts on each property as rapidly as possible. The Big Four

group consisting of 90 acres, lies contiguous to the town of Katherine on the east, and about one-quarter mile from the Gold Chain group on the north; in fact a huge cross-vein from that group intersects the main vein of the Big Four group. The main vein, where cross-cut by trenching, shows value of \$2 to \$4 gold for a width of 40 ft. The Henry Ford group consists of 70 acres lying in the vicinity of the Old Hardy group, in the Oatman district, which latter group in the early days shipped in the neighborhood of \$200,000 in high-grade ore from superficial workings to San Francisco smelters, by way of pack-train to Colorado river, and thence by boat through the Gulf of California. The main vein of the Henry Ford group shows the characteristic 'waxy' ores of the richer veins that have been developed in the Oatman section. A parallel vein to the main vein occurs also upon the property, 187 ft. away, that shows a zone of highly mineralized vein matter.

CALIFORNIA

French Gulch.—Thomas Salisbury, who has an option on

Grant, consisting of 5000 acres. The remaining 39,369 acres have been sold to other purchasers. Messrs. Kelso and Holmes plan to sink a new shaft at the old Princeton mine, where there is a 15-stamp mill and a mine-plant worth \$150,000.

Silver City.—The Comstock Eldorado Co. has acquired the Dixon & Rain on the Lager Beer property, where excellent ore is exposed. The Flora Temple mine has also been leased and both will be worked under the supervision of Carl Stoddard.

Utah.—The old Sulphur Bank mine, situated at the lower end of Clear lake, once regarded as the richest quicksilver mine in the world, with a payroll of 700 miners, has been bought by Mocine & Martin for the New Idria Mining Co. It is understood the mine will again be operated. In old days great difficulty was experienced in working the mine because of gas, acids, and boiling water, which made it impossible for the miners to work longer than 15-min. shifts. The mine was closed down 20 years ago, but during the War

Howe Sound. The Britannia Mine, on the Sound, Was Visited by a Flood on October 29

the Washington mine, has commenced exploratory work. —The company that is working the Gladstone mine has cleaned out 8000 ft. of drifts and cross-cuts preparatory to resuming production.

Grass Valley.—The Randolph Consolidated Mines Co., with a capitalization of \$500,000, has been organized to develop mining properties in the Randolph section. H. L. Ostrander is at the head of the company. The ground was worked by placer methods years ago. The intention now is to develop the lodes.

Hayden Hill.—High-grade gold ore has been found in an 18-in. vein on the La Ora claim, according to William Snyder. This indicates that the high-grade ore in the district is not entirely confined to the Juniper mine, and that the ore-zone is wider than originally supposed.

Lewiston.—The Gardella dredge on the Paulsen ranch is ready for launching. The flume that will carry the water to the pit is nearly complete. The boat is 88 ft. long and has a 40-ft. beam.—C. P. Richards and P. C. Linderman have driven an 800-ft. adit in the Blue Jay property, on which they have an option.

Mariposa.—T. E. Kelso and William Holmes have purchased the mineral-bearing section of the famous Mariposa

the dumps were worked over and a considerable amount of quicksilver obtained.

COLORADO

Alma.—The London mine is shipping steadily while developing through a cross-cut tunnel projected to open ground 600 ft. below the present deepest workings.—The Dolly Varden is shipping steadily, the general average is \$100 per ton, while sacked ore as high as \$500 per ton is shipped in carload lots.

Boulder.—The old Caribou Hill district is being revived and the adjacent ground is being re-staked. Chief among the many rich mines on the main hill is the Grant County shaft, which is being operated by the Caribou Hill Mining Co. It has opened richer and larger bodies of ore in virgin ground than the famous Caribou mine, which it adjoins. Several veins of practically pure silver, which run from 2 to 4 in. wide and a number of larger veins of ore that average from \$20 to \$140 per ton have been opened.

Breckenridge.—The Tonopah Placers Co. is prospecting near the northern edge of town with a Keystone drill, and, if results are favorable, ground on the west side of the Blue will be dredged. One dredge is now operating profitably on the Blue river below the city.

Colorado Springs.—At the annual meeting of the Fanny Rawlins Mining Co., of Leadville, held in this city on last Monday, John Himebaugh was re-elected president for the thirteenth consecutive term, Alvin Perrine, vice-president, W. C. Frost, secretary. B. F. Webster, C. D. Hart, C. O. Glese, and H. A. Young complete the board of directors. The Leadville property, operated under the leasing system, is producing steadily.

Cripple Creek.—The Ajax Mines Leasing Co., operating the Ajax mine on Battle mountain, has made a rich discovery at the bottom or 20th level. Ore found on the main Ajax vein samples 15 to 18 oz. gold per ton.—A surface discovery of importance has been made by Louis Pelland, an old-timer of Cripple Creek, on the Cameron townsit at the eastern base of Bull hill. The vein, 2 ft. wide at a depth of 25 ft., samples 2 to 3 oz. gold per ton.

Idaho Springs.—A Denver syndicate has taken over the Gold Medal group and Wyoming Valley tunnel properties and arrangements have been made for extension of the tunnel traversing the Gold Medal.—A second shift has been put to work by the Surety Mining Co. on its Ute Creek property and development work will be continued during the winter months.

Montrose.—Reports have reached this city of a rich gold discovery made on Uncompahgre, on the Big Cimmarron river, by local prospectors—Alfred Harris, V. L. Miller, James Huffman, and James Viller. The men, completing assessment on their lode claims, are reported to have exposed a vein from which a sample assayed 150 oz. gold with a second vein, more than 4000 ft. distant, sampling 534 oz. gold and 46 oz. silver per ton. Several local mining men have left for the neighborhood of the discovery to stake claims.

Silverton.—Supplies have been sent in to the Holmgrain properties in Placer gulch, operated by the Hanson Peak Mining Co., and to the Queen City mine, where operations will be continued during the winter. Both properties are producing high-grade silver-lead ore.—Pack-trains are kept moving silver-lead ore down to Gladstone from the Joe & John mine, operated by the Golden Consolidated Mines Co.—Lessees on the Whale are shipping rich gold ore to the smelter.

Through the efforts of Herbert E. Curran, acting as receiver, Pittsburgh capital has been interested in the Kittimaac mines in Minnie gulch. The work being done is under the direction of H. G. Brient. His preliminary investigations have proved encouraging. The property has within its boundaries several large gold-bearing lodes.

At Mineral Point, William A. Triplett has been active in the development of the London mines. One car of ore recently shipped from shallow deposits, consisting of galena and gray copper ores, is reported to be rich in silver, hand-samples of the lot carrying 70 oz. per ton.

J. B. Giono, operating parts of the Silver Lake mine of the A. S. & R. Co. under lease, has just shipped a car of ore assaying more than 8 oz. gold and 70 oz. silver, with 24% lead. The strike of rich ore of this character was entirely unexpected and has given an added encouragement to operations in Silver Lake basin.

IDAHO

Coeur d'Alene.—The International Mining & Metal Corporation, owning the inland property in the north-west part of the Coeur d'Alene mineral belt, has resumed operations and let a contract for a 50-ft. extension of the drift on the vein, according to C. A. Gray. This drift is to follow the footwall side of the vein. The full face of the drift is quartz and siderite. The ore assays 6.8% copper, 14 oz. silver, and 0.04 oz. gold. The plan of development is to sink a winze 300 ft. deep on the vein near the end of the 300-ft.

adit. Ore from the winze, which is down 10 ft., assays from \$88 to \$106 per ton in zinc, lead, silver, and copper.—With the organization of the Galena Mining Co., the Chicago-Boston Mining Co. and the Killbuck Mining Co. will pass out of existence. The Callaban Zinc-Lead Co. will control the new organization, as it did both of the others. The property lies a mile west of Wallace, and is being developed at the present time.

MISSOURI

Joplin.—The Indiana Mining Co., of Joplin, has filed articles of incorporation, with a capital stock of \$150,000, of which \$80,000 has been subscribed. The chief asset of the company is a mineral lease on a proved 80 acres, situated north of Carl Junction. F. H. Kissling, of Joplin, is the principal stockholder.

Sarcoxic.—Prospecting on the Pierce farm, north-east of this city, has resulted in a strike of an 18-ft. face of silicate zinc ore at a shallow depth. Drilling is proceeding, with no indication of exhaustion. The Pierce farm is new territory. On the Thomas place, east of the Pierce farm, there has been more extensive prospecting, interrupted to some extent by legal proceedings regarding the rights of some of the prospectors. On the Solomon-Palmer lease, one mile south of Larussell, the finding of lead ore at 40 ft. is announced by the prospectors.

MONTANA

Butte.—In view of lower wage-scales now prevailing and reduced price of cyanide the East Butte company has resumed operations at its Elkhorn property, situated north of Butte. This property was developed several years ago primarily for the iron, which was used for fluxing purposes at the East Butte smelter but it was found that the ore carried gold averaging from \$8 to \$10 per ton. It is estimated that fully \$500,000 of ore has already been uncovered. When the iron was no longer needed as a flux the property reverted to a strictly gold enterprise. During the War the property was closed down. A \$500,000 mill was erected on the property several years ago, when developments had advanced to a point that warranted its construction. It is hoped to treat at least 250 tons of ore daily, so that East Butte should derive a substantial revenue from its operation.

NEVADA

Cherry Creek.—A. Z. Smith, of Silverhorn, is opening the Exchequer mine under long-term lease. High-grade silver ore was recently found by the lessees when cutting a station in the shaft with a view to cross-cutting to the north vein on the 200-ft. level. The orebody, between 3 and 4 ft. wide, averages 52.5 oz. silver. Drifts run both ways on the vein for a distance of 15 ft. are still in high-grade ore, with no indication of the limits of the ore-shoot as yet in sight. Arrangements have been made to ship about 8 tons per day from the property to the American Smelting & Refining Co.'s plant at Garfield. Returns from a carload already shipped by the lessees from another portion of the property netted over \$30 per ton, after freight, treatment, and royalty charges were deducted.

Ely.—Notwithstanding the fact that the Ely district mines are practically closed and the smelters idle, the futuro is promising. Since the shut-down of the mines, the Nevada Consolidated Co. has been developing what promises to be a very extensive body of high-grade copper ore, which was first discovered at Ruth about ten months ago. The ore, which is direct-smelting in character, assays 5 to 25% copper. The new body of ore is said to have been developed to a depth of more than 700 ft.; it is one of the largest bodies of high-grade copper ore discovered in recent years. And in addition to the discoveries and new bodies of ore blocked out by the Nevada Consolidated company, the Con-

solidated Coppermines and the Boston-Ely companies are now opening high-grade ore, the latter in the eastern end of the district.

It is said that in one section of the Ely Northern property there is now exposed a body of ore 18 ft. wide which will average around 15%. Still farther to the east, on the extreme limit of the range, Al Meyers and associates, who have a lease on the Ely-Calumet property, are developing lead, copper, and zinc ores, which can be shipped to the smelters at a profit under ordinary freight-rates. The splendid results in these two properties naturally lend credit to the belief that the eastern end of the district will become important.

Ploche.—Development of the Alps mine to the east of Ploche is progressing satisfactorily, and already 10 tons of high-grade ore is ready for shipment. Assay of this material gives the following results: gold \$6, silver \$8.2 oz., and lead 40.5%. The ore is being mined principally from the east drift on the 200-ft. level, where the vein is narrow but rich. A raise put through where the vein widened is opening a satisfactory tonnage of milling ore, assays indicating a value of approximately \$20 per ton in gold, silver, and lead.

Rochester.—A slight improvement over August in value of ore mined, in recovery, and in net operating profit is shown in the report for September of C. A. Bennett, general manager for the Rochester Silver Corporation. The tonnage treated was below that of the preceding month. In September the mill treated 4913 tons, as against 5271 tons in August. Metal contents of the ore were 0.147 oz. gold and 11.48 oz. silver, while in the preceding month these figures were respectively 0.159 and 10.66. New development work in September aggregated 540 ft. Bullion recovery in September was \$59,298; total operating expense at mine, \$39,439; gross operating profit, \$19,858; and net operating profit, \$18,431.

OKLAHOMA

Cardin.—In the face of adverse conditions, the lead and zinc mines of Cardin are paying \$25,000 per week for labor, according to reliable estimates. This is one-fourth as much as the weekly payroll under war-time conditions. The average weekly check is about \$21 and about 1200 miners find employment here. About 75% of the mines are operating. Two drill-rigs are being operated in West Cardin by the Commerce Mining & Royalty Co., which is prospecting new deposits. The Golden Rod Mining & Smelting Corporation keeps two rigs busy drilling in the west part of town.

The Croesus Mining Co. in Southeast Cardin has struck a large 'run' of lead in its upper level at 145 ft., which it has been developing for the last six weeks, according to W. H. Aul, superintendent. About 40 men are employed. The second level is at 208 ft. Operations were resumed on August 10.—The Victory Metal Co.'s mine in West Cardin has been operating for the last three months and is now on a double-shift basis, using about 60 men. They are working at a depth of 235 ft.—The Harrisburg No. 1 mill, owned by the Golden Rod interests, is operating, using about 60 miners. They are working at a depth of 200 feet.

OREGON

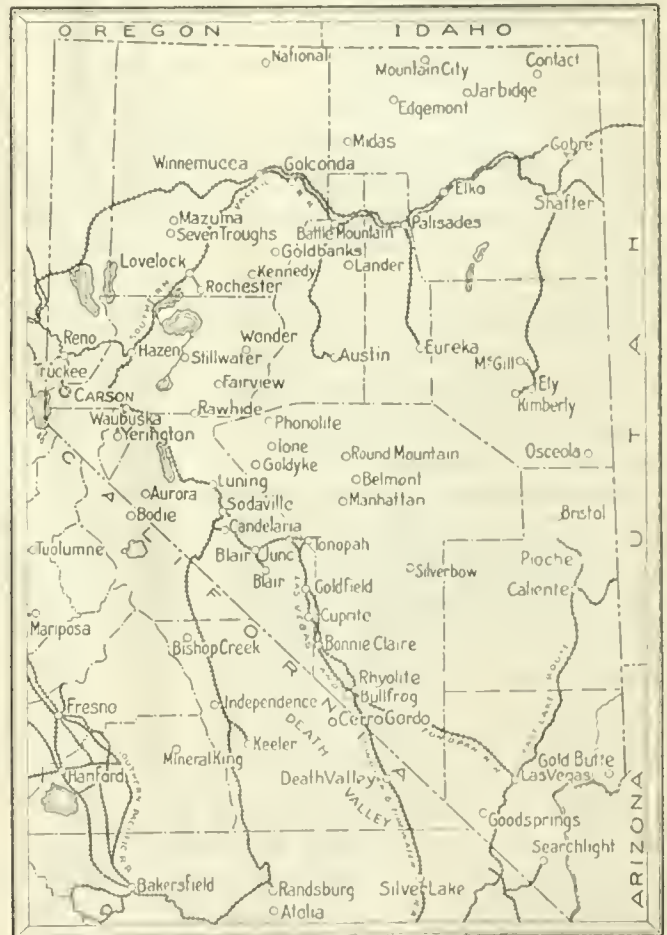

Huntington.—Reports from the Bay Horse mine on the Snake river, about eight miles below here, indicate that rich silver ore has been found. Recent samples gave results of 66.8 oz. silver, 164.8 oz.; 24.6 oz.; 32.4 oz.; 74.8 oz.; 189.6 oz.; 101.4 oz.; 172.0 oz.; with copper averaging about 1%. The property is only 84 miles from a custom smelter, this being at Sumpter, owned by the Sumpter Valley Smelter Co. It is expected the smelter will be ready to treat ore by the time the Bay Horse is prepared to mine and ship ore regularly. P. H. Millier is manager.

UTAH

Big Cottonwood Canyon.—Judgment against the East Carbonate Mining Co. for \$701 was awarded Frank, Iver, Oscar, and John Forsman in a jury verdict returned before Judge Ephraim Hanson of the Third District Court on October 25. The money was owing the plaintiffs on a contract to drive a tunnel through the mining company's property.

The Cardiff Mining Co. is producing from 40 to 50 tons of ore per day, averaging from \$45 to \$55 per ton. Repairs are now under way at the ore-bins at the mouth of South Fork. During the winter season, the mining company stores its ore in these bins.

The American Metal Mines Co., which has acquired the holdings of the American Con. Copper Co. in South Fork,

Map of Nevada

has started deep development work. A number of strong veins, carrying silver and copper minerals, were prospected in the quartzite. These fissures are to be explored in the underlying limestone. The work will be done through a drift from the Victor Mines tunnel, which is about 550 ft. from the American company's line. The American Metal Mines has taken a lease and bond on a strip of Victor ground, 160 ft. wide, the purchase price to be \$30,000.

Eureka.—A contract has been made between the Eureka Hill Mining Co. and Patrick Sheehan, covering the re-treatment of the tailing dump at the old Eureka Hill mill, which was one of the pioneer concentrating plants in this district. Jackson McChrystal, manager for the company, estimates that the dump contains 180,000 tons, averaging \$1 in gold, 5 to 7 oz. in silver, 1.3% lead, and 0.2% copper. Sheehan and associates plan an up-to-date milling plant of 100 tons daily capacity. As to the method of treatment to be used, Sheehan is non-committal.

Ore shipments for the week ending October 22 totaled 172 cars, as compared with 142 carloads for the preceding week. The Tintic Standard shipped 70 cars; Chief Consolidated, 46; Victoria, 11; Iron Blossom, 7; Eagle & Blue Bell, 7; Grand Central, 6; Iron King, 6; Dragon, 4; Swansea, 4; Sunbeam, 3; Gemini, 2; Empire Mines, 2.

All work at the Grand Central mine is now being done by lessees, according to William D. Loose, superintendent. About 6 cars of ore per week is the average output. With the resumption of work at the Mammoth mine, adjoining the Grand Central, lessees in the latter property will be able to make greater headway by using the Mammoth workings for transporting ore and supplies.

A blower of a type similar to that used in coal mines will be installed immediately in the Water Lily shaft; it will have a capacity of 20,000 cu. ft. per minute. At a depth of 1200 ft. the shaft became filled with a heavy, hot gas, similar to that found in the Tintic Standard and other mines in the eastern part of the district.

At the Eureka Mines Co.'s property, a promising body of ore is being followed to the east on the 1000-ft. level. This deposit is believed to be the downward extension of the ore-body opened on the 900-ft. level, according to Jackson McChrystal, manager. McChrystal states that present shipments average from 30 to 40 oz. silver and from 10 to 20% lead.

Grantsville.—Mining is being resumed in the Free Coinage district in the Stansbury mountains, about 9 miles from here. At the property of the Falk Mining Co., ore has been uncovered which gives returns of \$27 per ton in gold, silver, and copper, according to report by J. T. Breckon, mining engineer. This property is controlled by K. H. Nordberg and associates.

Marysville.—The American Consolidated Mines Co. has begun development of the I. X. L. mine in the Mount Baldy district, according to George H. Hamphill, manager. Operations have been started in Danielson tunnel. This adit follows an incline on the lime-quartzite contact. A sample taken in the tunnel gave returns of \$1.60 in gold, 57 oz. silver, and 21% lead.—The Deer Trail Mining Co. is now employing 125 men, and treating from 100 to 125 tons of ore per day in its concentrating plant. Most of the ore now being milled is from development work.—At the Bully Boy mine 15 men are employed on development work.

Ophir.—Guy LaCoste, president of the Ophir Silver Mines Co., which lies to the east of the Ophir Hill property, reports that a tunnel is to be driven in Economy No. 13 claim. The tunnel will be for the purpose of deep development and to explore at depth a high-grade silver-lead orebody entered last fall on the 500-ft. level. A compressor and other machinery will be installed.

Park City.—Ore shipments for the week ending October 22 totaled 1556 tons, of which the Judge allied companies shipped 839; Silver King Coalition, 609; Ontario, 438. Shipments the previous week totaled 2190 tons.

Conditions continue to improve at the New Quiney property. A winze has been sunk for a distance of 75 ft. in a lime bed, with ore showing all the way. The winze is approximately 4000 ft. from the Little Bell shaft. The ore-shoot is from 20 to 30 in. wide.

BRITISH COLUMBIA

Grand Forks. A 10-ft. body of ore has been opened in the pyroxenite belt, locally known as the 'black lead', at Franklin camp. The ore assays 4.3% copper and 0.11 oz. of platinum per ton. William Thomson, while working for the Munition Resources Commission, demonstrated that platinum occurred in bunches and veinlets of chalcopyrite at a number of points in this belt, and last year the Provincial government operated a drill in the hope of finding

ore. J. B. Singer has traced a 7-ft. vein for more than 1000 ft. on the White Swan group, which adjoins the Molly Gibson. A foot of this vein consistently assays \$31 in gold per ton.

Nelson.—Wilfred A. Cameron, lessee for the Rambler-Cariboo mine, has taken a lease on the Molly Gibson mine, on Kokanee creek, from the Consolidated M. & S. Co. This mine should not be confused with the Molly Gibson, at Paulson, in the Grand Forks division. The Consolidated bought it several years ago, and operated it until the end of last February. During the two months that it was worked last year some 300 tons of silver-lead ore was shipped.—J. B. White, president of Silversmith Mines, Ltd., who with Spokane associates recently purchased the Bayonne group, has made an examination of the property. He states that only lack of transportation has prevented the Bayonne from becoming one of the leading gold mines of the Province. Three shifts are employed in driving a tunnel to cut the orebody at depth, and it is expected that by next spring the mine will be ready for a mill.

Rosland.—Eight lessees have struck a fabulously rich shoot of ore above No. 3 level in the I. X. L. mine, and 1704 lb. of ore sent to the Trail smelter gave a return of 156.48 oz. of gold. A raise has been put up for about 25 ft. on the shoot and a winze sunk about the same depth. The return is equal to about \$1.90 per pound. Some 20 tons of cullings that probably will run \$125 per ton have been mined. Similar ore is still showing at the top of the raise and the bottom of the winze. The I. X. L. is owned by John S. Baker, of Tacoma.

Trail.—Curtailement of operations at the Sullivan mine is reflected in the ore-receipts at the smelter for the week ended October 14, only 3185 tons being received. There were three independent shippers. The Consolidated M. & S. Co. recently shipped six cars of spelter to England by way of Panama.

MEXICO

El Oro.—A serious cave occurred between the 11th and 12th levels of the north shaft of the Mexico Mines of El Oro Mining Co. on October 19. Four miners, Rafael Franco, Trinidad Bolanos, Gregorio Martinez, and Crecencia Martinez are entombed below and are believed to be dead. As large a force as possible is being employed in clearing the shaft, but it will require some time to complete the work.

San Juan de Guadalupe.—An effort is being made to complete the spur running from Rivas station to the Calveritas mines to extend it to the foot of Sierra Ramires, when it will tap other rich mining districts. This line was built by Albert Genty for the purpose of transferring the ores from the Calveritas mines to Rivas station on the main line, and the Government is being requested to assist in extending it.

Louis Zuberia, an attorney resident of San Juan de Guadalupe and owner of a number of rich mines in this region, has re-located the old Solomon mine in the Reyes district. This property was recently forfeited by non-payment of taxes. It was formerly owned by Charles Mosler, who died a few years ago at El Paso. A body of high-grade silver-lead carbonates was at one time discovered in this mine which netted the owners over \$20,000 within a short time.

Torreón.—The Asarco smelter, owned by the American Smelting & Refining Co., situated in the Velardeña district about 60 miles west of this city, is preparing to resume operations after being idle for about a year. It is expected that the plant will be running in full blast by the first of November. This plant has three copper- and three lead-furnaces.

Work of enlarging the Torreón smelter, owned by the Cia. Minera de Peñoles, is progressing rapidly and it is expected that the plant will be ready for operation by the first of the

year. The old furnaces are being torn out and replaced with others of larger capacity. The number will be the same as before—eight lead and one copper.

ONTARIO

Cobalt.—The improvement in silver-mining conditions is shown by the substantial increase in the number of men employed in the industry, as compared with the earlier months of the year. Fewer than 700 men were on the pay-rolls last February, whereas now there are over 1000 employed. Silver production is now maintained at a rate of about 800,000 oz. per month, as compared with about 600,000 oz. a few months ago.

The ore-shoot on the 530-ft. level of the Violet has been opened for 175 ft. with both faces in ore of a good grade. A winze is being put down 50 ft. on the vein, which will be drifted on at that depth.

Kirkland Lake.—The Lake Shore Mines, Ltd., has declared a dividend of 2%, amounting to \$40,000, payable on November 10 to shareholders of record on November 1. During September, 1622 tons of ore netting \$25.23 per ton was milled.

At the Teek-Hughes the big lens developed on the 4th level close to the Lake Shore boundary has been reached on the 5th level, where it shows increased enrichment, some of the ore extracted being stated to run as high as \$60 per ton.—An electrically-driven plant has been installed on the Sylvanite and the first work undertaken will be the sinking of a 3-compartment shaft down to the 200 or 300-ft. level.

Porcupine.—The Dome Mines has issued a statement covering operations for the six months ending September 30, showing operating earnings of \$432,137, and other income, \$81,725, making a total of \$513,863. Deductions of \$369,712 for taxes, depreciation of plant, and depletion of mine left a total profit amounting to \$144,151.—The occurrence of carbon in some of the ore found in the lower levels of the McIntyre has occasioned serious difficulties in connection with its treatment. Various solutions of the metallurgical problem presented have been attempted, and it is now believed that a process has been developed that can be successfully applied.

South Lorrain.—The ore-shoot recently cut at the Keeley mine has been found to have an average width of about 5 in. over a length of 32 ft. as far as opened, and is stated to assay about 4000 oz. of silver per ton.

Obituary

Stuart M. Thorne died at Toronto on October 3 as a result of a heart malady brought on by exposure while on active duty as an officer of the Canadian Engineers during the War. According to the 'Canadian Mining Journal', he was born in 1880, graduated from Toronto university, and later was connected with several mining enterprises in Canada. He was manager, among others, for the Silver Leaf, the Preston East Dome, and the Trethewey mines. In 1915 he resigned from the last named, and went overseas as Lieutenant in the Frist Tunneling Company; while in command of a section of this company, operating at St. Eloi in the Ypres salient, he prepared the largest of the 19 mines that were 'sprung' at the Battle of Messines, on June 7, 1919, winning both the Military Cross and the Croix de Guerre. After his company was merged with the new Battalion of Engineers he served with distinction during the hard fighting of the summer and autumn of 1918, in command of 'D' Company of the Fifth Battalion. In 1919 he returned to Canada with the rank of Major, and resumed the practice of his profession, but his health had been permanently impaired, necessitating his retirement last May.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

T. A. Rickard is at Rolla, Missouri.

John Hays Hammond is at the Fairmont hotel.

A. G. Mackenzie has returned to Salt Lake City from New York.

M. W. Summerhayes has returned to Canada from California.

J. H. Rose has moved from Winthrop, California, to Mina, Nevada.

Edward Thornton has returned to Los Angeles from Hermosillo, Mexico.

Benjamin B. Thayer has returned to New York from Butte, Montana.

Fred V. Burns has moved from Tampico, Mexico, to Houston, Texas.

M. B. Parker has moved from Hollywood to Johannesburg, California.

H. R. Plate has returned to San Francisco from Sheep-ranch, California.

Charles Bocking, manager for the Butte & Superior Mining Co., is in New York.

W. F. Boericke, of Galena, Illinois, has been at Kingman, and is now in San Francisco.

J. I. Brown has changed his address from Seattle, Washington, to Cripple Creek, Colorado.

Erle Huntley has been appointed general manager for the Laloki Copper Mines Co., of Papua.

Horace G. Nichols has returned to Vancouver, B. C., after spending three months in the Liard region.

George D. Blood, manager for the Park-Utah Mining Co. at Park City, is in California for a short holiday.

C. Powell Karr has been appointed a member of the engineering committee of the National Research Council.

R. H. Hawley, superintendent of the leaching-plant of the Utah Copper Co., at Magna, Utah, is at Kansas City, Missouri.

H. C. Carlisle, of Tonopah, Nevada, general superintendent for the Nevada Wonder Mining Co., is at Douglas, Arizona.

Louis A. Wright expects to return to the United States from Obermais, Merano, Italy, by way of New York, about December 1.

O. M. Kuchs sailed from New York on October 26 for Chile to take over the general management of the Andes Copper Mining Co.

John C. Febles has been appointed general superintendent for the Boston & Montana Development Co., at Wise River, Montana.

J. A. Pearce left Berkeley, California, on October 28, to do some metallurgical work for the Cia. del Boleo, at La Paz, Baja California, Mexico.

Alexander McFarland, mine superintendent of the Seoul Mining Co., Korea, will act as general manager for the company during **A. R. Weigall's** absence in the United States.

Walter G. Scott, who has been metallurgist at the Southwest Station of the U. S. Bureau of Mines, has returned to the Inspiration Consolidated Copper Co., at Miami, Arizona.

Howard R. Ward, mining engineer of New York, and **Errol MacBoyle**, of San Francisco, are at Alama, Baja California, Mexico, in the interest of the International Minerals Syndicate.

J. O. Elton has been appointed assistant general manager for the International Smelting Co. He was recently at the Great Falls smelter of the Anaconda Copper Mining Co., as assistant manager.

THE METAL MARKET

METAL PRICES

San Francisco, November 1

Aluminum dust, cents per pound.....	65
Aluminum sheets, cents per pound.....	60
Antimony, cents per pound.....	0
Copper, electrolytic, cents per pound.....	13.25
Lead, pig, cents per pound.....	4.95-5.95

Zinc dust, cents per pound.....	9.00-9.50

EASTERN METAL MARKET

(By wire from New York)

October 31.—Copper is more active and stronger. Lead is quiet and firm. Zinc is dull and lower.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

MEASURES RECOMMENDED BY THE PRESIDENT'S CONFERENCE FOR PERMANENT RECOVERY OF EMPLOYMENT

Recovery of our industry and employment must necessarily be a process of gradual healing of the great economic wounds of the World War. This healing is making distinct progress.

Without attempting the impossible task of assessing the relative weight of different forces, the conference presents the following summary of the more important matters that require constructive and immediate settlement, if recovery in business and permanent employment are to be more expeditiously accomplished.

1. Readjustment of railway-rates to a fairer basis of the relative value of commodities, with special consideration of the rates upon primary commodities, at the same time safeguarding the financial stability of the railways.

2. Speedy completion of the tax bill, with its contemplated reduction of taxes, in order that business now held back pending definite determination may proceed.

3. Definite settlement of tariff legislation, in order that business may determine its future conduct and policies.

4. Settlement of the financial relationships between the Government and the railways, having in mind the immediate necessity for increased maintenance and betterments, making effective increased railway employment and stimulation of general employment, in order that the railways may be prepared for enlarged business as it comes.

5. Limitation of world armament and consequent increase of tranquility and further decrease of the tax burden, not only of the United States but of other countries.

6. Steps looking to the minimizing of fluctuations in exchange, because recovery from the great slump in exports (due to the economic situation in Europe) cannot make substantial progress so long as extravagant daily fluctuations continue in foreign exchange, for no merchant can determine the delivery cost of any international shipment.

7. Definite programs of action that will lead to elimination of waste and more regular employment in seasonal and intermittent industries, notably in the coal industry, in order that the drain upon capital may be lessened and the annual income of workers may be increased.

8. In all the different industries and occupations the rapidity of recovery will depend greatly upon the speed of proportionate adjustment of the inequalities in deflation.

If the buying power of the different elements of the community is to be restored, then these levels must reach nearer a relative plane. For example, the farmer cannot resume his full consuming power and thus give increased employment to the other industries until either his prices increase or until more of the other products and services come into fair balance with his commodities and therefore within the reach of his income.

MONEY AND EXCHANGE

Foreign quotations on November 1 are as follows:

Sterling, dollars: Cable	3.03
Demand	3.03 1/2
Franc, cents: Cable	7.43
Demand	7.45
Lira, cents: Cable	4.11
Demand	0.59
Mark, cents: Cable

Eastern Metal Market

New York, October 26.

Steadiness but not much activity characterizes nearly all the markets.

Demand for copper is moderate with prices steady.

Sales of Straits tin continues and prices are higher.

The lead market is quiet and steady.

There is less activity in the zinc market and quotations are a little lower.

Antimony is weaker.

IRON AND STEEL

The controlling factor in the steel industry now is the expectation by buyers of a reduction in freight-rates, and this has put a damper on buying. The reduction in the price of steel rails by the Steel Corporation has been a factor also.

The Steel Corporation's statement of earnings in the third quarter of the year, like its predecessor, reflected a larger scale of operations than at most independent works; also the benefits of operations in all producing districts and the importance of certain by-products. Net earnings came within \$600,000 of paying the preferred dividend; this was unexpectedly favorable.

In reducing steel rails from \$47 to \$40 per gross ton the Steel Corporation directly points to "reductions in freight-rates and otherwise, together with larger operations" as its dependence for the reduction of its costs. For "larger operations" the railroads must needs release some hundreds of thousands of tons of 1921 rails that have been "frozen" on rail-mill books and to which the reduced price will now apply. In addition, free buying of rails for 1922 is confidently looked for. That independent rail-mills will follow the Steel Corporation's reduction is to be expected.

COPPER

While demand has slackened and the market is by no means as active as it has been, the situation is regarded with satisfaction by most sellers. The electrolytic market is holding well at recently established levels, which is pointed to as a good sign. In some buying movements prices have attained heights which could not later be maintained, much to the detriment of the trade, but in this case this has not taken place. Electrolytic copper for early or November delivery is quoted at 13c., delivered, or 12.75c., New York, though this price was shaded in a few transactions last week. The market seems firm now at this level. Buying for foreign consumption is good, particularly by the Far East and by France and England. Germany is not as active as formerly.

TIN

The past week has again been featured by moderate sales of Straits tin. A peculiarity of these transactions, however, has been that the buying, participated in by both dealers and consumers, has ignored the intermediate positions and confined itself to spot and far-future delivery. The bulk of the business was put through for November-December and December-January shipment from the East with considerable spot business included. The latter may have been due to fears of a railroad strike. Prices, covering the sales referred to, ranged from 28c. for spot to 29c. for far-futures. Yesterday the quotation for spot Straits tin was 28.50c., New York, as compared with 28c. last week. The London market yesterday was quoted at £156 10s. for spot standard, £158 15s. for far-future standard, and £157 per ton for spot Straits or slightly under those a week ago. Prices for American pure tin are reported as close to those of Straits

tin, New York. Arrivals thus far this month have been 1900 tons with 3150 tons reported afloat.

LEAD

Except for an easing in the price situation at St. Louis there is no change in the market. Demand continues satisfactory at 4.70c., New York, but at St. Louis quotations are lower at 4.40 to 4.45c. On the whole the market may be described as steady, quiet, and firm.

ZINC

There is less activity; demand from galvanizers has largely abated. Conditions have caused a slightly easier market in which one or two sellers are offering prime Western at 4.60c., St. Louis, or 5.10c., New York, at which level some business is reported. At any rate it seems that the present light demand can be satisfied by the limited amount thus available. Most producers are either asking more or not quoting.

ANTIMONY

Wholesale lots for early delivery are quoted lower at 4.85c., New York, duty paid, the weakness being ascribed to offerings of lots afloat. Jobbing lots are quoted at 5 to 5.25c.

ALUMINUM

Virgin metal, 98 to 99% pure, is unchanged in an inactive market with 24.50c. f.o.b. plant, asked by the leading producer. The same grade is offered by importers at 17 to 18c., New York, duty paid.

ORES

Tungsten: Conditions are unchanged and quotations are nominal at \$2.75 to \$3.50 per unit, depending on the grade and the quantity.

Molybdenum: Nominal quotations still rule in an inactive market at 48 to 50c. per pound of molybdenum sulphide in regular concentrates.

Manganese: There is no activity with quotations still nominal at 20c. per unit, seaboard, for high-grade foreign ores. Imports in September were 10,402 gross tons bringing the total for the year to October 1 to 336,744 tons against 423,012 tons to October 1, 1920.

Chrome: The market is flat with one seller quoting foreign chrome ores at \$20 to \$26 per net ton, Atlantic ports, nominal, and depending on analysis.

FERRO-ALLOYS

Ferro-manganese: There is no change in the quotations of both British and American products on a basis of \$58.35 per ton, Atlantic seaboard. There is also no demand. Imports in September were 804 tons and the total for the first nine months of this year is 6605 tons against 40,039 tons to October 1, 1920.

Spiegeleisen: The market is devoid of feature with quotations unchanged at \$25 to \$26, furnace, for the 19 to 21% grade.

Ferro-tungsten: The standard domestic alloy is quoted nominal at 40 to 45c. per pound of contained tungsten, f.o.b. plant, while the foreign alloy is quoted at 50c., duty paid, seaboard.

Ferro-silicon: The market for 50% ferro-silicon has recently been broken to \$55 to \$57, delivered, from one small producer.

Ferro-chromium: This market has weakened decidedly until regular 60 to 70% alloy, containing 4 to 6% or 6 to 8% carbon, can be bought as low as 10 to 11c. per pound of contained chromium in wholesale lots.

Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %	60c.
Asbestos (crystalline), according to length of fibre, per ton	\$20 to \$2500
Barite, white and free of iron (crude), per ton	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi	10 to 15
Feldspar, crude, lump, free of iron, per ton	5 to 10
Fluorspar, 85% calcium fluoride, per ton	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton	5 to 10
Graphite, crystalline, per pound	3c. to 7c.
Magnetite, calcined, per ton	25 to 35
Manganese ore, less than 0.75% Fe; less than 6% SiO ₂ , per ton	25 to 30
Mica, according to size, clearness, and cleavage, per pound	1 to 8
Molybdenite, not less than 85% free of copper, per % MoS ₂	8 to 12
Ochre, according to strength, crude, per ton	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton	15 to 18
Talc, lump, white, per ton	7.50 to 10
Tin ore, not less than 60% Sn, per % Sn	4 to 6
Tungsten ore, not less than 35% WO ₃ , per % WO ₃	2.75 to 3.00

T. A. RICKARD, . . . Editor

UNDER 'Discussion' we publish a contribution on the subject of recreation for the workers in mines and factories. The writer, Mr. P. B. McDonald, a graduate of the Michigan College of Mines, is the Assistant Professor of English in the College of Engineering of New York University, and he ought to be able to teach his subject well, judging by his own care and skill in writing. We welcome his letter as an example of scholarly expression and also for its substance, for the subject of a proper kind of recreation for industrial workers is well worthy of serious study.

WARREN NORRIS, a pharmacist at Bisbee, Arizona, recently suggested to the manufacturers of 'Ever-sharp' pencils that copper would be a splendid material to use in the making of their specialty; the idea was accepted at once. The metal is given a simple treatment that enables it to retain its lustre, and an attractive article is the result. It is true that a great many such pencils would be required to consume the existing surplus of copper, but if everyone whose prosperity, like that of Mr. Norris, depends on copper mining could contribute an idea equally good, conditions would improve quickly. The ocean itself is composed of drops of water.

WE are prepared to credit the successful politician with the possession of a large measure of genius; not one man in a thousand can step out of any other walk of life and successfully steer a serene and steady course to political preferment. Generally the real politician is a specialist; his training started, unknown to himself, in grammar-school. Later, the idea of entering politics took shape; if he had the ambition to rise to State or national fame, he studied law—that being the approved preparation for a political career. Perhaps circumstance compelled him to follow his profession at first, but at the same time he schooled himself in the 'art' of politics until the opportunity came for grasping a rung not too far from the bottom of the political ladder. If he had the native ability and had absorbed the innumerable subtleties of the 'game', if he had studied the science of keeping on the right side of the 'peepul' and the technique of getting votes, he climbed rapidly. But occasionally it happens that a man is plucked from some other sphere of life and is dropped suddenly into the political arena; a specific instance of this is the election,

a year ago, of Mr. Samuel S. Arentz as Congressman-at-large from the State of Nevada. Mr. Arentz primarily is a mining engineer, and a successful one, we happen to know; but as a politician he has, or at least had, much to learn. It seems that, some months after his succession to office, he received a bundle of photostats reproduced from the draft of the proposed new Mining Code, drawn by the now well-known committee of engineers at the instance of the Bureau of Mines. It was suggested that, being a new member from one of the leading mining States, he might be glad to introduce a bill incorporating the proposed code. Mr. Arentz, who apparently had mastered one of the first principles of politics—the value of advertising—welcomed the idea and directed his clerk to draw-up, in proper form, the document now known as the Arentz Bill. Not every new Representative is accorded the honor of introducing a bill under his own name within a year after his election; the world would necessarily look upon the well-drawn bill as the child of Mr. Arentz's brain and would pay due homage, irrespective of what his personal views on the measure might be. The Arentz bill went forth; it was published, among other places, in every weekly paper in Nevada; and there it raised a storm of protest among the prospectors and small mine-owners. Recently an indignation meeting was held at Reno, at which the bill was condemned without qualification. Now it should be known that Mr. Arentz's friends regard him as being promising material for United States Senator from Nevada; wherefore this tactical error in introducing the mining bill was most grievous. However, next to the ability to avoid the necessity for making explanations, the ability to make explanations is the politician's greatest asset; so Mr. Arentz writes home to his constituents that he introduced the bill for the reason that he believed that his position as apparent sponsor would enable him most effectively to accomplish its defeat. The explanation, we believe, marks Mr. Arentz as a suitable candidate for Senator.

ADDRESSING the recent convention of the American Mining Congress, Mr. W. J. Loring, the president, in discussing blue-sky legislation, declared: "It is typical of Americans not to want a sure thing. Take away from the public the right to take a risk, and you imperil the progress of the mining industry which has been built by men who were willing to stake all. I am against the idea

of a regulative bureau; it is well intentioned, but wrong". To us it seems that Mr. Loring's reasoning is at fault. His expressed conviction is not the logical result of his premise. The purpose of well-considered blue-sky laws is to see that the public has 'a run for its money'—to prevent unscrupulous promoters from playing a 'sure thing' and taking the money of ignorant but honest speculators, without giving them even a gambler's chance. The miner has always worshipped at the shrine of the Goddess of Fortune. When all the cards are on the table, mining is at best a gamble; when the deck is stacked by dishonest promoters, the outsider is up against a 'sure thing'.

EMPLOYER and employee are certainly at logger-heads when every action on the part of one faction is the object of mistrust and suspicion by the other, and when the correctness of every statement, the truth of which is not obvious, is doubted. The recent history of the wages dispute at the Mount Morgan copper-gold mine in Queensland, Australia, provides a lamentable exhibition of such a spirit. The decline in the price of copper late last year prompted a conference between the general manager and representatives of the various unions, at which it was explained that a resumption of operations would have involved a loss of about £2300 per week. The general manager told the men that the company could not face this with equanimity, and proposed a reduction of 20% in the current rate of wages, and the resumption of work; the delegates' reply suggested referring the matter to the Arbitration Court. A conference was then called, after which the unions proposed that the men should be paid 80% of the existing rates and given deferred-wages certificates for the remaining 20%, the latter to represent monies that would be payable as soon as the company was earning a profit. The general manager replied that the suggestion offered no solution of the difficulty, for it did not reduce the cost of operations; the company proposed, as an alternative, a sliding scale of wages, based on the price of metals; this was rejected by the unions. At this stage it was evident that no agreement could be reached without what is commonly known as a 'show-down'; for the men were suspicious of the good faith and truthfulness of their employers. At the instigation of the unions an application was filed with the Industrial Court for an investigation of the figures given by the company as to the cost of producing copper. An official order was then made to a firm of accountants to examine the books, to prepare the necessary schedules, and to report to the Court. In due course the accountants' finding was made; it showed that, under the then existing rate of wages, the price paid for copper would have to be over £92 per ton if the cost of production was not to exceed the receipts. The verdict, instead of helping the case for the unions, showed that the company had been unwisely generous in its terms; for had its offer (of a 20% reduction in wages) been accepted, operations could only have been continued at a loss to the stockholders. This

example is one of many that may be cited to prove that the employee often maintains an attitude of unfounded mistrust toward his employer. The friction that results is one of the principal causes of the hindered settlement of industrial disputes.

RESearch is a word that has been subjected to the usual maltreatment at the hands of many who are not qualified to undertake the work involved in a search for facts and principles that is prolonged and diligent, the result of which is a scientific achievement. At a recent meeting of the American Society for Steel Testing, Mr. E. P. Hyde divided such work into scientific research and engineering research. The former may be pure or applied; it may be further divided into frontier research and co-operative research. Applied scientific research is an industrial effort. Under the heading of 'engineering', Mr. Hyde details engineering research and engineering practice. Our contemporary 'Chemical and Metallurgical Engineering' makes some admirable comments on the subject in recent issues; it protests that all five classes in Mr. Hyde's outline cannot be designated as varieties of research. To this we agree. Scientific research is the foundation of all advance; it heralds the discovery of a new and hitherto unknown fact. The scientist must be a free agent; various instrumentalities are now bestirring themselves to encourage him in his work, and they should bear this fact in mind. They should see that the research professor receives a salary that will enable him to live without grinding economy; he should be relieved of petty administrative details, and then left alone to make his discoveries; his researches are needed to furnish the fundamental basis of scientific and engineering progress. Then comes the examination from all angles, the devising of applications, and the testing of materials, the last-named being merely experimentation. Research, says our contemporary, may be likened to a voyage of discovery. Land is reached; then comes the task of making maps, followed by the building of roads; the fields are cultivated and the natural resources are exploited; lastly, when adequate settlement is an accomplished fact, comes the necessity for crop rotation and for fertilization. It is a far cry from the trackless forest to the truck-garden. We agree. The sloppy and occasionally dishonest use of key-words is becoming too common. Research is an indication of painstaking effort to add to the sum of human knowledge; but the term is often usurped by the hit-or-miss experimenter, or by the investigator whose 'researches', as indicated by voluminous writings, fail to carry conviction or to indicate the possession of a creative spirit of invention.

THE metric system has a staunch supporter in Mr. Huntington Adams, whose connection with the introduction, in Mexico, of an important development in cyanidation—continuous agitation in Pachuca vats—will be recalled. Mr. Adams, whose letter on the introduction into the United States of the metric system of weights and measures appears on another page of this issue,

speaks from a personal engineering experience in various countries where the system is or is not compulsory. Such opinions are of value, if only to combat the anti metric propaganda that is so insular in its viewpoint. Mr. Adams gives an excellent summary of the conditions throughout the world in so far as the prospect of uniformity in this respect is concerned; he emphasizes the tendency on the part of those of British race to discountenance any change from long-established methods and customs, citing the riots that occurred in London in 1752 because the Government desired to correct the error of the old Gregorian calendar by the deletion of 11 days in the month of September. We welcome further comment on this most important question of conformity to a world's standard of weights and measures, as important to ourselves as to our descendants. The opponents to the introduction of the metric system harp on the cost of the change to the manufacturer, which suggests that the propaganda is being subsidized in favor of a group or groups. However, we understand that manufacturers are exempt from the provisions of the bill now before Congress; they are at liberty to change their standards to that of the metric system if they desire; there is no compulsion about it. The initiative will doubtless be taken by a few progressive firms as soon as the proposed legislation becomes law, the result being that there will be an early evidence in their works and factories of an increase in efficiency and a saving in labor. This will place those manufacturers at an advantage; the general adoption of the metric system will then be inevitable. Industrial corporations balk at the expense, which should be nominal in most cases; such expenditure is purely optional, but having once been made it will, we believe, prove to have been a sound and profitable investment. Other contributions to the discussion columns in this issue include Mr. S. A. Kuapp's views on the restoration of bimetallism. He argues that the enactment of a Free Coinage Act, making silver one-sixteenth the value of gold, would restore the metal to parity throughout the world, especially if joint action to this effect could be taken with Canada and Mexico. Mr. Samuel H. Dolbear writes from New York on the respective characteristics of wetting and amalgamation. Mr. Edgar Hall discusses the element of time in cyanidation, quoting an instance in which this factor was disregarded when interpreting experimental results. Various explanations have followed the almost inevitable failure to treat silver ore by a gravity leaching process, but the fact remains that all-sliming is essential if an adequate extraction of the metal is to be expected.

Osmiridium

With the decrease in the production of gold, attention is being paid to the value and utility of the rarer metals. Among these may be mentioned osmium and iridium, or their natural alloy, osmiridium, which is used, in minute individual quantities, for fountain-pen points and for the bearings of delicate and sensitive instruments.

Iridium was being sold for as high as \$100 per ounce late in 1919; it is now worth about \$165 per ounce. A few hundred ounces of this metal is recovered annually during the refining of gold bullion, nickel, and copper in the United States; a little more of osmiridium is obtained from the same source. Imports of the latter into this country increased from 259 ounces in 1917 to 427 ounces in 1918, 1374 ounces in 1919, and 4473 ounces in 1920. The precious alloy has been found in the concentrate that remains after 'cleaning up' the sluices that are used in hydraulic mines; the amount recovered is small, so the production of osmiridium from this source is negligible. More recently, however, attention has been paid to the occurrence of the alloy in Papua, formerly British New Guinea. There it occurs in association with gold, as well as in the free state; it was formerly discarded, as it was also in Tasmania, where the miners looked upon it as a nuisance. Their confreres in Papua, whose 'gold' contained osmiridium, found, on selling their bullion, that they were penalized. The more precious alloy was classed among the base metals, the mint authorities objecting to its presence in the bullion because of the resultant defacement of the dies used in coining.

When free, osmiridium occurs in a flaky form and also in shot-like granules. Recently the 'Daily Mail' described the arrival in London from Papua of a small consignment of the alloy, weighing about 2½ pounds, which was eagerly bought for £1200 by the representative of an American firm. The story of the first discovery of osmiridium is also recounted. It appears that a small group of prospectors, who were washing gravel in one of the river-beds, noticed a bluish-gray metallic substance in the pan, but, in their eagerness to find the yellow metal, they threw it away as valueless. On returning to the settlement they mentioned the occurrence to a mining engineer, who exclaimed, "It must be osmiridium". The next morning the party returned to the spot, only to find that the tropic rains and the swollen river had washed most of it away. What remained was carefully recovered, cleaned, and dispatched to London, where it found a ready sale at a fabulous price. New Guinea consists of virgin territory, almost unscratched by the prospector, and undeveloped by the engineer. It is possible that it may become an important source of precious and rare metals.

Second-Hand Equipment

Many maintain that it is an ill wind that blows nobody any good. In a report upon the low-grade mines on the Witwatersrand, the Government commission that was appointed to study the question of economical operation commented on the difficulty and expense of securing machinery for new mines, and stated that the cessation of operations at some of the low-grade properties would enable mining companies to secure suitable equipment at reasonable prices and promptly. Mr. R. C. Atkinson, in his inaugural address before the South African Institute of Engineers, gives some pertinent arguments

against the use of second-hand machinery, and draws attention to many points of interest that usually escape the consideration of the buyer. Those who have had experience in the purchase, dismantling, transport, and re-erection of such equipment will probably agree with him that the idea is not so attractive as would appear at first sight. The plant, having been in operation for a number of years, probably will possess mechanical and metallurgical features that have been superseded; such must be modified if the latest practice is to be adopted. It is conceivable that the alterations involved may entail the re-arrangement of the various units; this, in turn, will affect the network of connecting links, such as classifiers, launders, pipes, pumps, and elevators. In other words, the plant cannot be dismantled and re-erected as before, piece by piece, each fitting in its place, as some imagine. In order to obtain the highest extraction compatible with low costs, such equipment can only be used in conjunction with more up-to-date units, appliances, and methods. The original drawings of plant that has been in operation for some time, even if obtainable, are of little use in regard to an alternative arrangement of units; if, as happens not infrequently, alterations have been made, or should departures have been adopted from practice indicated by the drawings furnished when the plant was first put in commission, which are not shown therein, the matter is complicated still further. Thus the work in the drawing-office may exceed that required for a new plant. In the latter case it is merely a matter of referring to the existing drawings and to data of recent equipment in order to decide what alterations or improvements are necessary to modernize the installation. In the case of the second-hand mill, this becomes an operation that is difficult in proportion to the number of years that have elapsed since the plant was designed. Thus it is that the preliminary work, before re-erection is commenced, is considerable and involved; little saving, if any, is effected by disregarding the advantages of new equipment. Furthermore, the dismantling of second-hand machinery may, and often does, reveal defects that could not be discerned by such inspection as usually is permitted before purchase; these, coupled with the losses and breakages that are inevitable, must be taken into account; the largest item is invariably on account of repairs and renewals, due to such defects. In the case of a mill, a careful examination before purchase will reveal, more or less, what expenditure is necessary to re-condition the plant; and a close approximation can usually be made as to the amount required. New foundations must be provided, however; and these will cost as much as would new equipment. But units such as tanks, vats, pumps, compressors, boilers, condensers, and concentrators, which cannot be examined internally before the sale, are often a disappointment if purchased second-hand. Tanks and vats, of which the parts above ground are in good condition, may require new bottoms; pumps may need new spindles and new liners, or the shells may be badly corroded or worn; boilers may need new tubes, the cylinders of engines or compressors often

require re-boring; and new pistons, piston-rings, and other parts must be purchased or manufactured. By this time the original estimate of saving may have been reduced to insignificant proportions, or the investment may be considered as thoroughly unsatisfactory. Moreover, the maintenance costs of a re-conditioned plant are often much higher than is the case with a new plant. We are inclined to agree with Mr. Atkinson that the acquisition of second-hand equipment is seldom good business.

Mining in Russia

As our readers are aware, an effort has been made recently on the part of the Russo-Asiatic Corporation, a British mining company with which several distinguished American mining engineers are connected, to resume operations at its properties in Siberia. The negotiations were conducted for the company by Mr. Leslie Urquhart, the chairman, and for the Soviet government by Mr. Leonid B. Krassin, of the Russian Trade Delegation, an agency established for the purpose of facilitating the resumption of foreign enterprise in Russia. After lengthy negotiations, conducted partly in London and partly in Moscow, it has been found impossible to arrive at a settlement. We publish Mr. Urquhart's letter to the shareholders, as well as his letter to Mr. Krassin, both being printed verbatim because they are documents of great interest, as throwing a lurid light on the real economic plight of Russia at this time; it seems to us that the facts in this case are worth more than half a dozen magazine articles by economists and sentimentalists. The mining profession in the United States is interested in the matter because many of our engineers are connected, or have been connected, with Russian mining enterprises. Among those in the employ of the Russo-Asiatic Corporation are Messrs. R. Gilman Brown, H. H. Knox, T. J. Jones, D. P. Mitchell, and A. W. Stiekney. Besides these, Messrs. H. C. Hoover, Theodore J. Hoover, A. C. Beatty, and J. Power Hutchins have been interested in important operations in Siberia. Therefore the prospects of a resumption of profitable activity are of more than academic or sociologic interest. Mr. Urquhart conducted his part of the negotiations in a tactful and amicable manner, we feel sure, for he has a high reputation as an unofficial diplomat, having spent a part of his early life in Russia, so that he speaks the language well and knows the people intimately. Mr. Krassin, likewise, seems to have done his best, but the chaos of social muddle and political mismanagement has proved too much for both. No further comment is necessary; we invite our readers to study the evidence. It remains only to note the pathetic fact that the laborers and other employees on the Russo-Asiatic properties, which include mines, smelters, and factories, were anxiously hoping that a resumption of work would ensue; many of them sent personal messages of goodwill to Mr. Urquhart. It is evident that the action of the Soviet authorities will be a blow to that restoration of industry upon which the salvation of Russia depends.

DISCUSSION

The Problem of Recreation

The Editor:

Sir—One of the great problems in industry today, though perhaps it is not clearly recognized as such, is that of recreation. The men and women working in the busy factories and mines of our land need recreation. Our forefathers did not require recreation as such because their work was varied and leisurely; it was something of an adventure in itself. Today work in industry has been standardized, subdivided, and mechanized. One man feeds a machine, another inspects bolt-ends, another addresses packages. Constantly the operations are being performed at higher pressure and at greater nervous strain. Constantly the hours are being shortened, leaving more time for recreation. But the question is, how shall the worker find recreation such that he will return to his bench or desk refreshed and content? The famous Taylor of scientific-management reform proved by indubitable tests that more hard work can be accomplished if the workman has suitable rest at short intervals. How much more important is it that proper recreation be available for the time off shift. What recreation then is possible?

In the great industrial districts of Germany the worker from factory or mine takes his family in the evening to a beer-garden, where for the price of a stein or two of beer for each they see and are seen, converse, and are entertained. In France there are the boulevards with their little tables where a few cents spent for wine or beer permits one to sit and watch the world wag by. Baedeker says of urban Frenchmen, "most of them spend their evenings at the cafés, where they take coffee, liqueurs, or beer, meet their friends, read the newspapers, or play billiards or cards". The most popular amusement in the United States, particularly since the coming of prohibition, is the 'movie'. It is popular also in British countries—though sports and the public-house contribute to their entertainment. The darkened and speechless atmosphere of a cinema-theatre seems especially to suit the Anglo-Saxon: perhaps the vicarious methods of adventure agree with his puritanical instincts.

In America the automobile is a coveted means of recreation, but as a national palliative it has serious limitations. Many workers cannot afford it; many do not care for recreation that consists in driving a machine; and, after the novelty has worn off, riding to a destination and then returning loses much of its zest. Possibly when travel in the air has been perfected and

cheapened, flying will become the great recreation of civilized man, particularly if small airplanes can be manipulated without too much effort and attention, much as a sea-gull soars and glides above the dust of mundane things.

There remains the recreation of art, by which is meant literature, music, and the fine arts generally. William Morris suggested that the true function of art is to allay restlessness and discontent. Ruskin tried to put the principle into practice by establishing an art-gallery in the slums of London. The idea is excellent in theory, but has not worked well in practice, especially among the American or British peoples. Theodore Roosevelt said flatly that Americans are inartistic, and he was probably right. Who can imagine grand opera, or poetry, or paintings allaying discontent in a factory-town in New Jersey or a mining-camp in Arizona? The result would be something like Carol Kennicott's attempt to brighten up Gopher Prairie!

When all is said and done, the nearest approach to true recreation in America was the much-maligned saloon. It was so seriously abused by 'treating' that few are sorry that it is gone. But it was our nearest approach to the beer-garden of the German or the boulevard café of the French; it was, in a way, the poor man's club—a place where the worker could resort and chat with his fellow without feeling ill at ease or patronized. After all, it is chatting with one's fellows that makes real recreation; exchanging ideas by talking marks human beings apart from other animals. The so-called community-centres and welfare-stations are misguided attempts to replace the saloon; they approach the problem from the wrong angle. It is perhaps difficult to explain why a 'community-centre' does not attract and interest the solid backbone of an industrial centre to the extent that a saloon used to, or to the extent that the beer-garden and café interest the European. There is an atmosphere of artificiality or futility or condescension about such a place that bores the average worker. A meeting-place, to be a real centre of sociability, must be casual yet full of possibilities; it should be a meeting-place indirectly while ostensibly something else, and there should be many of them in a town, so that, if a man doesn't like one, he can try another.

Much of the discontent and labor trouble of the past several years in this country has come from the worker having no proper recreation. He found himself in the hours off duty with nothing to do except grumble and agitate. If the nation can evolve a satisfactory substitute for the saloon, meeting-places where the population

can congregate without self-consciousness or boredom, one of the serious problems of the future will be solved. For it is not too much to say that, of the great industrial nations of today, those which furnish satisfying recreation to their workers are going to surpass those which do not. Certainly man does not live by work alone; he must have relaxation and sociability; and as work becomes sterner and more intense the need of recreation becomes correspondingly greater.

P. B. McDONALD.

New York, October 15.

Monetization of Silver

The Editor:

Sir—In a recently published article, Mr. George W. Hinman presents and argues for the London 'Statist' plan of restoring currency, exchanges, and trade. He urges:

"That the depreciated currencies of France, Italy, Germany, Belgium, and England be made convertible into gold at their present dollar value."

This amounts to repudiation to a certain extent of the obligations of these governments, and it is manifestly unfair to establish permanently a reduction in the value of the circulating medium of those peoples because in time their currencies will probably recover their standing. The exchange rate as quoted is an arbitrary rate, changeable from day to day, and based upon speculative ideas as to whether the people can recover and pay, or not.

What I am about to say may not suit the views of many people, but thinking people who have watched the trend of events, since the final repudiation of bi-metalism in the United States, will, I think, at least give the matter careful consideration. It is not a new idea; it has simply remained dormant, but it is time that it should be given expression.

A glance at the exchange rates shows that those of India and China (where silver is the money of the people) are depreciated (in terms of gold), and this depreciation is practically the depreciation in the bullion-value of the silver in the rupee, in India, and the small silver bars used as currency in China. In all the European countries there is a certain amount of silver coin in circulation (much of it, however, at present, buried in the ground for safe-keeping). This as well, under the present laws and conditions, is depreciated (in terms of gold) to its bullion-value.

Silver is the money of more than three-fourths of the people of the earth, and remains as such, notwithstanding the arbitrary establishment of the single gold standard, and the demonetization of silver in the United States, and some few other countries. It is in demand by foreign countries as shown by the recent advance in the price of silver bullion produced outside the United States. Since silver was demonetized by the United States, or during the period 1894 to 1920, statistics show that about 5,000,000,000 fine ounces of silver has been produced in the

world, all of which has gone into use; a small proportion has gone into the arts, but by far the greater portion has gone into circulation as money in India, China, Japan, and the other foreign countries, the United States not having been a purchaser except for small amounts.

The principal silver-producing countries are the United States, Canada, and Mexico, while practically all the countries are users of silver as money, while in India and China it constitutes the great bulk of the circulating medium. The restoration of silver to its proper basis as money at the ratio of 16:1 with gold (or at the rate of \$1.2929 per ounce), as it existed for many years prior to its arbitrary demonetization, would have the effect of bringing up the exchange-value of the currency of India and China to par, and would practically double the present value of the silver coin circulating in foreign countries, and by restoring it as a money metal would broaden the coin basis, behind the paper currency of those countries, and thus tend, in a measure, to increase the value of the promises to pay of those countries, and assist in stabilizing the various rates of exchange. It cannot be expected to restore entirely the currency of those countries that have issued paper currency far in excess of their ability to pay, but what silver they have, together with the gold they have, or may obtain, would form a nucleus upon which they could establish a limited credit, and give them a sound economic basis upon which to build, and gradually retire their excess paper currency.

The enactment of a Free Coinage Act by the United States on a basis of 16:1, and making it legal tender for all purposes, public and private, would restore it to par all over the world, or if considered preferable, joint action of similar character could doubtless be had between the United States, Canada, and Mexico, with the same effect. The principal objector will probably be England, who has desired, and probably now desires cheap silver to settle her exchanges in England and China, but the beneficial effect upon the exchanges of all countries, including her own, would probably outweigh her objection, and it would probably have a good effect in settling the unrest in India. All other countries would doubtless welcome the opportunity.

The Senators from Nevada, (Jones, Stewart, and Newlands), W. J. Bryan, and the leaders in the fight against the demonetization of silver from 1876 to 1893, were correct in their position and claims, and time has proved such to be the case—the opportunity now offers to restore silver to its proper place as a money metal, and at the same time, and by this means, assist these other peoples in their struggle to get on a solid footing.

Gold and silver together were for ages the money of the world. More than one-half of the hard money of the world was depreciated in value when silver was discredited as money by unwise and uneconomic legislation. All forms of paper money are but promises to pay hard money. Restore silver to its proper place, and you double the hard-money basis behind the currency. The only country that benefited by the depreciation of silver was

England (all others, including her colonies, were injured); for by settling her exchanges with India and China with depreciated silver, she could in a measure control and lower the price of the wheat and cotton she required, regardless of the law of supply and demand, and to the detriment of the producers of these staples in other countries.

An International Court, to settle disputes between nations, backed by an international agreement, to enforce its rulings, binding upon the various nations, after ratification by the people of the separate nations, coupled with the adoption of the restoration of silver, and a consequent doubling of the hard money of redemption of the world, would go a long way to prevent future wars, reduce taxation, and restore the people of the world to peace, and to a sound economic basis.

Wetting and Amalgamation

The Editor:

Sir—An interesting view of the function of oil in flotation has recently been advanced by one of the examiners in the U. S. Patent Office, which prompts me to ask the opinions of your readers on the question. The examiner takes the view that the selective preferance of quicksilver for gold is analagous to the selective preference of oil for metalliferous substances. To me the functions of oil toward metallic particles in an ore are quite different from those of quicksilver toward gold. Amalgam is entirely different from flotation concentrate, or, to make the analogy closer, from the concentrate that collects on greased belts, as in the patents of Haultain, Wolf, and others.

Gold amalgam in an excess of quicksilver is either a true solution as an alloy dissolved in quicksilver, as gold in a true solution, or it is an alloy of variable chemical structure, according to the amount of quicksilver available for the structure. Such a condition would not seem to be parallel with that found in a mechanical mixture of oil and sulphides, or oil and metal particles.

Metric Weights and Measures

The Editor:

Sir—I note with interest your editorial on the subject of the introduction of a metric system of weights and measures. I have read, also, the papers on the same subject by W. R. Ingalls and Howard Richards Jr. in the May issue of 'Mining & Metallurgy'. I think that your reasoning is excellent and foreefnl, and I particularly like your suggestion that the matter be considered in the light of future welfare rather than of present inconvenience. The possibility of world uniformity is also most important. Mr. Ingalls, who writes as if he wished to win his case regardless of its merits, tries to settle the

matter with the statement that, "considering the Indo-European race alone, there is a much larger part of the population that does not use the metric system than does; and their nations are far superior in industrial development . . ." The accuracy of this statement depends, so far as numbers are concerned, upon the 'Indo' part of the term Indo-European; for it includes against the metric system (in a negative sense) the 314,852,881 people of India who, according to the census of 1911, do not speak English or other European tongue. The 'Statesman's Year Book' for 1920 gives the population of India, according to the 1911 census, as 315,156,396, of whom 303,515 spoke English and 122,919 were British.

All the countries of Europe, except Great Britain, Russia, and that part of Turkey which still remains, use the metric system and make its use obligatory by law. I have been told by Russians that all scientific and industrial work there was done entirely in the metric system in pre-bolshevik days; most of us remember the fights for the 183- and 203-Metre hills outside Port Arthur during the Russo-Japanese war of 1904-1905. Moreover, as stated in the year-book referred to, Poland, Lithuania, Latvia, and Finland have all made the metric system official and obligatory since they separated from Russia after the War. Japan, which for some time has used the metric system in conjunction with its old systems, has this year adopted regulations making the use of the new system obligatory; the change will be gradual.

One of the favorite arguments of those in this country who are against the adoption of the metric system has been that in Mexico and in Latin America generally its use has not been universal, although it was adopted officially many years ago. The idea has been to imply that other measures might have been found to be more convenient. On the contrary, the metric system is the only one that is taught in schools and colleges, and it is used exclusively in all scientific work and in engineering by the natives of those countries, as well as in all official records. The use of any other system at all has been because of the demand of foreign trade with English-speaking people, because of industrial undertakings that are controlled by them, or as the result of the adherence to the relics of antiquated systems from which the uneducated people in remote districts have not yet been weaned. If the English-speaking peoples did not form so important a part of the foreign trade of those countries, measures other than metric would soon disappear, as they have over all those parts of Europe where the metric system has been long established.

The population of the European countries that use the metric system entirely (excluding Russia) totals about 300,000,000. The Latin-Americans who use it, except when they are obliged to do otherwise to please foreign clients, number about 85,000,000; the Japanese, 60,000,000. On the other side of the slate we have a total of 65,000,000 Britons (including those in all British colonies but excluding subjugated populations of alien race), and 105,000,000 Americans, who use variants of the English system or systems; so that a total of 450,000,000 civilized

people use the metric system against 175,000,000 who use the English system. It is not a fair comparison, however, to count the number of people that use one system against those that use the other; for in the one case the system used is the relic of primitive and unscientifically developed units, for the continuance of which there is no apparent reason except that they have been handed down from generation to generation; we have learnt them, or have tried to, in our childhood. In the other case there has been a deliberate adoption of a scientific method, by peoples to whom it was at first strange, and who had to discard the antiquated systems in former use that were similar to, and, in general, as good as the English one.

The 22 separate nations of Europe, together with the 19 of Latin-America and Japan who have adopted the metric system, presumably have done so because they considered it superior; its adoption was worth more than the inconvenience that would result in making the change. In the case of Latin-America, I confess that the adoption of the system may have been due, in part, to an admiration of, and willingness to follow, French lines of thought. However, this cannot be given as the reason in such cases as Germany, Holland, the Scandinavian countries, or Japan. No self-governing people has ever changed from the metric system to any other, nor is there any reason to suppose that one ever will. It will therefore seem that the hope of securing world-wide uniformity rests on the adoption, by all, of the system that progressive nations have adopted—nations who wished to improve on antiquated and unscientific methods. Moreover, the metric system is so generally used already that if the United States were to make its adoption legally compulsory it seems unlikely that the British would allow much time to pass before they followed suit; world-wide uniformity among civilized peoples would then be an accomplished fact.

There is no need to enlarge on the matter of the greater convenience of the metric system, but it is pertinent to remark that, to the engineer, it is not merely its decimal arrangement that is attractive, but the almost ideal inter-relationship of units of length, volume, weight, and power, which require little effort to keep in mind, and little or no calculation or the use of tables to apply. If the law were passed, making the metric system the only legal one, that alone would effect the change. Farmers might continue to think in bushels until they found it more convenient to think in the hectolitres in which they would sell and ship; storekeepers might sell merchandise by the foot, so long as it was billed in metres. Moreover, the dimensions of articles would not have to be changed, except in so far as the manufacturers wished to change them; they would merely be given in other terms. I can see no necessity for any direct expense except for paper, printing ink, and clerical work. The individual would have to become accustomed to think in the new units, and many to whom the metric system is new are frightened at the prospect, but we have heard little about the diffi-

culty, if any, experienced by others who have made the change; and surely we would have done so, had it amounted to anything.

I am not sanguine about the early adoption of the metric system in the United States, whatever its merits; there seems to be a strong prejudice among those of British race against any change in things they are accustomed to; this is shown by the rioting that took place in London in 1752, when the Government deleted 11 days from September, in order to correct the obvious errors in the old Gregorian calendar. This country is not being run as it was in 1787, and I hazard the guess that, if the decimal system of currency had not been adopted then, Mr. Ingalls and his supporters would be arguing as to the superiority of a system of pounds, shillings, and pence, as some still do in England. Incidentally, I consider that the advantages of a decimal system of currency are not nearly so great over the sterling divisions as are those of the metric system over the non-related systems of length, area, volume, and weight. I do believe, however, that sooner or later the change will have to be made—that some day our merchants and manufacturers will understand that it is to their ultimate advantage to adopt a time-saving system and to conform to the units used by the majority of civilized people. Obviously, the sooner the change is made, the easier it will be to make it.

Time Element in Cyanidation

The Editor:

Sir—In your editorial in the issue of July 2 you omitted to give, among common sources of error in testing ore for cyaniding, the element of time. That is most important, particularly where silver is concerned. About 20 years ago, when the cyaniding of silver ore was little understood, I built a mill to treat an ore averaging 13 oz. silver and 3 dwt. gold per ton. Over a year was spent in experiments, and, to make sure, a five-stamp mill was hired, and vats were built to treat the ore in two-ton lots, exactly as it would be treated in the mill. Results showed good extraction from sand and slime, so the big mill was erected with confidence.

To our surprise, although the slime gave a good extraction, we failed to get the silver out of the sand. Of course we invented all sorts of explanations, and it was some time before we found that we had overlooked the time factor, and that the ore required about four times as long to treat as we had allowed for. Our experimental work was right, but we forgot that, in the small mill, we did not work continuously, but only on the day-shift, and we left off from noon on Saturdays to Monday mornings. During the time we were resting the ore was soaking, and altogether it had the long time necessary to give a complete extraction; so we had to enlarge the vats.

THE CALIFORNIA RAND SILVER MINE, LOOKING TOWARD RANDSBURG

The California Rand Silver Mine—I

The Story of the Enterprise

By Arthur B. Parsons

The story of the California Rand mine invites, and indeed deserves, less prosaic treatment than it necessarily must receive in this article. An interesting chapter on the subject might be entitled 'From grubstake to affluence in 90 days'; another might be 'Miss Edith Coons: a prospector at heart'; a philosopher would be tempted to discuss the 'Psychology of Prosperity' if he were to visit Randsburg today; and an excellent sermon for the present-day prospector might have as its text 'The California Rand mine; a bonanza that lay undeveloped for 25 years, within a hundred feet of a good road in the heart of a well-known mining district'. However, I shall endeavor to relate the story briefly, starting with the first discovery in the Randsburg district in 1893.

The accompanying map of California shows that the Randsburg district is situated almost on the dividing line between Kern and San Bernardino counties. Railroad communication is by way of Mojave, a station on both the Santa Fe and the Southern Pacific railroads; Bakersfield is the nearest city of importance, and all the large stockholders of the company owning the California Rand mine are residents either of Bakersfield or of Randsburg. Incidentally, I may remark that, up to September 1, 1921, they had received almost exactly \$1,000,000 in dividends, the first distribution having been made on September 10, 1919, just five months from the day the original discoverers chanced to pick up on the hillside a

piece of loose rock that one of them recognized as being hornsilver. In a little more than two years there has been shipped 22,000 tons of ore that netted, after payment of high freight and smelter charges, \$1,729,170.80. The gross value of the silver and gold in the ore averaged more than \$100 per ton.

The year 1893 was particularly dry, so that farming in the valley above Mojave languished, a circumstance that stimulated prospecting for placer gold in the hills, where a number of productive claims were worked. These included the Goler, Summit, Red Rock, El Paso, Last Chance, and Black Mountain, all of which proved profitable to their owners. One of the partnerships that was created for the purpose of mining gold consisted of Frederick M. Moores, formerly of the 'Brooklyn Eagle'; Charles A. Bureham, a teamster; and John Singleton, a hard-rock miner; they traced the alluvial gold to its source on Olympus mountain, where they staked 11 lode claims and organized the Rand Mining Co., the name being changed a little later to the Yellow Aster. The total production from the Yellow Aster has been \$9,000,000 in gold, and in late years it has paid dividends to the amount of \$1,250,000. Following the discovery made by Moores and his partners, hundreds of claims were staked and the town of Randsburg grew at the foot of Olympus mountain. There seemed to be plenty of gold near the surface, and the town prospered. In 1894 the Garlock stamp and amalgamation mill was

built at a point 12 miles below Randsburg; later a mill was built at Barstow on the main line of the Santa Fe railroad. Both these plants received high-grade gold ore from the Yellow Aster and from other mines; much of the ore returned \$600 to \$1000 per ton by straight amalgamation.

Tradition has it that outside capital was not welcomed; the reason for this attitude of exclusion is explained by the following incident, the accuracy of which is readily vouched for by 'old-timers' at Randsburg. It seems that George Kinyon and his two sons, Will and John, owned the Good Hope group of claims, from which they were mining rich ore as rapidly as they needed money. A group of capitalists at Los Angeles was desirous of doing some speculating in gold mining, and, without any extensive preliminaries, began negotiation for the Good Hope claim. But Messrs. Kinyon declined to show any particular interest. Someone suggested privately to the representatives of the capitalists that the Kinyons distrusted banks and paper money, whereupon a wire was sent from Los Angeles saying: "Am placing \$150,000 gold coin in Wells Fargo office subject your order for Good Hope mine". In behalf of his sons and himself, the elder Kinyon, although he had full confidence in the Wells Fargo Express company, declined the offer on the ground that after the education of the children and the comfort of the womenfolk had been provided for, there would be only about \$30,000 apiece for the father and two sons. "This", he said, "is so little that if we should accept it there would be a foot-race to see who could go broke first so as to borrow from the others." When one visits Randsburg he will probably be told this story by way of explanation of the lack of deeper development of the mines.

In 1895 the Yellow Aster company erected a 30-stamp mill, and in 1900, when the railroad was extended to Johannesburg, two miles distant, a 100-stamp mill was built. To supply this plant the mine was opened as a huge glory-hole and a large volume of low-grade ore was milled. The rising cost of labor and supplies, however, caused the suspension of operations in 1916, although I am told that part of the mill has been in regular operation on ore mined by sundry lessees since my visit to Randsburg last August. It is interesting to note that Dr. Rose L. Bureham, the widow of Charles A. Bureham, is now secretary for, and a prominent stockholder in, the Yellow Aster company. This fact tends to support the statement regarding the inhospitality to outside capital.

When beginning this story, I suggested a discussion of the psychology of prosperity. Prosperity is contagious; it breeds optimism. Most of the inhabitants of Randsburg are either miners who are earning excellent wages in the California Rand Silver mine and at neighboring prospects or they are owners of old mines or leases in either the gold or silver 'zones' of the district. Those in the first class are prosperous; those in the second are optimistic. The rich silver ore that is being mined from an orebody two miles distant can have little significant geological relation to the gold-bearing veins, but it has

had the effect of renewing the confidence of these faithful old adherents to a 'camp' that has been almost dead, so far as gold mining is concerned, for several years. They point to the millions produced from shallow workings in the past; they point to the fact that, except for the Yellow Aster company, nearly every man did his own mining, spent his money as fast as he got it, and accordingly didn't have the capital to follow the lode when it faulted or when the grade of the ore diminished. They point rhetorically to Butte, to Virginia City, to Leadville, and they declare that Randsburg's only need is outside capital to develop 'at depth' the mines that are already opened. Then, they say, will follow a resurrection that will make the present prosperity seem like the

flurry before a storm! These old-timers are pleasant to talk with; their hope is the fond hope of every miner; and, as I say, their faith is bolstered by the prosperity of their neighbors who are mining silver. No one can help but wish that their dreams may be realized.

During 1916, 1917, and 1918 the Atolia mine, five miles to the south-east, was in active operation, and Randsburg enjoyed some of the fruits of a payroll that amounted to about \$60,000 per month. The Atolia during this brief period produced nearly \$10,000,000 worth of tungsten ore. However, in the spring of 1919, when the demand for tungsten ceased, the town was very quiet; the only activity was some desultory development work and prospecting for gold. Among those who persisted in digging were the owners of the K C N lode claim, over which passed the highway from Randsburg to Atolia and thence to Mojave. To many, K C N suggests the cyanide process of extracting gold; but the locators

of this claim were more intent upon mining ore than on treating it. K stood for Kelly, C for Coons, and N for Nossler, which introduces three of the principal characters in the present story. John W. Kelly had mined at Randsburg years before, after which he had gone to Bakersfield, where he had served as Sheriff of Kern county for several terms. Miss Edith F. Coons was County Assessor for Kern county, having succeeded J. M. Jameson, for whom she previously had been deputy; and Jack Nossler was a typical miner who boasted no particular accomplishment other than the ability to sink a hole into hard rock under adverse circumstances. He was the type of miner that the 'movie' directors try to imitate—I say "was" because outwardly, at least, he no longer 'is'. The fourth partner was W. H. Williams, familiarly and generally known as 'Hamp'. His mother was a Piute Indian and his father was a prospector of considerable intelligence. From them probably he has inherited his instinct for living in the hills and searching for mineral. He had studied enough to know something of the character and the habits of ore-bearing rock. Some years before, he had discovered the Cowboy and the Gold Peak mines in the Amelia district near Bakersfield, but in 1919, like Nossler, he was financially 'broke'.

Accordingly, these two did the work on the K C N claim while Kelly and Miss Coons supplied the money to buy powder, tools, and 'grub'. In the course of a conversation with me during my recent visit to Randsburg, Hamp said a number of interesting things; among them was this: "Miss Coons was a good gambler all right". This, I believe, is as genuine a compliment as was ever given one prospector by another—for Miss Coons is truly a prospector, even though she did not share in the actual work of searching for ore. For a long time she sent Nossler and Williams \$75 per month from her none too generous earnings, which she might have spent for more tangible things; that the 'investment' made her wealthy is to the credit of Dame Fortune, but to Miss Coons must be accorded the honor of having the nerve to play the game. Every one with whom I talked has a high opinion of Miss Coons.

The K C N shaft reached the depth of 100 ft. without revealing shipping ore, although some good stringers were cut. Williams and Nossler were feeling rather blue, when Kelly received a letter from Los Angeles inquiring about possible deposits of hematite suitable for making paint. He persuaded Hamp and Jack to go across the valley east of the K C N ground and stake some claims that he thought might contain hematite. This they did on the 12th day of April 1919. According to Hamp, Nossler started ahead of him on the return journey to the camp at the K C N. Williams, following, found Nossler sitting near a pile of loose rock on the side of the hill about half a mile from the K C N claim and only 30 ft. from a well-traveled road. The rock near where Nossler sat had apparently been blasted loose from the lode by some prospector; Jack was idly looking at a piece when Williams came up. "That's funny looking

stuff, Hamp; I wonder if it's any good?" inquired Nossler as he handed it over. Nossler's mineralogical examination had concluded with a fruitless search with his lens for free gold; Hamp was more sophisticated—he knew hornsilver when he saw it! He wisely declines to express an opinion as to the exact phraseology of his pronouncement; even seasoned prospectors do not stumble on a fortune in the middle of a desert and retain their composure, so it is reasonable to suspect that there was some picturesque language wasted in the vicinity of Randsburg along about sundown of April 12, 1919. The upshot was the taking of two samples, one from the part of the 15-ft. outcrop that looked best, and the other from the entire 15 ft. The assay-results from Los Angeles showed 280 and 360 oz. of silver per ton, though strangely

RANDBURG AND VICINITY

enough the richer sample was the one the men thought came from the entire 15 feet.

In addition to the silver, each sample contained about three ounces of gold per ton. Here I venture to address a few words of admonition, and more particularly of encouragement, to the prospector. Probably 100 men had noticed this outcrop and had examined the rock; many of them had even gone so far as to break up some of it for testing in their pan. But the gold is not free; it will not 'string' a pan, although a ton of the ore contains several ounces of it. The moral is that a prospector must educate himself in the elementary principles of mineralogy; otherwise his work cannot be efficient. The detection of gold that is combined to form other minerals may be difficult, but at least the prospector should familiarize himself with a few dozen common minerals such as hornsilver, as Hamp Williams had done. Looked at from a different angle, these same circumstances hold much encouragement for the prospector. For years this remarkable deposit lay undiscovered, although it was in the path of scores of men whose lives were spent in searching for likely-looking outcrops. The complaint is sometimes made that all the good lodes have been discovered, or that most of those remaining do not appear

on the surface and must be found by costly exploration with diamond-drills, churn-drills, or other expensive machinery. The California Rand mine belies this conclusion; the narrative of its discovery should put new heart in our friend the prospector. There are thousands of square miles of California, Nevada, Arizona, Utah, and other Western States that offer the most attractive possibilities of rewarding his efforts. It is safe to say that there are hundreds of orebodies just as good as that of the California Rand—rich as it is; all that is necessary is to find them. Prospector, take heart! Equip yourself properly with the paraphernalia for making tests, with a reasonable knowledge of minerals, and with the persevering spirit without which no prospector ever succeeded, and go out in the hills. If your courage flags,

there will be more hereafter, but all his transactions with the company seem to be marked by a spirit of square dealing. He sampled the outcrop carefully; the returns from his samples verified the former results, and the probability of opening a bonanza was established.

Investigation revealed the fact that the discovery was made on the Juanita claim (shown on the accompanying map), and that this claim was still valid by virtue of the performance of the annual assessment work. The other claims in the vicinity had lapsed. A man named McCormick, of Los Angeles, had located the claim and had sunk a shaft 130 ft. deep and driven a 75-ft. adit in a fruitless search for gold ore. The shots that had exposed the rock where Hamp and Jack found it were doubtless put in by McCormick's men when they were prospecting.

J. J. Nossor
W. Hamp Williams

J. M. Jameson
J. W. Kelly

THE FIRST LOT OF HIGH-GRADE ORE, A FEW OF THE OWNERS, AND SUNDRY VISITORS

think of Hamp Williams and Jack Nossor and the California Rand, or, for that matter, of a hundred others whom fortune favored before them—and since.

Kelly was a cautious individual; he wanted to be sure. Accordingly he wrote to Jameson at Bakersfield to come out and bring Edward T. Grady with him. During the later period of the development of the K C N, Miss Coons had been pressed for money, and Jameson had agreed to advance \$1000 for her. Accordingly it was agreed that Jameson should have half of the quarter interest held by Miss Coons by virtue of her grubstake agreement. Grady was a man of considerable experience in mining and they all had implicit confidence in him. I am told that if he had been so inclined, Grady, with his superior knowledge of business, could have obtained a large share of the mine for himself; that he did not, indicates that the confidence of the others was well founded. He is now making a fortune for himself and his partner from the Grady lease, concerning which

Like hundreds of others who had passed over the outcrop, they were seeking gold, not silver, and they accordingly overlooked the huge deposit of hornsilver. Kelly was delegated to go to Los Angeles, where he obtained from the son of McCormick, who had died in the meantime, a bond and option to buy for \$5000. In the meantime the Uranium group of claims was staked, thereby effectively covering what then appeared to be the valuable ground.

As I have related, Williams and Nossor were without money; had they known how far the rich ore would continue below the surface and how wide the vein would be, they would have needed none except what was required to buy their grub while they dug out a few carloads themselves. When work was started a huge block of ore 22 ft. by 18 ft. in horizontal section and 70 ft. deep was mined, beginning at the surface; and every pound from this pit was shipped to the smelter. Until dividends amounting to \$96,000 had been declared, the mine was

Looking Down the Valley Toward Atolia

The Company's No. 2 Shaft

Grady Lease Shaft

The Company's No. 1 Shaft

TWO VIEWS OF THE CALIFORNIA RAND SILVER MINE

literally without a dump. However, this could not be foreseen, and accordingly Williams and Nosser each sold half of his quarter interest for \$1000. Alfred Harrell, editor and proprietor of the 'Bakersfield Californian', took an eighth interest, and a group of eight men, including Grady, divided the other eighth equally. Harrell is now president of the company and the leading figure in the administration of affairs; he has been highly successful in directing the general policy of management.

An episode connected with the exercising of the bond and option is interesting for the reason that it involves a nice point of law. Mining claims in California are not community property between husband and wife; however, if both husband and wife contribute funds for the performance of assessment work, it seems that an unpatented claim becomes a community interest. Kelly had neglected to get the signature of Mrs. McCormick on the option, which was being held in escrow in a Los Angeles bank. The terms of the bond provided that McCormick should receive a small proportion of all smelter returns until the \$5000 had been paid. He accepted the checks sent him as his share of the proceeds from the first two shipments, but the third draft remained uncalled for in a Los Angeles bank. When two weeks had elapsed and the remittance was still unclaimed, Mr. Harrell at Bakersfield quite naturally became alarmed, particularly in view of the fact that McCormick was a lawyer and would no doubt be aware of his technical rights; obviously, it would not be difficult to establish the fact of Mrs. McCormick's participation in financing the performance of assessment work. Harrell endeavored to get into communication with McCormick by long-distance phone, but the latter apparently did not care to discuss the matter by phone and failed to respond to the call. Thereupon Harrell wired to Jameson, Kelly, and Miss Coons, at Randsburg, directing them to meet him at Mojave that night. In company with Dwight L. Clarke and C. V. Anderson, respectively secretary and attorney for the company, Harrell drove to Mojave and the whole party, comprising the owners of the majority of the shares in the company, made a night ride by automobile to Los Angeles, reaching their destination at daybreak.

The 'board of strategy' held a conference on arrival at Los Angeles. It was finally agreed that, if necessary, as much as \$50,000 would be paid to settle immediately with McCormick rather than involve the mine in litigation.

Kelly, who had done the original negotiating, volunteered to interview McCormick. His first move was to tender the unpaid portion of the \$5000 with the explanation that his associates, in order to facilitate other financial arrangements, desired to fulfill the terms of the option at once. He then simulated great astonishment when he was informed of the irregularity in the signing of the bond. During the ensuing discussion, intimation on the part of Kelly that his associates might consider the payment of \$10,000, to avoid any controversy, failed to arouse any outward enthusiasm in McCormick; Kelly

withdrew, ostensibly to communicate the surprising revelation to his associates.

The next move in the negotiations, which had some of the elements of an interesting poker game, was a second visit to McCormick's office, this time by Harrell, Jameson, Kelly, and Anderson, together. Harrell, who acted as spokesman, relates the story of the interview in these words. "After some preliminary sparring, I put the bald query: 'Well now, Mr. McCormick, how much do you want, spot cash, to sign a deed according to the option given to Kelly?' 'I ought to have \$15,000', was the reply. 'Bring the deed, signed by yourself and wife, downstairs to the bank', I said; and in fifteen minutes the transaction was complete. An hour later we started on another night ride back to Randsburg, but with a heavy burden lifted from our minds." Riding at night on the desert is exhilarating under any circumstances; added to this was the satisfaction of having cleared their title to the property that they confidently believed would become California's greatest silver mine, and of having 'saved', incidentally, \$35,000 in cash. The serenity of the travelers on the return journey to Randsburg doubtless contrasted sharply with their feelings of the previous night when they didn't know whether they owned a mine or not.

Sundry transactions in the stock, which incidentally has never been offered on the open market, are of interest. When the 'pit' was 20 ft. deep, Ben Sill, an oil-operator of Bakersfield, paid \$50,000 for an eighth interest, 1/64 of which came from Miss Coons and 3/64 from Kelly. This sale was negotiated by Grady, who also, a little later, sold an eighth interest to a syndicate of Bakersfield men, one-sixteenth coming from Nosser and the same from Williams. The consideration was \$105,000, or on a basis of \$840,000 for the entire mine, which at that time consisted of a pit-like shaft only 90 ft. deep. That the judgment of the purchasers, or perhaps I should say their luck, was not bad is indicated by the dividends that the company has paid already.

Next comes the story of the Grady lease. In the accompanying photograph there can be seen on the hill to the left a bold outcrop that stands out like a 'dike'. This silicious dike can be traced in a northerly direction along the hillside, where it outcrops about 125 ft. west of the discovery shaft. Surface indications all pointed to some definite relation between this dike and the ore deposit, and accordingly claims were staked with their side-lines approximately parallel with the strike of the outcrop. Numerous geologists and engineers who visited the district were frank in expressing the opinion that the orebodies should be adjacent to this dike, or that they should be found in near-by veins or fracture-zones parallel with it. In order to hasten prospecting of its ground the company encouraged lessees to develop small blocks. The accepted theory that the trend of the dike gave the key to the disposition of the orebodies guided these lessees in the selection of their ground, with the single exception of Grady, who chose for himself and his partner, Ben Sill, a block adjoining the Uranium No. 2 claim

on the south-west. This was in the area known as the 'flat', and the selection was ridiculed by everyone who pretended to be able to fathom the mysteries of local geology. However, Grady started sinking; and he continued to sink persistently through barren schist for 260 ft. At this point the shaft entered high-grade ore in a deposit that appeared to be of considerable size.

The terms of all the leases, including Grady's, were

ing *wholly* upon said premises, together with the dips, spurs, and angles of such lodes; but to be confined in the working of the same to the boundaries of the end-lines of said leased premises as same are established and shown on the plat attached hereto and made part hereof, and it is distinctly understood and agreed that the said lessee shall not be entitled to work any vein or lode which apexes wholly or *in part* off of said premises, where any

CLAIM-MAP OF THE RANDSBURG DISTRICT

peculiar in that they contained an 'apex' clause. Ordinarily a lease of this character defines certain limiting planes and provides that the lessee may mine whatever ore he is able to find within the included block of ground, irrespective of the strike, dip, or other structural features of the lode or lodes. It is customary to place a comparatively short time-limit upon the operations of the lessee, thereby preventing him from profiting too greatly in the event that he finds large orebodies. However, in the California Rand leases the following provision, quoted verbatim, is made: "together with the right to said lessee to mine said strip for all lodes apex-

such lode shall dip under or pass beyond said leased premises". The italics are mine.

Construed literally, this provision, I am inclined to believe, would leave the lessee little inducement to work at all; there would be small chance of any vein "apexing wholly within the said premises", which consisted of a block only a few hundred feet in lateral dimensions, and the lessee apparently would be deprived of the right to do any mining whatsoever. The intent, I am told, was to convey during the period of the lease, mining rights similar to those of an original claim-holder. If a segment of the apex of a lode on its strike lay within the

vertical planes of the leased block, that segment or portion of the lode lying between the planes through the end-lines could be mined on its dip. Extra-lateral rights were to be recognized. Apparently the lawyer who drew the indenture was familiar neither with physical conditions as they exist in the ground nor with the pitfalls of legal phraseology appertaining to 'apex' geology.

However, when it became evident that Grady had found ore, the company officials brought out a copy of the lease and raised the question of apex. No one could tell just where the lode that Grady had found really outcropped, or whether it outcropped at all. Its apex might be underground; it might be within the limits of Grady's lease; or it might not be. The geology of the district presents numerous interesting features, which I shall point out in a later article.

Grady's partner, Sill, was a large stockholder in the California Rand company, and he was anxious to avoid a quarrel. Grady, likewise, saw the disadvantages of a legal fight, and therefore proposed that the company purchase all the rights of the lessees for \$21,000. Sill agreed that, if the directors declined to compromise on this basis, he would support Grady, who was convinced that the lessee had a fair chance to prevail in the courts if a law-suit was to ensue.

The company had only the original inclined shaft and it would certainly need another unless the orebodies 'played out'; Grady had spent some \$15,000 for equipment and for sinking, and he had opened some rich ore, although neither the extent of the shoot nor the size and trend of the lode had been determined. These were obvious considerations that favored making the purchase, which moreover would prevent any possible dispute in the event that a large orebody was opened. Nevertheless, the officials of the company, largely influenced by the advice of Jameson, who had become general manager, declined to make the purchase for \$21,000. That the decision cost them a million dollars or more has been revealed by subsequent events; but whether the decision was a blunder in light of the conditions at the time, is a question that cannot be answered. If it was, Jameson had the consolation of knowing that many another million had been lost by errors of judgment with regard to mining property.

As soon as the offer was refused Grady started in earnest to open his ore. Within eight weeks he had done enough development work to show that at least a quarter of a million dollars was assured; the shoot in one place was 28 ft. thick and the ore averaged more than \$100 per ton, with silver calculated at \$1 per ounce. On its apparent strike the lode had been opened for 100 ft. and the drifts were still in ore. The lessees' shaft was but 300 ft. from the company's shaft, and the 600-ft. by 300-ft. block by with its long dimension along the side-line of Uranium No. 2 in the general direction of the strike of the ore. It appeared to be likely that a goodly proportion of the orebodies lay beneath the surface enclosed by Grady's lines. Both Grady and the officials of the company realized this; but both sides were keenly aware of the undesirabil-

ity of going to court to settle the question of ownership of the ore under the apex clause of the lease.

With a display of practical common sense that does credit to all concerned, and with a spirit of tolerance and willingness to compromise that is only too rare, they put their heads together to find the best way out of the difficulty. From various sources I gather that they were influenced to a large extent by this idea: "There is plenty of silver here to make us all rich if we go ahead and mine it and sell it as rapidly as possible; if we quarrel, the production of ore will be delayed, our organization will be demoralized, and the experts and lawyers will get most of the money. Let's settle the matter once and for all and then bend all our energy toward producing silver while the Pittman Act assures us a good market". If Messrs. Harrell, Grady, Sill, Jameson, and the rest had stopped to analyze their motives I believe they would have discovered some such train of thought, although I suspect that, if the facts since revealed regarding the lodes and orebodies, had been known at the time, the terms of the compromise would have been somewhat less favorable to Grady and Sill. At any rate, the outcome was a settlement by mutual agreement reached within a short time. Grady and Sill agreed to decrease the size of their block to 120 ft. square in lateral dimensions, thereby giving them 60 ft. instead of 300 ft. in each direction along the strike of the lode, and diminishing by more than half the distance in the direction of the dip. A horizontal plane passing through the 450-ft. level of the Grady shaft was also agreed upon as the lower limit of the block. On the other hand Grady was given an extension of six months, or until January 27, 1922, during which to extract his ore. By the terms of the settlement all questions of apex were dropped, the lessees being governed only by the boundaries of the ground. Even though the lessees may have gotten the best of the deal the settlement illustrates the virtues of negotiation and compromise in averting 'war'. Of course, it required cool heads and a lot of common sense.

I may add that plain common sense has been the biggest asset of the men who have been in charge of the California Rand mine. Until recently there has been no one connected with the management of the property in an executive capacity who pretended to be a mining engineer. Jack Nosser was in charge of actual mining at the start and John W. Kelly looked after business affairs for a short time. However, the man who early assumed the management and who guided the destinies of the company until his death in June 1921, was J. M. Jameson. Jameson knew little or nothing about running a mine when he undertook the job, but apparently he had some sound ideas of business and these he applied to the operation of the mine. One engineer who had examined the mine remarked to me that he was astonished that so few mistakes were made, and that the shipments of ore had been maintained with such regularity. Although the orebodies are undoubtedly large and rich, the veins split and pinch, and it is no easy matter to maintain regular shipments of high-grade ore.

A notable feature is the modest character of the surface equipment and buildings; some managers would have spent an additional \$100,000 on unnecessarily elaborate buildings. It is false economy to get along with inefficient equipment when better can be afforded; but a handsome office-building or a steel structure to house the hoist are 'trimmings' that can wait for an advantageous time, without interfering with the production of ore. Frequently, an important function of elaborate surface plants is to afford material for impressive illustrations in prospectuses and otherwise to assist in promoting the sale of treasury stock to the esteemed public; this has never been necessary at the California Rand property. A small group of the stockholders felt that Jameson's policies were not sufficiently progressive. However, during the period of his management, No. 2 vertical shaft was started and sunk 150 ft., and tests were made by seven different metallurgical engineering firms with a view to determining the most desirable treatment for the low-grade ore.

Jameson died in June 1921. He was succeeded as general manager by C. S. Meroney who, first as accountant and later as superintendent, had been his right-hand man. I believe that Mr. Meroney is endowed, among other virtues, with a 'nose for ore'; to him more than anyone else is due the credit for directing the development work and the stoping in such manner that it was possible to maintain shipments regularly.

In June of this year, M. N. Colman was engaged as mill superintendent. He has correlated the results of the metallurgical tests made by the various firms and has designed a 100-ton flotation plant, which is now being erected. The tests of the ore and the design of the plant are interesting; they will be described in the third article of this series. J. M. Fox has recently assumed the position of mine-superintendent; with these two competent and experienced engineers to direct the technical work, under Mr. Meroney, efficient and economical operation seems assured. A valued member of the operating staff is T. D. Walsh, who became mine engineer a few months ago in succession to V. A. Gillis, whose connection with the company was brief. Mention should be made of the valuable advisory work of Morris B. Parker who, in the capacity of consulting geologist during part of 1920 and 1921, assisted in the solution of some of the geological problems and made several estimates of the ore reserves.

The main shaft is inclined at an angle of 15° from vertical; it was 730 ft. deep on August 15. Levels have been established at intervals of from 40 to 70 ft.; eleven of them having been opened to date. The total amount of development work is approximately 12,000 ft., exclusive of that done in the Grady lease. Ore has been mined from all the levels except the eleventh, on which the cross-cut has only recently cut the vein. The new vertical shaft is 350 ft. from the original shaft in the direction of its inclination. Sinking has reached the 230-ft. point, the plan being to continue, without interruption, to the 1000-ft. level. The site of the mill was selected so as to permit the economical handling of the ore directly from

the skip-bins to the crushers. The estimate of the reserves of mill-ore is necessarily indefinite for the reason that little of it has been actually exposed, but a conservative figure is 100,000 tons of ore averaging \$20 per ton, with silver selling at \$1 per ounce. Manifestly it has been good policy to concentrate effort on the mining of high-grade shipping ore rather than to develop milling ore.

Grady and Sill, from their lease, have been shipping approximately 60 tons of high-grade ore per day for several months. The resulting royalties net the company from \$10,000 to \$15,000 per month. The lease has until January 27 to run and Grady estimates that he and his associates will make a clear profit of more than a million dollars as a result of their operations.

Adjoining Franium No. 5 is the Coyote claim owned by the Randsburg Silver Mining Co., in which John W. Kelly and Ernest Blanck are the dominating figures. Both of them are interested financially in the California Rand Silver, and Blanck is a director of the company. A shaft has been sunk on the Coyote claim approximately in line with the original California Rand inclined shaft and the Grady lease shaft. Recently a vein of shipping ore has been opened on the 500-ft. level from this shaft. This discovery has stimulated others who have been working in the vicinity. Bisbee and Bray, lessees who have sunk a 400-ft. shaft on the Oscliek group of claims, which lies south from the Coyote, are employing 20 miners and are hastening work in the expectation of finding ore; and Elkins & Flynn are actively prospecting, by means of a diamond-drill, the Silver Reef claim, adjoining the Coyote on the east. In addition, there are a number of smaller operations being carried on principally by lessees, who hope to 'strike' high-grade near the surface.

Including those employed in the gold mines in the western portion of the district, there are probably 200 men in Randsburg at work, earning from \$6 to \$8 per day; miners are paid \$6 to \$6.50, depending upon the nature of their work. This is, I believe, the highest wage-scale prevailing in the United States. The California Rand company has made no reduction in wages since the peak was reached during the War. The policy of the company has been to share prosperity with its employees.

There is one manifest result of high wages; general prosperity! The sight of Randsburg is a tonic for the depressed. It is unfortunate that there is no way to give it general distribution—in bottles, perhaps; it might hasten the return to normality. With the exception of the men who live in quarters supplied by the company at the mine, I failed, during a two-day stay at the mine, to see anyone coming to work on foot. I venture to say that there are more automobiles per capita in Randsburg than in any other community in the United States; and that ratio is a pretty good index to prosperity. Everybody in the small world that centres at Randsburg is hard at work; everybody has money; everybody is optimistic. How different things would be if Hamp Williams had not known hornsilver when he saw it!

(To be Continued)

Mining in Russia

Negotiations of the Russo-Asiatic Corporation with the Soviet Government

We give herewith a letter addressed by Mr. Leslie Urquhart, chairman, of the Russo-Asiatic Corporation, to the shareholders of that British company; to his letter we add the one that he sent to Mr. Leonid B. Krassin, the trade representative of the Soviet government in London, explaining why the company found it impossible to accept the conditions under which a resumption of work at the company's properties in Siberia was to be permitted by the authorities at Moscow.

London, October 12, 1921.

To the Shareholders

I am requested by my colleagues on the Board of Directors to send you herewith copy of a letter to Mr. Krassin in regard to the negotiations with the Soviet authorities.

The negotiations, which had been inaugurated some five months ago, have been lengthy, mainly because of the large principles involved, but before leaving for Moscow I was able to inform the shareholders that the Moscow government had telegraphically agreed to the basis of the proposed agreement discussed with Mr. Krassin—the return of our properties and working capital in the form of a concession. There were, however, certain outstanding questions on which we were not in complete accord but which we had reason to believe would be settled to our satisfaction.

As a result of these negotiations I was invited by the Soviet government to Moscow for the purpose of agreeing the final terms of the proposed contract for the return of our properties. I therefore left for Russia on August 14, arriving in Moscow on the 20th of that month, and from that date up to the evening of my departure on September 12 I was continuously engaged with the Technical Economic Commission appointed by the Soviet government for the above purpose.

The Commission was a large one including men with business experience in important affairs, some as proprietors or technical managers of large enterprises, engineers, or lawyers in the old days. The direction and decision, however, as to the different clauses of the contract belonged to three High Commissioners—ministers of the Soviet government—who in turn had to submit the draft contract to the final decision of the Council of People's Commissaries under the presidency of M. Lenin. Representatives of different departments of the Government attended the meetings of the commission when called in order to advise on special points or defend the interests of the departments concerned.

As a result of these negotiations a draft concession agreement embodying 27 clauses was prepared and discussed. The intention of this agreement was to return to us our properties in the state they were at the time of nationalization, together with the stocks of materials, working capital, etc. Eighteen of these clauses were agreed by me with the Concessions Committee in Moscow, and in other clauses but slight disagreement existed. It will be seen, however, from the enclosed letter to Mr. Krassin that there are vital questions at issue which made the conclusion of such a contract with the Soviet authorities inadvisable and, indeed, impossible.

Under such circumstances the conclusion of any contract with the Soviet government would be futile and, as stated in our letter to Mr. Krassin, we prefer to remain as heretofore claimants against Russia for damage caused by the Soviet

government for unlawful appropriation of our properties and working capital.

While in Moscow I had the opportunity of seeing a number of our employees and engineers who had recently come from the properties, and who had first-hand information not only as to the physical condition of the mines and works but also as to the attitude of our workmen and employees.

This information is reassuring as to the general good feeling among the people and of the condition of our properties at Kyshtim, Ridder, Ekibastus, and Tanalyk.

While the directors keenly regret that, notwithstanding all their efforts and their strong desire to resume operations in Russia, an agreement at the present time is impossible, they are satisfied they are acting in the best interests of the shareholders and that the position of the company will be strengthened by the decision and attitude thus adopted.

Yours faithfully,

Leslie Urquhart, Chairman.

London, October 11, 1921.

Leonid B. Krassin, Esq.,

Russian Trade Delegation,

Dear Mr. Krassin,

At our meeting yesterday I had the honor of informing you personally that on my return from Russia I submitted the draft concession contract to my colleagues on the Board of the Russo-Asiatic Consolidated to whom, as well as to some of the principal shareholders, I tendered my views on the conditions in the draft contract and on the position in Russia generally.

I was naturally unable to report fully to the shareholders of the company until I had the advantage of discussing with you the position in detail, and I have now repeated our conversation to my colleagues and it is my duty to inform you that I am authorized by my Board on behalf of my company to the effect that the measure of disagreement between us and the Soviet government on vital points of the draft contract is so great, the attitude of the Soviet government and the present political and economic conditions in Russia so impossible, that we cannot see our way at present to continue negotiations for the return of our properties, and prefer to remain as heretofore claimants against Russia for damages caused by the Soviet government for unlawful appropriation of our properties and working capital.

Your unfailing courtesy to me personally both before and during my visit to Moscow convinces me that I should be failing in courtesy to yourself if I did not give you in detail our reasons for coming to the above conclusion.

I need hardly remind you of the sincere desire which we have always evinced to resume work if possible in Russia and you will no doubt agree that we have shown our complete willingness to go a very long way in meeting the communist views of the Soviet government and that we did actually yield on many points, hoping by so doing we might be privileged to assist in re-establishing the economic life of that country and of giving bread to the starving and miserable workpeople at least on our own properties.

In the speech delivered on behalf of the Board at the general meeting of shareholders of the company held on July 6 last, I referred to the negotiations with yourself as representative of the Russian Soviet government in this country, which were inaugurated after discussion with and on the advice of the Board of Trade.

In reviewing the position in the speech we were under no illusion as to the facts of the Russian situation. We pointed out that Russia under her present communist system of state economy produces nothing to trade with, that the process of unlimited emissions of bank-notes has utterly exhausted the remnants of credit and that the stocks of products and materials of the old capitalistic system had been used up. The abolition of rights to property, of economic freedom and the complicated system of economic restrictions generally have killed individual initiative and enterprise while the elimination of private gain had destroyed all incentive to work and produce. The policy of nationalization of all industry and trade had killed foreign credits, and foreign capital without which the resuscitation of Russian industry will be difficult, if not practically impossible, would not be forthcoming if the present economic system were to continue.

On the other hand we believed it was the pressure of these inexorable facts, the stagnation, exhaustion, and suffering to which the communist system had brought the country that had forced the Russian situation from the beginning of this year to enter a new phase. In the Decree of March 30 last, which gave permission to peasant and town workers to barter and to trade, in the corn-tax replacing the forcible requisition of surplus grain from the peasant, in the denationalization of small industries, in the offering of concessions to foreign capitalists on terms which admitted the principle of private gain, we saw the beginnings of the re-establishment of favorable conditions for the resumption of industrial life in Russia.

Finally, we had in the negotiations with yourself further proof of an evolution to the right in the strivings of the moderate elements in the Soviet government to adopt an economic system and create an atmosphere in which foreign and Russian capital could operate and restore Russia to her former strength.

We made it perfectly clear in starting negotiations that we did not look on Russia exhausted and suffering as a hunting ground for this or that commercial advantage; we were not self-seekers or exploiters of other people's distress. All we asked for was the return of our properties in the condition they were in when nationalized, together with our working capital. We emphasized that we were not concerned as foreigners with the politics of Russia and that our only desire was to see the return of prosperity to that great country and to us as shareholders in this company and finally that if the negotiations did not lead to the complete and satisfactory re-establishment of our business in Russia it would be through no fault of our own, but through the fault of the Soviet government.

There are in all 27 clauses in the draft concession agreement. I will refer first to the 9 clauses in the draft contract regarding which it was impossible to come to an agreement and will deal later with the proposed contract with the Professional Workmen's Union, which the Soviet government stipulated must be supplemental to and part of the concession agreement.

Clause 2.

With reference to the return of all the properties of the Russo-Asiatic Consolidated to the company under form of a concession, the Soviet government proposed to exclude those lands which have been assigned or have to be assigned to the local population in accordance with the land settlement scheme of the Soviet government. This clause could not be agreed until the land to be demarcated and the new regulations under which the land, mineral and timber rights to be assigned were clearly defined.

Clause 4.

With reference to the return of our losses and working capital no definite agreement was come to.

Clause 5.

Referring to State control and new timber-felling regulations at Kyshtim and other properties of the concession; this could not be agreed until State control with reference to the new forest and timber regulations to be substituted for the old forest regulations, and the words "actual laws and regulations," be clearly defined.

Clause 7.

Could not be agreed until the instructions to accompany the decree referring to minerals to take the place of the old mining code were clearly defined.

Clause 15.

With reference to royalties payable on sales in lieu of taxation, the amount of royalty could not be agreed. It is obvious, as has been documentarily demonstrated, that the company could not pay the royalty demanded without loss. The company refused to consider an Excess Profits Tax.

Clause 19.

My draft of this clause stipulated that all workers employed by the company, whether Russian or foreign subjects, should be regarded as engaged on work of State importance and should not be liable to labor conscription or to any kind of forced labor generally; their property to be free from any special local taxes or charges, requisitions and confiscations; their homes free from regulations limiting living space, emigration and other similar measures of force. That all searches, arrests and extraction of papers or documents should only be carried out against employees and workmen on the concession by decision and in the presence of the judicial organs. Further, that qualified workmen and employees were to be free from military service and mobilization and on an equality with persons employed in the most important State enterprises.

The Commission refused to agree to my draft and substituted another limiting the above privileges, and even then only with reference to foreign subjects—Russian citizens working on the concession were to be subject to all these restrictions and limitations of their liberty.

Although I protested strongly against this unfair discrimination in favor of foreign as against Russian working men on common grounds of humanity, equality and justice, the Commission insisted on their wording of this clause.

Apart from the economic absurdity of agreeing to conditions whereby any one of the local organizations of the Soviet government could take a highly paid Russian employee, brain worker or skilled workman, away from his productive work on the concession and force him to clean the streets or do any other unskilled labor, and even although this is the practice at present, speaking for myself, for my colleagues and I am sure for every one of the shareholders of this company, we could not become parties to a contract containing a clause so humiliating and so unjust to our fellow-workers.

Clause 24.

Referring to period of concession. The Commission offered a 72 years' lease. The company insisted on a period of 99 years for the concession, in view of the fact that the Kyshtim property is freehold and that the other properties were held either until exhaustion or under long leases which could, no doubt, have been renewed if required.

Clause 25.

Referring to right of purchase of properties by the Government after term of years: I considered this clause should have been deleted, but in any case the conditions proposed by the Soviet government are unacceptable. If such a clause is to be retained the company insists on my wording.

Clause 27.

Arbitration. All disputes and misunderstandings as to

the meaning of or fulfilment of the Concessions Agreement and of additions or subsidiary agreements thereto to be referred to a permanent Arbitration Commission consisting of three members, one member to represent each side, the third or president to be elected by mutual agreement. Failing such agreement the Commission proposed that the president, who must be a Russian, would be nominated by the Russian Academy of Science. The company insisted that, failing agreement, the president, who must be a neutral, neither a Russian nor a British subject, be nominated by a foreign society, preferably the American Institute of Mining and Metallurgical Engineers.

As communism does not recognize the right to private property on which the previous civil and criminal code was based, magistrates have been suppressed and courts of justice have been abolished. Nothing has been substituted for these except a so-called Court of Revolutionary Conscience. Under the new system, taxes have been abolished, the mining, factory, customs, forest and railway laws and regulations, in fact all previously existing authorities have been destroyed, as is evidenced by the clauses of the draft concessions contract reviewed in this letter, and nothing but incomplete decrees and instructions which are issued daily have taken their place. Further, the communistic system does not recognize any obligations between individuals and therefore no contract or obligation between two persons can be enforced; nor does the State itself recognize any obligation to individuals or subjects. The only obligation recognized and enforced is the absolute subjection of every individual to the State.

This extraordinary position, the absence of all laws and regulations, dominated as you are aware the discussions all through the negotiations. The suggestion made by the Commission that questions in dispute or of civil law should be referred to the Courts of Revolutionary Conscience was impossible of acceptance, firstly because the members are not of too high intelligence, have received no legal training and all belong, without exception, to the communist party. As the communist creed does not recognize private property or that capital has any rights, judgment would naturally always be adverse to capital. This view was accepted by the Concessions Commission, and in order to meet the requirements of justice with reference to any issues which might arise in the working of the concession contract it was agreed that a court of arbitration was the only solution.

I can quite well understand the contention put forward at the meeting of September 12 that the Soviet government considers it undignified that questions of dispute between the government of Russia and a Concessionaire on Russian territory should be adjudicated by a foreigner appointed by a foreign scientific society. On the other hand the condition that the president or arbiter of the Arbitration Commission be a foreign expert nominated by a foreign scientific body was of vital importance to the company. It is the only safeguard (and at that only a moral safeguard so long as present conditions of lawlessness exist in Russia) that the terms of the contract would be interpreted in all fairness and justice for both sides by an unprejudiced umpire.

The acceptance of the proposal of the Soviet government would entail the danger that a communist might be appointed president of the Arbitration Commission, who for obvious reason would not be expected to render justice to capital; but even if he did not belong to the privileged communist party no man is a free man in Russia today; he is subject to labor conscription and forced labor, to every kind of restriction in his home or on his liberty of thought or movement, he is always in a position of absolute subjection to the communist state and, indeed, he and his family are dependent for their daily ration of food on the Government. How then can he be considered a free agent in adjudicating

in a dispute between the Soviet government and the concessionaire?

All-Russian Council of Professional Unions.

I now come to the proposed supplemental agreement with the All-Russian Council of Professional Unions, which is to form part of the concessions contract, this council being a department and organ of the Soviet government. This document is too long to review in full; I will, therefore, refer to only a few of the principal clauses.

To call this union a professional union seems to me a misnomer, for whether he desires it or not it is obligatory for every man or woman worker in Russia be he a brain worker, a doctor, lawyer, mining, civil or mechanical engineer, a skilled craftsman or unskilled laborer, to be a member of this union.

Clause 2 covers in the collective contract 39 different categories of skilled workmen alone whose rates of pay are based on wages paid in England and Germany, but it is beyond the skill of mortal man today to fix the rate of exchange; and further the conditions are not the same, as you know; the skill and capacity of the Russian workman is not nearly as high, the undertaking has got to house him and also supply him with food and all the necessities of life, which naturally entails a great increase in the working capital of the undertaking. I proposed that the rates of pay should be those paid in 1913 on the gold basis for the rouble, and although this was equivalent to a minimum of eight times what is being paid in State enterprises at present and would have been hailed with joy by the workmen, the proposal was refused by the All-Russian Council of Professional Unions.

Clause 9. The concessionaire is obliged to inform the professional unions of every engagement and every discharge of workmen. The transfer of persons employed in State enterprises to the enterprises of the concessionaire is only permitted on the same conditions as the transfer from one State enterprise or department to another. This means that without the permission of the heads of the department or State enterprise concerned as well as of the All-Russian Central Professional Union, a workman or employee may not, even if he desires to do so, enter the employment of the concessionaire. As all enterprises are State enterprises today the restriction on the personal liberty of the workman and the freedom of the concessionaire in operating and developing his enterprise is self evident.

Clause 13 insists that the concessionaire is obliged to purchase from abroad for a period of not less than seven years for the personal needs of the workmen and their families all food, provisions, clothes, boots, etc., and sell these goods at cost price. I pointed out that it was illogical that a period of seven years should be fixed in advance and that it was unreasonable to force the concessionaire for a period of seven years to bring, for instance, flour and provisions from America, a distance of not less than 10,000 miles from the Ridder property, when there is today wheat alongside in the Akmolinsk province which cannot be moved by the Soviet government. I suggested that if the professional union desired to safeguard the interests of the workmen we should be obliged to buy in the cheapest market and sell at the cheapest price instead of being asked to do the opposite. This suggestion was categorically refused and the professional unions insisted on their conditions.

All kinds of controls and provisions are made whereby the liberty of action and decision of the concessionaire are restricted by the professional unions; as a result there is no finality to an agreement with a workman even after the terms of his contract with the enterprise have been absolutely fulfilled.

The All-Russian Council of Professional Unions, supported by the Che-ka or Extraordinary Commission (both controlled by the communist party) is simply a political in-

strument for forcing on the Russian workers the extreme principles of international communism through the mechanism of the Government.

As you are aware some of the provisions of the draft contract are not in the economic interests of the workmen and have the effect of not only restraining the liberty and enterprise of the employer, but the personal liberty of the worker. Instead of permitting the worker and employer to come together to settle any differences amicably as in the past, the contract with the All-Russian Council of Professional Unions is intended to keep the employer and the workers apart, and by placing the interests of the workers in the hands of extremist members of the communist party or opportunists who are at the head of this organization, perpetuate the present strangle-hold not only on industry and enterprise but on the whole working and proletarian population of Russia.

I need not elaborate on this supplemental contract further as although we had lengthy discussions with its representatives no agreement was possible with the representatives of the professional unions.

It is with great diffidence, in view of its political aspect, that I am obliged to deal with the influences which the Che-ka or Extraordinary Commission for combating counter-revolutions would have on the fulfillment and operation of the concessions contract.

I quite realize that in times of revolution and more especially when an infinitesimal minority govern the destiny of a country, that plenary and arbitrary powers must be given to a police organization for combating counter-revolutionary activities. For this reason and although it may be that the leaders of the communist party or of the government were idealists and at first averse to violence, they found themselves obliged to resort to violent methods to keep themselves in power, and in order to establish their communistic system on an unwilling people. It was natural, therefore, that in destroying the former order, the process of nationalization and confiscation of all property brought about a period of anarchy, plunder, and loot. The Che-ka was the principal instrument in enforcing these measures, it rallied round itself not only communists, but criminals, both Russian and internationalists. The Che-ka is accuser, judge, jury and executioner with absolute power of life and death, and in addition to these plenary powers granted to it, this secret police has developed the most complete spy system of informers and agents provocateurs throughout every town and village of the Russian dominions.

For these reasons the power of the Che-ka has today eclipsed that of the Soviet government. History has shown that an organized and armed minority can by terror control an unorganized majority. By methods of calumny, corruption, and murder, the Che-ka controlled by the extremists of the communist party and their conscienceless tools, has established such a reign of terror that it keeps not only the Russian people in abject subjugation but even the leaders of the communist party, who are obliged to submit to their interference in the political and economic life of the State.

Every phase of the individual activity of the employer, his staff and his workmen in the operation of the proposed contract, even in the privacy of their homes, would be under the shadow and menace of this terrorist organization.

It logically follows, therefore, that with the abolition of the code of civil laws and all the legal authorities and regulations that govern the political and economic life of a nation there can be no justice. As long as the communist party controls the Soviet government, the Third Internationale, the Che-ka and the professional unions, any one of these instruments of the communist party may render inoperative any agreement which may be come to with the Soviet government.

May I also say that so long as the Third Internationale,

not content with the devastation of Russia by its communist system, is permitted by the Soviet government or communist party to continue its subversive efforts against the institutions of capitalistic countries, I do not see how it could be possible to obtain the finance and credits so necessary for the life and development of industry in Russia.

Allow me to say in conclusion that I had, as you know, very full and reassuring information as to the condition of our properties, which went to show that given a fair opportunity the time necessary to rehabilitate our business would by no means be so great as might be expected.

Our workmen and employees at all of the properties were pathetically anxious and hopefully waiting for us to resume work. I had many personal messages of goodwill and assurance on this point, and it is a matter of the keenest regret to me and my colleagues and shareholders that notwithstanding our sincere and anxious desire to re-start work and provide again for the well-being of our workpeople and their families, we are prevented from doing so for the reasons above given.

As the interest in these matters extends beyond the parties immediately concerned in these negotiations, I reserve the right to such publication as we may deem advisable.

Believe me, yours faithfully,

Leslie Urquhart, Chairman.

THERE is no standard classification of asbestos in general use, states an Arizona Bureau of Mines bulletin, but the Department of Mines of the Province of Quebec recognizes the following five grades. Crude No. I, Crude No. II, Mill Stock No. I, Mill Stock No. II, and Mill Stock No. III. Some mines ship only No. I Crude, others both No. I and II Crude, while still others send the whole product mined to mills which may produce from two to five different qualities of mill fibre. In order that prospectors may have some conception of the probable classification of good asbestos the following table has been prepared:

Quebec Department of Mines classification		Approximate length of fibre
Crude No. I.....	Over $\frac{1}{8}$ in.	
Crude No. II.....	$\frac{1}{16}$ to $\frac{1}{8}$ in.	
Mill Stock No. I.....	$\frac{3}{16}$ in. and over	
Mill Stock No. II.....	$\frac{1}{16}$ to $\frac{3}{16}$ in.	
Mill Stock No. III.....	Up to $\frac{1}{16}$ in.	
Asbestic	Very short fibres mixed with powdered serpentine	

Although the length of the fibre is an important factor in determining the grade and market price of asbestos, the value is also dependent upon the fineness of the fibres, the temperature at which they fuse, their flexibility, and their tensile strength. The value of chrysotile does not decrease in direct proportion as the length of fibre decreases. For instance, if fibre $\frac{1}{2}$ in. long, which might be worth \$1400 to \$2000 per ton, were broken in half, the resulting material might be worth only \$110 to \$150 per ton. The fibrous structure, toughness, incombustibility, and low heat conductivity are the properties that make asbestos valuable. The most important way in which asbestos is utilized is as yarn or thread, used in the manufacture of steam packing, fireproof cloth, rope, and brake-linings. No known substitute is available for the manufacture of the better qualities of these articles.

Book Reviews

First Aid and Rescue Work in Mining. By L. G. Irvine. 348 + xv pp., ill. South African Red Cross Society, Johannesburg. For sale by the 'Mining and Scientific Press', sole distributors in the United States, Canada, and Mexico. Price, \$2.

Dr. J. S. Haldane, who writes a prefatory note for this excellent little volume, remarks that, outside South Africa, Dr. Irvine's name is probably best known as a result of his papers on miners' phthisis and on the effects and treatment of poisoning by nitrous fumes. During the War there were numerous cases of poisoning in naval actions by nitrous fumes from burning explosives; the lung irritant gases employed so extensively in land warfare were similar in their effects. Many soldiers and sailors owe their lives to methods of treatment that were first introduced in this connection by Dr. Irvine and his collaborator, the late Dr. Macaulay. To those familiar with underground conditions and the special dangers of mining, it will be evident that the author has studied carefully all the recent advances of knowledge and their practical application. The chapters dealing with the safe transport to surface of injured men, with accidents from all varieties of poisonous and suffocative gases, with explosions and fires, and with rescue apparatus for use in suffocative air, embody all the results of recent investigations and practical experience. In the first part of the book the author has endeavored to meet the needs of all classes by placing in smaller type, or where they occur in the general text by enclosing in brackets, such portions or terms that a trained ambulance man ought to know but that an elementary student need not learn. Part I may therefore be used as a text-book for general courses in first aid. The description of methods include none but those that an extended personal experience of first-aid work in mines has shown to be reliable. Part II deals with special requirements. A large portion discusses accidents due to poisonous gases and the use of rescue apparatus. The contents of the book are arranged as follows: I. General structure and working of the body. II. Bandaging; the triangular and the roller bandage. III. Circulation of the blood; treatment of wounds and hemorrhage. IV. Fractures, dislocations, and sprains. V. Respiration, artificial respiration, and asphyxia. VI. Insensibility and unconsciousness. VII. Burns and scalds; injuries due to electricity; injuries to the eye, ear, and nose; snake bite. VIII. Poisons. IX. Transport of the injured; general management of first-aid cases. Appendix A deals with the contents of the standard first-aid box and Appendix B describes the Thomas extension splint for the thigh. The book should be in the hands of all who are responsible for the lives of others.

Steam Boilers. Edited by T. Croft, assisted by I. O. Royse, I. V. Le Bow, A. J. Dixon, and E. R. Powell. 412 pp., 5½ by 8, ill. McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$4.

This book was written as a practical treatise to help those who intend to enter for engineer's license examinations; it has been prepared primarily for men of little schooling who desire to acquaint themselves regarding the subject. A working knowledge of arithmetic will qualify anyone to read it intelligently; but it may be used effectively by others, regardless of training or experience, who seek information on steam-boilers. The principles presented throughout the text are explained by means of descriptive expositions or with arithmetical examples. At the end of each of the 25 divisions there are questions to be answered by the reader, and, where justified, problems to be solved. Detailed solutions of all the problems are printed in an appendix at the

end of the book. The functions, the history, and the modern types of boilers are first considered. The boiler codes and laws are discussed. The elements of modern boiler construction are presented under: boiler stresses and strengths, riveted joints, braces and stays, fire-tubes and water-tubes, manholes and handholes. This is followed by matters relating to boiler accessories, steam-generating and super-heating, boiler capacities, and ratings. The subject of boiler-room economy is dealt with under: fuels; draft and its production and measurement; combustion and firing; boiler settings and furnaces; mechanical stokers; petroleum and gaseous fuels; chimneys, breechings, and dampers; artificial draft equipment; fuel economizers; feed water and feed-water treatment; steam-boiler management, inspection and maintenance. The book will be found of value to the average engineer who is concerned with the work of boilers but who does not specialize in the subject. It has been excellently illustrated with special drawings. The only adverse feature that should be corrected in a future edition is seen in unnecessary capitalization in the bold-face type introducing the paragraphs.

Silver Bromide Grain of Photographic Emulsions. By A. P. H. Trivelli and S. E. Sheppard. 143 pp., ill. Van Nostrand Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$2.50.

The research laboratory of the Eastman Kodak Co. was founded in 1913. The results obtained are published in various scientific and technical journals; but the work on the nature of photography is so varied that it has been thought wise to prepare a series of monographs, of which this is the first to be published. It is hoped to cover the whole field of scientific photography. In the present treatise it is shown that the fundamental units of the sensitive materials used in photography are the small grains of silver halide that, imbedded in the gelatine, form the emulsion. These grains are of small size; they are precipitated in a colloid medium and have been considered as colloid aggregates. The result of study involving photo-micrographic work of a high order is to show that the grains of high-speed emulsions are crystalline and all belong to the same crystalline class. The catalysis of crystallization by nuclei is suggested as an explanation of some of the effects produced by the admixture of silver iodide with silver bromide in an emulsion, and the fact that traces of colloidal silver make the grains color sensitive is believed to be related to this. The contents of the book are as follows: I. The influence of ammonia on photographic emulsions and a theory of ripening. II. Von Weimarn's theory and the determination of the dispersity of silver bromide precipitates. III. Accessory factors influencing the dispersion of silver bromide emulsions. IV. Crystallization catalysis. V. Capillarity and crystalline growth. VI. Experimental study of the crystallization of silver bromide. VII. Classification of silver halide crystals. VIII. Silver bromide crystals of photographic emulsions. IX. Directions of most rapid growth in silver bromide crystals, and the occurrence of anomalous forms. X. The behavior of silver bromide and silver iodobromide crystals in polarized light. The book concludes with a summary of crystallographic study of silver halide grains, a bibliography, and indexes to authors and subjects.

Petroleum. By H. M. Petroleum Department with the co-operation of H. B. Cronshaw. John Murray, Albermarle street, London, W. Price 5s.

This is one of the series of monographs that is being prepared under the direction of the Mineral Resources Committee of the Imperial Institute. It contains facts, and statistics in tabulated form, relating to the world's resources of petroleum as determinable from present information. An extensive bibliography is appended.

REVIEW OF MINING

THE HECLA-STAR CONTROVERSY

Extensive propaganda is being used by Eugene R. Day and associates in order to prevent the purchase of the Star mine, in Idaho, by the Hecla company. The American Smelting & Refining Co. is behind the Day interests, who control the Northport smelter, in Washington. The abandonment of this plant would mean the elimination of the only independent smelting concern in the vicinity; and future competition in the lead-smelting industry would be confined to the Bunker Hill & Sullivan and the American Smelting & Refining companies. The case to be tried shortly in Spokane is a secondary issue, but it is one that is complicated by the fact that the Bunker Hill company, before entering into negotiations with the Hecla company, had taken a purchase option on the Star mine. The Federal Mining & Refining Co., a Guggenheim subsidiary, entered Star ground and removed, according to the estimate of the Star company, ore valued at several million dollars.

COPPER SALES DURING OCTOBER

Sales of copper during October amounted to 140,000,000 lb., the largest for any month this year. The increase is accounted for mainly by advance-buying on the part of domestic consumers who had become frightened lest producers would boost the price considerably during the next few months. Included in October sales are large tonnages for December and first-quarter, 1922, delivery. During October one large consumer covered his requirements for all next year. It is this advance buying rather than any sudden increase in domestic or foreign consumption that accounts for the unusual size of the sales despite business being exceptionally quiet for more than a week during the last half of the month as a result of the threat of labor troubles upon the railroads. Monthly shipments to consumers have averaged about 80,000,000 lb. per month recently. Despite aloofness of British buyers during the month, foreign sales were good. Japan was a large buyer, induced by the prospect of rising prices, while Germans rushed to fix their fast-depreciating marks into copper of surer and more certain value. Sales to France were encouraging throughout the earlier part of the month.

RESUMPTION OF OPERATION OF INTERNATIONAL SMELTER AT MIAMI

The International Smelting Co. will re-start part of its plant at once. This, however, does not mean that the Inspiration Consolidated Copper Co. will resume mining, as was reported in some quarters. Officials of the latter company explain plans in the following statement: "The International Smelting Co., which treats the concentrates of the Inspiration company, also smelts concentrates of the Miami Copper Co. This smelter has been shut-down since last March when Inspiration and other copper mines ceased production. Miami has continued production steadily at the rate of about 4,250,000 lb. per month. International has been receiving and storing concentrates of Miami. Under its smelting contract, International must return copper from these concentrates within a definite time. Thus far it has

been able to deliver copper due Miami from other stocks and has stored concentrates produced by Miami. Its storage capacity has become taxed, and, in order to make deliveries required by its contract, the smelting company has been obliged to start operations in order to treat stored concentrates of Miami. Copper represented by these concentrates has been reported from month to month as though actually produced, and smelting of the concentrates does not mean any addition to stocks that have been already fully reported."

SAN FRANCISCO SECTION OF THE INSTITUTE MEETS AT BERKELEY

The regular monthly meeting of the San Francisco section of the American Institute of Mining and Metallurgical Engineers was held on November 9 at the School of Mines building of the University of California at Berkeley. The hour from 7 to 8 o'clock was occupied in the inspection of the Mines building. James M. Hyde gave an interesting address on 'What a Young Engineer can do in the Business World'. The meeting was well attended by the students in mining engineering in the University. The meeting was in furtherance of the plan to increase membership by arousing the interest of the younger engineers.

ASSAYERS REQUIRED FOR MINT-SERVICE

The U. S. Civil Service Commission announces an open competitive examination for assayer on December 7. Two vacancies, one for duty in Washington, D. C., and the other for duty in San Francisco, each at \$2200 per year, exist. Appointees whose services are satisfactory may be allowed the increase granted by Congress of \$20 per month. Applicants must have graduated from a four years high-school course or have completed at least 14 college entrance units of work. In addition, they must have completed at least one year's course in general and analytical chemistry in an institution of recognized standing; and have had at least two years practical experience in analytical work, at least six months of which must have been in metallurgical analysis. Special credit will be given for experience in the assaying of gold and silver.

CHIEF CONSOLIDATED PAYS DIVIDEND

The Chief Consolidated Mining Co. paid a dividend of 5c. per share on November 1. This called for the payment of \$44,201, bringing the year's disbursements to stockholders up to \$176,804, and the grand total up to \$2,004,323. During the third quarter the company shipped 22,116 tons of ore, averaging 0.058 oz. gold, 33.276 oz. silver, 16.55% lead, and 1.10% copper. The metal production was 1142 oz. gold, 735,922 oz. silver, 3,270,749 lb. lead, and 3082 lb. copper. The average gross value per ton was \$40.69; smelting, freight, and sampling charges, \$18.55, leaving a net value of \$22.14 per ton, or a total of \$489,534. The net profit for the quarter was \$72,940. During the period a total of 10,654 ft. of development work was done in the Chief mine and 160 ft. in the Plutus mine, which adjoins the Chief Consolidated property and is controlled by the Fitch interests.

ACTIVITY AT VIRGINIA CITY, NEVADA

A report is current, but unverified, that three of the north-end mines, the Con. Virginia, Ophir, and Mexican, are to be merged under a single corporate ownership and that a cyanide mill of large capacity, at least 1000 tons, will be built in the spring to treat the low-grade ore of the upper horizons in these mines. The Mexican mill, operated jointly by these companies with the Union and Sierra Nevada, is treating 120 tons daily from the Con. Virginia. This ore is the product of selective and rather costly mining on the 2000-, 2100-, and 2200-ft. levels.

At Gold Hill the haulage tunnel of the United Comstock Mines Co. is more than 75% completed, lacking only some 1300 ft. between the Knickerbocker and Belcher shafts. Hard rock has impeded progress here and this section may not be finished before February 1. Hoar electric shovels are used in driving both breasts. Foundations for the mill buildings, covering five acres, are progressing and concrete is being poured at the rate of 125 yd. daily. A steam-heating plant, just installed, will ensure against freezing in cold weather. The mill will treat 2500 tons of ore daily and the coarse-crushing plant will crush 2000 tons in eight hours. A director of the company is authority for the statement that the ore from the lode will be mined and milled for a total maximum cost of \$2 per ton. In the Imperial mine alone 4,000,000 tons of mill ore has been blocked above the 400-ft. level. A 90-ft. cross-cut in the Trojan is said to have sampled \$9 per ton. The new town built by the company in American Flat, at the portal of the tunnel, is to be known as Comstock; a postoffice will be provided.

A number of properties on branch veins or cross-fissures are being developed. The Pittsburg Comstock, headed by H. G. Humphrey, vice-president of the United Comstock, has re-opened an old 600-ft. tunnel entering the mountain from the Jumbo road, above the Belcher on the foot-wall side of the lode and adjoining the Trojan. The tunnel will shortly cut the Bright Star vein, extending from the Trojan at a depth of over 400 ft. below the upper tunnel and glory-holes that produced high-grade ore. The tunnel cuts a foot-wall vein containing good mill-ore. The product of this mine can be sent at small cost to the United Comstock mill and the property will be opened later from the haulage tunnel of the latter company. In the Scheels workings of the Comstock Silver Mining Co. good mill-ore has been exposed in considerable quantity, together with seams and bunches of high-grade. The Scheels tunnel workings have been connected with the Scheels inclined shaft and a drift from the bottom station is being advanced to connect with the main Overland shaft, a 550-ft. incline extending to the Scheels boundary. The company's 10-stamp amalgamation mill on the Overland is to be used for a short time by lessees working on the adjoining Lager Beer. The mill, electric hoisting machinery, assay laboratory, buildings, and equipment of the Comstock Silver Co. are in excellent condition. George Drysdale, the manager, expects to begin treating ore as soon as the Overland shaft is repaired. F. W. Royer is consulting engineer.

Albert Burch, consulting engineer to Boericke Bros. of Philadelphia, has commenced a second sampling of the so-called middle group of mines. The work will involve driving cross-cuts to the foot-wall of the Chollar & Potosi, a long drift north into the Gould & Curry, and probably the re-opening of the old Gould & Curry tunnel, the deepest vein in this section of the lode.

PESSIMISTIC VIEW OF FUTURE OF MEXICAN OILFIELDS

In discussing the Mexican oil situation and its bearing on American oil production, Joseph P. Guffey, the Pittsburgh oil

operator, who recently returned from Mexico, is quoted as saying:

"The light oil reserves of Mexico amount to only 60,000,000 bbl. Before March 1, 1922, that country will become an unimportant factor in the oil-producing world. It is about time that the public woke up to the fact that America, and in fact the world, is now confronted with a most serious situation, due to the destruction of the major part of the light-oil field of Mexico by salt water and the menacing of the present small light oil-producing area of that country by water.

"This most unfavorable development in Mexican oilfields is benefiting and will continue to benefit all of the American oil producers. Great refining interests of America will have to depend more than they have for many years past upon American crude. Mexican light oil, when subjected to modern refining methods, produced a good volume of gasoline, kerosene, and lubricants; as a matter of fact, this grade of oil contained about 20% of the above-named valuable products.

"All of the bulk of Mexico's best grade has been produced from the Tampico-Tuxpam light-oil zone, a narrow strip running in a north and south direction from Dosobacas to Alamo. Practically all of the sections or pools located along that stretch of land have been exhausted of oil, salt water replacing it."

JAPAN CONTINUES TO PURCHASE ZINC

Japan continues the mainstay in the zinc-export trade of this country. In September for the sixth consecutive month Japan took by far the greatest proportion of our zinc exports. In the seven months ended with September shipments to Japan amounted to 2,242,016 lb., or 70% of this country's export trade in bars, pigs, slabs, etc., during that period. In September alone Japan took 98% of the total shipments, against 65% in August and July. France and the United Kingdom are still out of the market, not a pound having been exported to either of those countries this year.

THE TRAGEDY AT BRITANNIA BEACH

The latest reports place the death list in the flood, of October 28, at the Britannia mine, on Howe Sound, B. C., at 58; already 36 bodies have been recovered and 22 of the inhabitants of the town are still missing. It is estimated that 50 houses have been demolished and about 200 people are homeless. F. J. Donohue, general manager of the Britannia mine, stated that the company would rebuild the houses as soon as the wreckage can be cleared away. Many acts of heroism are reported, among which may be mentioned that of the two watchmen who were patrolling the creek and who easily might have got out of the way of the flood by climbing onto higher ground. Evidently, however, they preferred to try to reach the village to give warning to the inhabitants, and, being overtaken by the flood, were both drowned. This is the third serious disaster that has happened to the Britannia company and its employees within recent years. In the spring of 1915 a snowslide carried away the main boarding-house and eight other buildings, killed 54 men, and demolished the aerial tramway; while last February the 2500-ton concentrating plant, the first flotation plant to be erected in the Province, was destroyed by fire, fortunately without loss of life. The accompanying photographs show sundry scenes following the flood.

ARIZONA

Bisbee.—The Shattuck Arizona Copper Co. reports for the quarter ended September 30: total expenses, \$76,467; net development returns, \$20,857; interest received, \$9953; total receipts, \$30,810; net expense for quarter, \$45,657.

Photographs Taken at Britannia Beach, B. C., After the Recent Flood

Kingman.—High-grade silver-gold ore has been found in the main drift on the G. A. R. claim of the White Hills Mining Co. This ore is similar in character to the first ore discovered in the G. A. R. claim. Larger equipment has been installed and it is planned to sink to the 1000-ft. level. For several months the 40-stamp mill has been under repair preparatory to operation on the low-grade ores that is blocked-out.

Oatman.—It is reported that the No. 3 shaft of the United Eastern Mining Co. has reached a depth of 840 ft. Development is expected to be carried on from the 850-ft. level if the present favorable showing continues. The shaft at the Big Jim Claim has reached a depth of 660 ft. and has reached the water-level. The tram from the Big Jim to the United Eastern mill is nearing completion.

Development, which is now being carried on by the United Eastern in the No. 3 shaft, which is near the United Western property line, has renewed interest in the holdings of the latter company. The United Western is now offering a block of stock to raise money for taxes and incidental operating expenses.

Prescott.—L. N. Wombacher has taken a contract to sink a shaft for the Gold Leaf Mining Co. of Cherry Creek. Preliminary to sinking the shaft, new machinery is to be purchased. The Gold Leaf company's property adjoins, on the north end, the Logan property, where an 80-hp. boiler and double-drum friction-hoist now are being installed. A 10-stamp mill is in process of erection at the Logan, where engineers estimate there is ore to the value of \$160,000 blocked-out above the two upper levels.

CALIFORNIA

Bridgeport.—The Pittsburg-Liberty gold mine in the Masonic district has been leased to H. C. Barnes and associates. The entire mineralized zone surrounding the mine will be prospected by the new owners.

Cedillyville.—E. M. Robinson is drifting in the deep gravel bar below the junction of the East and South Forks of Salmon river. He has completed the wing-dam which turns the river toward the bank opposite his work and has built a long flume. Harvey Bowerman is taking ore from a seam on his

Wild Irishman claim which adjoins the King Solomon mines at Canyon mountain.—Wallace McAnslan and William McClave have moved from upper South Fork to Canyon mountain and are working on a quartz prospect there.—Henry Ball is sawing lumber for his flume at the Jefferson Consolidated placer mine. He will begin laying flume and re-setting his pipe-line soon.—Daniel O'Shea is extending the tunnel at the Bowerman prospect on South Fork near Gibson gulch.—J. M. Lax & Sons will resume operations at the Root & Solsburg hydraulic mine. Recent rains have increased the supply of water in the creek.

Downieville.—The Sierra Buttes Mining Co. has excellent prospects in its No. 7 tunnel. Recent work has opened new ore which will be developed. Arrangements have been made with the owners of the Bigelow property, which adjoins the Sierra Buttes on the west, whereby the former will be developed through a tunnel on No. 9 level.—Ore from a 12-ft. vein is being milled in the Wheeler mill by Hughes & Cameron.

Grass Valley.—More than 50 tons of high-grade ore from the Julia Ross mine has been sacked and shipped to the Dull mill. The shaft from which the ore was taken is now 65 ft. deep.

Hayden Hill.—H. P. Anderson has prospected a north and south gold-bearing vein for 1250 ft. on the surface. In one pit he obtained ore assaying \$12 per ton.

Redding.—The old smelter town of Keswick is rapidly fading away, as the Mountain Copper Co. shifts the scene of its activity to Matheson, the terminal of the new tram-line from the Hornet mine. Matheson is a new town on the Southern Pacific railway, three miles north of the site of Keswick; it will be the shipping point for the company's ores. Twenty of the 32 towers of the tram-line have already been erected.

San Francisco.—The annual meeting of the California Metal and Mineral Producers Association will be held at its offices in the Merchants National Bank building, in this city, on Wednesday, November 16, at 10 a.m. A full attendance is desired. Members who will not be present have been requested to execute and forward proxies at their earliest convenience.

COLORADO

Breckenridge.—Mines on Farncomb hill will be operated continuously this winter, and supplies have already been hauled in to last until late spring. The hill is famous for its rich wire gold, and, judging from the number of prospectors working in shallow shafts, new discoveries will result.—A shipment of sacked-ore was forwarded to the Leadville smelter recently from the Harriman lease on the Guyot; the ore was rich in silver.

Central City.—The Buffalo Chip mine has been leased and a contract let for installing a hoist and a compressor. The shaft is 175 ft. deep, with ore in the bottom level sampling 28 oz. silver and 0.63 oz. gold.—Concentrate assaying \$50 per ton have been shipped from the Polar Star mill to the A. V. smelter at Leadville.

Cresco.—Five carloads of ore have been shipped to the A. V. smelter by the Wabash M. & P. Co.; one car came from the Solomon group, operated by Del Norte men; and the Hether Leasing Co. has shipped \$50 ore to the Leadville plant.—Operations have been resumed on the Manitoba and Ontario group by the Manitoba Leasing Co. Shipments from this Sunnyside property will start shortly on ore already blocked out.

Cripple Creek.—Directors of the Cresson Consolidated at a meeting held at Colorado Springs recently took no dividend action. It is expected that no dividend will be paid

until the question of taxes on excess profits has been determined. Rich discoveries have recently been made at the 1600- and 1700-ft. levels; new shoots under development are reported sampling 6 and 7 oz. gold per ton. Between the 1100- and 1200-ft. levels an orebody 125 ft. wide by 200 ft. long is sampling \$12 to \$15 per ton as broken. For the three last days of October the average daily production, shipped to the Golden Cycle mill at Colorado Springs, was 250 tons.

The Vindicator company has started an extension of the Roosevelt tunnel, from its present terminal at the Portland, to cut through the Vindicator No. 2 shaft. Sinking has also been resumed from the station the 2000-ft. level of the Vindicator.

Idaho Springs.—The Silver Cycle Mining Co., recently organized, is cleaning out the Wyoming Valley tunnel preparatory to extending the bore. The tunnel will unwater the Gold Medal group and Silver Age mines.

Leadville.—In Big Evans gulch the Dolly B. shaft is being re-timbered for the main air-shaft of the Yak tunnel.—The Ruby & Klach group in the Weston Pass district are active; high-grade silver-lead and high-grade zinc carbonate ores are being mined.

Ouray.—The mill-force at the Hidden Treasure has been increased and the plant is now operating at capacity; this will continue through the winter months.—A recent 20-ton shipment made by lessees on the Guadalupe is reported as netting \$2100. Another shipment leaves the lease soon.

IDAHO

Coeur d'Alene.—The Jim Blaine Silver Syndicate recently cut, at 150 ft., a blind vein in which galena has been found at intervals. This vein was unexpected, the first, or Jim Blaine vein, not having been expected until the tunnel had been driven 450 to 500 feet.

Homestead.—The Copper Syndicate enterprise is developing its ground through a 2500-ft. tunnel, by means of cross-cuts and a winze. The vein is 25 ft. wide and contains some silver, gold, and copper.

Moscow.—At the east end of Moscow mountain, 10 miles north-east of here, placer mining is being carried on in a newly discovered district. The placer is on the homestead of George Saad, of Troy; the pay-dirt was discovered last summer by E. Williams, an old-time prospector. Five shafts have been sunk and dirt panned from these shafts goes from 15 to 55c. per pan. Black sand yielded \$5.80 per ton when washed. A flume is being put in and 700 ft. of 10-in. steel pipe has been purchased and is on the ground. The fall and winter will be devoted to preparing to sluice the dirt next spring, when the first high water comes.

Orogrande.—Three feet of high-grade ore has been disclosed, according to Ralston McCaig, manager of the Summit Flat mine. The disclosure is in No. 2 vein on which a depth of 200 ft. has been attained. The width of the body has increased steadily from 18 in. Samples taken some time ago contained \$21 gold per ton.

Porthill.—The Idaho Continental Mining Co. is shipping about 20 tons of ore daily and has about 1800 tons of concentrate on the dump ready for shipment.

MICHIGAN

Houghton.—Eleven furnaces are now in commission in the Lake district, including eight at the Calumet & Hecla smelter, two at the Michigan, and one at the Quincy. Production is approximately 27% of 1916, a normal year. Only 16% of the normal working mines are operating and 25% of the men are employed. Production in October was approximately 7,000,000 lb. This compares with a normal monthly production of 22,800,000.

Progress is being made with the rather unusual geological survey being conducted by a number of prominent geologists for the Calumet & Hecla Mining Co. The purpose of the investigation is to discover, if possible, the origin of copper and how it came to be laid down in native form in lodes or veins, rich in some portions and barren in others. The results to date, however, may be described as 'negative'. That is, if the survey were to stop now, the data available would enable a company seeking new copper deposits to determine whether to proceed with the work or stop it altogether when certain combinations of conditions were met. No results have yet been obtained, however, that would lead the miner directly to the copper in the lode without likelihood of failure, and it is toward that goal that the survey will be continued. The work that has been done to date is distinctly encouraging and it has more than justified the expenditure. It has overturned some pet theories and established facts which may be depended upon. A big saving will be made in the long run as a result of this research.

Not more than 1000 ft. of drifting remain to be done before the 81st-level haulage-way, which will serve Calumet &

Helena plant of the American Smelting & Refining Co., is quoted as saying: "It has been rumored that the American Smelting & Refining Co. has withdrawn from the custom-ore business in the Butte district. While it is true that we have found it necessary to place an embargo on the very low-grade highly-silicious ores, we are still in the market for those ores which will stand the necessary treatment charges".

The showing of copper ore on the 2200-ft. level of the Black Rock mine of the Butte & Superior Mining Co. has improved within the past week, according to reports. Ore showing in the face of the drift is 6 ft. wide and will average 4% copper with as many ounces of silver. This face is on one of three bands of copper ore uncovered by cross-cutting on this level; the bands are 8 to 10 ft. apart, and they will be cross-cut when drifting has progressed farther. Thus far only one band lying alongside the foot-wall has been opened, aside from the cross-cutting of the three when the copper vein was first opened on the 2200-ft. level, and as these two other bands show a width of about 3 ft. each, the prospects in connection with the development of this fissure on the

Terminal of the Government Railroad at Anchorage, Alaska

Hecla's conglomerate shafts, will be completed. No. 12 shaft, its southern terminal, will be used as a supply shaft and for the use of the miners, while Red Jacket shaft, the northern terminal, will become exclusively a hoisting shaft. The intervening shafts will be abandoned, eliminating the cost of maintaining expensive surface-plants, and the mining of the lode will be done from the haulage-way. This drift will lessen the cost of deep mining.

As expected, copper shipments out of the Lake district in October were the heaviest of the season. A total of 10,840,000 lb. was shipped by boat, and in addition it is estimated 2,000,000 lb. went out by rail. October water shipments compare with 7,028,000 lb. for September, 5,176,000 for August, and 8,322,000 for October 1920. October shipments by boat bring the total for the season of navigation up to nearly 41,000,000 lb. Estimated rail shipments are 10,000,000 lb., making total deliveries since May 1, 51,000,000 lb. Water shipments by months have been as follows: May (including a few days in April), 5,310,000 lb.; June, 5,858,000; July, 6,536,000; August, 5,176,000; September, 7,028,000; October, 10,840,000. The increase shown by September and October shipments is attributed largely to an improved demand for the metal rather than any particular desire to take advantage of lower freight-rates by the water route.

MONTANA

Butte.—W. J. O'Connor, assistant manager of the East

2600-ft. level are promising. A copper-ore stock-pile now is being reserved at the concentrator. About five months work will be required before the cross-cut now being driven on the 2600-ft. level reaches the copper vein, which appears at this time to be a 'northwester', in distinction from an east and west vein, as judged from its strike, and doubt is expressed that it is a branch of the Rainbow. Cross-cutting on the 2600-ft. level will place the Butte & Superior comparatively close to the ground of the Butte-New York, which it controls.

NEVADA

Barcelona.—Motor-trucks are hauling concentrate to Tonopah from the new flotation mill of the Con. Spanish Belt Silver Mining Co. The mill is operating two shifts and is producing daily 2000 lb. of concentrate from tables and 1000 lb. from the flotation machines.

Candelaria.—Meetings held in New York, Chicago, and Reno in the past ten days have resulted in an arrangement by which the Rochester Silver Corporation, operating at Rochester, Nevada, will advance funds for building a mill to treat the product of the Candelaria Mines Co. The Candelaria directors some time ago authorized an issue of interest-bearing notes to raise funds for a mill. The Rochester company will provide the necessary money up to \$200,000, and in its Rochester Combined mill it has new mill equipment that can be utilized in the Candelaria plant. C. D. Kaeding, manager and consulting engineer, estimates the Candelaria reserve at \$3,436,000 gross value. Mill-ore,

chiefly above the 200-ft. level in the Lucky Hill mine, contains 14 oz. silver and \$1 gold per ton. Dumps and stope fills contain 9.7 oz. silver and a small quantity of gold. A branch of the new Mineral County power-line will be extended to the Candelaria plant.

Cortez.—The old Fitzgerald mine, forming the most easterly part of the Con. Cortez Silver properties, has been reopened above the bedded quartzite zone, in the upper limestone, and recent sampling here is said to give promise of a large tonnage of good mill-ore. This area was worked when only high-grade ore could be mined with profit. The double raise from the Arctic tunnel, 360 ft. below the Garrison adit, is advancing in the main porphyry dike that cuts the mountain. Two of the secondary fissures in the limestone, containing high-grade primary sulphide ore, were cut by the lower adit.

Rochester.—From a two-week clean-up at the Rochester Silver Corporation mill a bullion shipment valued at \$40,407 was sent to the Mint. This is the largest shipment in more than two years. Frederick Sawyer, the secretary, reported current assets \$274,617 and liabilities \$33,521 at the close of September.

Tonopah.—The Royston mining district, 28 miles north of Tonopah, has been organized, embracing a part of the old San Antone district. High-grade silver ore was found on the Betts lease on the Hudson property in September. A small shipment sent to Tonopah assayed 944 oz. silver and \$25 gold per ton. The Hudson Mining & Milling Co. has granted 13 leases. W. H. Royston, for whom the district is named, is manager for the Hudson company and superintendent of the Tonopah Belmont mill. The Hudson company is controlled by the Walker brothers, of Salt Lake City.

Engineers of the Tonopah Mining Co., as the result of recent sampling, estimate the reserve in the Tonopah property at "more than a year's supply in excess of earlier estimates".—The West End Con. is driving a raise in the Tonopah 76 ground from the 800-ft. level, indicating that this work is nearing the vein. The company is developing its recently acquired Mabel group at Garfield, north-west of Mina.—Deep levels of the Tonopah Extension are opening ore of great width in the Victor territory, notably on the 1680- and 1760-ft. levels.—The latest bullion shipment from the Tonopah Belmont, from the usual 15-day clean-up, was valued at \$124,500.—Tonopah Divide in September shipped to the Belmont mill 1515 dry tons assaying \$29.05 per ton, total gross value \$51,200. Similar output was maintained in October. The sinking-hoist has been moved to the 1100-ft. station. A cross-cut is advancing south on the 800-ft. level, near the Gold Zone boundary, to prospect the gold-bearing zone opened by the main drift.

UTAH

Alta.—The South Hecla Mines Co. will undertake extensive development of its 1300-acre tract during the coming winter. In the Alblon property the adit is in about a mile and is nearing what is believed to be the downward extension of important orebodies found on upper levels some years ago. Most of the development work will be carried on in that part of the property. During the summer, mines in Alta are troubled with heavy flows of water, but during the winter they are comparatively dry and in the best condition for exploratory work.

American Fork.—An important find has been made in the Silver Wave claim, under lease to the American Leasing Co., of which Karl Perlin is manager. Some time ago the Globe Consolidated Mining Co. was given permission to drive a long tunnel from the Holden tunnel through the Silver Wave claim, to gain access to ground belonging to the Globe company. This tunnel has been driven at the rate of 5 ft. per day, and recently its course was directed across

the Read & Benson lime-beds, which have been highly productive in the past. A full face of rich copper-gold-silver ore was cut in driving the tunnel. Samples of the ore show chalcopryite, chalcocite, and silver sulphide.

The Silver Contact Mining Co. has let a contract for driving a tunnel at its property, about 7 miles up the canyon. In 1918 a shaft was sunk to a distance of 45 ft. and bunches of high-grade ore were found. A tunnel was started 150 ft. below the shaft, and after being driven 100 ft. was stopped.

Bingham.—Fire has again broken out between the 1400 and 1500-ft. levels of the Utah-Apex mine, and gas has penetrated some of the workings of the Utah-Consolidated mine. The fire started in 1917 but was controlled. Additional bulk-heads will be constructed in both mines at once.

Box Elder County.—The new tunnel being driven at the Vipont Silver Mining Co. is now in a distance of 650 ft. It is being driven forward at the rate of 200 ft. per month. The portal of the tunnel is but 200 ft. distant from the concentrating plant and will reduce tramming distance about 2200 ft. It is expected the tunnel will enter the mineralized zone at a distance of 1800 ft. from the portal. The ore contains native silver and silver sulphide; it is a replacement in a silicious black limestone. Concentrates are shipped 26 miles to Oakley, Idaho, the nearest rail point. About 250 men are employed at the property; it is one of the largest producers in Utah at present.

Eureka.—Shipments of ore during the week ending October 29 totaled 168 cars, as against 172 carloads the previous week. The Tintic Standard shipped 66 cars; Chief Consolidated, 48; Victoria, 11; Dragon, 9; Eagle & Blue Bell, 7; Iron Blossom, 7; Centennial-Eureka, 6; Swansea, 4; Colorado, 3; Alaska, 2; Bullion-Beck, 2; Tintic Drain Tunnel, 1; Gemini, 1; and Eureka Mines, 1.

The Tintic Milling Co. is again taking ore from the Dragon mine, under lease. Production was discontinued some months ago on account of a cave. About one carload of ore per day is being sent to the Tintic mill, according to Richard Eataugh, who is superintending the mining operations in the Dragon property for the Tintic Milling Co.

The Zuma Mining Co. has let a contract for sinking the shaft from the 1000 to the 1200-ft. level. F. J. Fennell, manager of the property, will start exploratory work at that depth.

The Iron King Mining Co. has suspended shipments of iron ore to the American Smelting & Refining Co., owing to a surplus of that type of ore at the Murray and Garfield smelters. B. F. Grant, who is in charge of that portion of the mine under lease to the A. S. & R., has reduced his force considerably, and those who are retained on the payroll have been put on development.

Logan.—The Mineral Point Mining Co., owning claims in East canyon, has driven two tunnels; the upper one is in a distance of 140 ft. and the lower a distance of 100 ft. An orebody encountered by the upper tunnel assays 22.75% copper, with small quantities of gold and silver. The lower tunnel, at a distance of 75 ft. from the portal, struck a vein, assays of which show as high as 42.6% copper. Andrew Madsen is in charge of the property.

Park City.—Ore shipments for the week ending October 29 totaled 2140 tons, as compared with 1886 tons the preceding week. The Judge allied companies shipped 937 tons; Silver King Coalition, 722; and the Ontario, 481.

WISCONSIN

Benton.—The Block-House Mining Co. has combined with the McGulre-Sally Waters interests and a surface rig will be provided without delay. The mine shows extensive deposits of smithsonite at the 60-ft. level, while in the lower openings, at a depth of 110 ft., four 'blankets' of high-grade zinc

ore are shown.—The sale of zinc tailing has assumed formidable proportions. The material is now used largely in surfacing highways. The Carroll Construction Co., of Milwaukee, has contracted the tailing at the Fox mine. A spur has been built to the mine, and shipments are now being made at the rate of 15 cars daily.

Livingston.—The Vinegar Hill Zinc Co. has resumed output at the Dale mine after a shut-down lasting more than a year. A force of 50 men is at work. The crude-zinc concentrate is shipped to the National Separators, at Cuba City, where it is treated and reduced to high-grade blende. The sulphur is burned off and used in the manufacture of sulphuric acid.

Mineral Point.—Shipments of zinc oxide from the works of the Mineral Point Zinc Co. are steady. Demand is good.

Platteville.—Sales of high-grade electro-magnetic separator blende have been made for the first time in several months, and buyers representing the larger smelter concerns are in the market for ore. Local offerings for 60% zinc ore were made on a base price of \$27 per ton, and some sales brought a top price of \$30. Lead ore advanced in price steadily, the latest quotation being \$60 per ton, base price, standard 80% assay. Premium-grade lead-concentrate obtained in wet concentration of zinc ore, as by-product, brought as high as \$62.50 per ton. Sales were more liberal and prospect work was greatly accelerated at all points in the field, as a result of the higher offerings. A considerable tonnage of both high-grade zinc ore and milled lead ore was carried over by many of the active producers when the shut-down became general; these are now willing to sell in order to realize on their holdings sufficiently to resume operations. A demand has sprung up for repair-parts, renewals, and new mining machinery, and several properties are being equipped. Some new mill building has been contracted as well.

The Block-House Mining Co., which is operating the Schroeder mine and mill, is engaged in constructing a new mill on the Goke tract, one-fourth mile to the east. The two mines are on the same big east and west range.—Savage-Menke Mining Co., prospecting on the Dixon range west of this city has installed power, pumping, and milling machinery, and lead ore is being prepared for market.

BRITISH COLUMBIA

Barkerville.—A. Sanders has uncovered a 30-ft. belt of oxidized pyrite, on Proserpine mountain, that carries numerous quartz stringers. The oxide shows well in the pan, and samples have assayed from \$380 to \$450 per ton. At a depth of only a few feet the ore is solid sulphide. A trial shipment of the oxidized ore is to be made.

New Denver.—Thomas Avison and Ben Killsall, who have a lease on the Alpha mine dumps, have worked over the upper dump, concentrating the picked ore in a coarse jig, and have 45 tons of concentrate that is being hauled to Silverton for shipment to Trail.—Lessees at the Standard mine are drawing stope-fillings and breaking down good ore at isolated points in the mine. The flume is being repaired and the mill will be started shortly.

Prince Rupert.—The tramway connecting the Pugsley mine with the mill of the Surf Inlet Mines, Ltd., is now nearly completed. The Pugsley ore is of a much higher grade than the Surf Inlet ore, and operations should show a good profit in the future.—Eastern capitalists have bonded the Silver Bar group for \$75,000 and the Waverley group for \$30,000. Both groups are situated on the Kitsault river, in the Alice Arm district.

Stewart.—The case of Pat Daly v. R. K. Neill, in which the plaintiff claimed a one-fourth share in the Premier mine, valued at \$1,960,000, has been settled out of court, Daly being contented to receive \$15,000.

Victoria.—A deputation, consisting of J. J. Warren and T. W. Bingay, of the Consolidated M. & S. Co.; Valentine Quinn, of the Granby M. S. & P. Co.; S. S. Fowler, of the Bluebell mine; and G. P. Jones, of the Nickel Plate mine, waited on the Provincial government to request consideration of the method of assessing taxation in the mining industry, particularly with regard to a greater allowance for depletion, depreciation, and development.

The announcement is made that the zinc production of the Trail smelter of the Canadian Consolidated Mining & Smelting Co. this year will be the largest in the history of the plant. The output will be nearly 50% above that of last year. A market has been found in the Orient, important shipments having been made to the East recently, thus relieving the pressure of surplus stock. Improvement in copper-market conditions in British Columbia is also noted. A large concentrating plant is proposed for Anyox, the smelting centre of the Granby Consolidated Mining & Smelting Co. There is the new mill of the Britannia Mining & Smelting Co., Britannia Beach, as well as the proposed new mills at the Sunloch and Old Sport mines, Vancouver Island, to be constructed by the Consolidated Mining & Smelting Co., Ltd. Besides, there is no doubt that operations will be renewed on a substantial scale at the Copper Mountain mine, Princeton, while the Iron Mask at Kamloops and other properties now idle will become active.

MEXICO

Chihuahua.—The past week has witnessed a continuation of general activity in the mining industry. Each day additional mines are added to the list of shippers. Properties which have been idle for several years are being opened again and shipments are being resumed. All of the mining agencies report renewed activity in the way of new filings.

At the Chihuahua mining office, M. D. Murray has recorded the Watson group, comprising 78 contiguous claims situated in the Torreon district; also the Watson No. 1 group in the same vicinity, composed of 38 pertenencias. These properties are situated near the San Jose mines, which produce lead, silver, and copper.—At Ocampo, Enrique Diaz Duran has made application for titles to the Progreso group of 24 mining claims, in the Coneheno district contiguous to the Veracruz and Orizaba mines.—At Ciudad Guerrero, Jose Moreno and Juan Molinar have recorded the San Andres, a promising prospect of 10 adjoining claims in the mountains about 10 miles north of Madera. In the same district J. R. Corral has located the Santo Nino mine, which carries gold, silver, and lead.—At Parral, Charles P. Holter has made application for titles to a group of 10 claims in the municipality of Zaragoza near the Santa Fe and La Estrella mines.

Durango.—Simultaneously with the resumption of operations at the Asarco smelter in the Velardeña district the producing mines which have been idle for the past year are again opening, not only in that immediate vicinity but throughout the whole State. Stimulated by the price of silver, it is reasonable to suppose that by the first of next January many silver mines will resume.

Nacozari.—William Jensen, who recently acquired title to the El Trigo mine in the Sahuaripa district, will complete a tunnel that will cut the ore below the level of the old workings. He plans to install a Pelton wheel and a five-stamp mill. The ore averages 3 oz. in gold. The tailing from amalgamation will be stored for tabling and cyaniding.

W. F. B. Berger, of New York City, is making a trip of inspection to the Lampazos mine, owned by the Bank of Sonora. This mine was worked until 1907, having produced two million ounces of silver. An estimate will be made of the cost of unwatering the mine for an examination.

J. W. Reynolds and M. L. Buckley, of Pinar, have

acquired several important claims adjoining the Zarape concession of the Moctezuma Copper Co. and have organized under the name of the Pilares Extension Mining Co. A tunnel is being run from the west end of the property to tap the old workings. Among the claims acquired are San Francisco de la Fortuna, La Mestiza, and San Francisco No. 2.

H. C. Carlisle and H. C. Beauchamp have just completed a trip of inspection through the Moctezuma district and have taken options on several properties; they have also located some good ground for denouncement later. Some of the properties optioned are the San Jose, owned by George Moore, the San Juan of Miguel Antunez, and the Exito in the El Tigre district.

ONTARIO

Cobalt.—There will be no general resumption of work this fall at the closed-down mines in the Cobalt district. Mine-owners believe it will be to their advantage to wait until next spring before re-opening the present idle mines. There are nine companies producing, these being the Nipissing, Mining Corporation, Coniagas, O'Brien, La Rose, Kerr Lake, Bailey, Hudson Bay, and Chambers-Ferland. Production is small and intermittent from the Kerr Lake and the Chambers-Ferland, while the Hudson Bay is carrying on milling operations in order to dispose of all the broken ore in sight, preparatory to definitely shutting down, due to exhaustion of the ore.

In the South Lorrain district, the Keeley is producing at a rate of about 120,000 oz. per month from a high-grade ore-shoot entered two months ago. It is probable that this record will not be maintained, and that within a few weeks the output will return to normal of about 60 tons of ore daily, containing an average of 30 oz. silver per ton.—A mineralized body, containing \$5 per ton in gold, is being explored in the Larder Lake district by the Crown Reserve Mining Company.

Kirkland Lake.—The property known as the Jerred claims, comprising 196 acres adjoining the King Kirkland, has been taken over on option by C. F. Jordan, president of the King Kirkland. Several promising gold-bearing veins are in evidence and exploration is in progress.

Development at the 900-ft. level of the Kirkland Lake mine has placed a considerable quantity of high-grade ore in sight. The mill is treating about 4000 tons of ore per month.

Matthewan.—At the Thesanus mine on the Montreal river, 20 ft. of ore stated to carry free gold has been opened in a cross-cut at the 100-ft. level.

Porcupine.—The Dome Mines during September produced nearly \$250,000, the mill having operated at 90% capacity, treating over 30,000 tons of ore with a recovery approximating \$8 per ton. This is the highest average mill-head so far obtained.

The management of the Hollinger Consolidated has decided to sink another big central shaft of at least six compartments to a depth of approximately three-quarters of a mile. There are now 1970 employees on the payroll and upward of 100 machines in operation underground, and an average of from 3800 to 4000 tons of ore is being taken out every 24 hours.

At the Premier Paymaster two large return-tubular boilers of about 150 hp. capacity have been installed, giving the necessary power to sink to the 800-ft. level. A large ore-body has been opened at the 200-ft. level and it is proposed to develop it at greater depth.

West Shining Tree.—Good results have been accomplished by development at the White Rock, where a vein has been traced on the surface for 2600 ft. A shaft has been sunk for 65 ft. at which depth the vein was tapped by cross-cutting. Being drifted upon it widened to 6 ft.; it is stated to carry \$12 ore.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Owen Letcher has been touring India.

C. J. F. Galloway is on his way from Sarawak, Borneo, to England.

R. B. McGinnis, of San Francisco, has moved to Virginia City, Nevada.

George A. Camphuis has moved from Arivaca, Arizona, to Los Angeles.

Harold Borchsenius is with the Standard Oil Co., at Tupman, California.

Arthur W. Jenks is conducting mine examinations in Northern Ontario.

George Fischer has moved from Klamath Falls, Oregon, to Oakland, California.

W. A. Ray was married to Miss Minnie Rindfleisch, of Denver, on October 26.

R. C. Gemmell and D. D. Moffat have returned to Salt Lake City from Arizona.

Hector McRae, of St. Louis, Missouri, expects to go to London at the end of this month.

A. L. Reese, chief chemist to the United Verde Copper Co., at Clarkdale, Arizona, is in San Francisco.

D. M. Drumheller, Jr., has opened offices as consulting mining engineer in the Peyton building, Spokane.

W. F. Hayden, chief engineer for the Caribou Placer Co., near Seda Springs, Idaho, was at Salt Lake City recently.

Frank J. Morehouse, who is in charge of the Silver Reef Consolidated Mines Co. at St. George, Utah, is in New York.

W. H. Landers, recently of Charleston, West Virginia, is with the Clinchfield Products Corporation, at Erwin, Tennessee.

R. B. Lamb wishes to make public the fact that he is not associated with the promotion of the Gem Mining Co. of Colorado.

Mat. Sample, mine superintendent of the Chile Exploration Co. at Chuquicamata, is visiting mining districts of the West. He will return to Chile in December.

J. H. Saville, assistant manager for the Pyrites Co., at Wilmington, Delaware, sailed on the 'Olympic' on November 5 for Southampton. He expects to spend a few months in England and on the Continent.

Stephen L. Kaffer, who has been chief engineer for the past six years at the Phelps Dodge Corporation's Burro Mountain Branch property, is now in the sales department of the Mine & Smelter Supply Co. at El Paso, Texas.

Obituary

William Hatfield, a well-known mining man of Utah, died at his home in Salt Lake City on October 31. He was born in England 73 years ago, and came to Utah when a boy of 16. He was attracted to the mining business and is credited with being the first man to find ore in the Bullion-Beck and Swansea mines in the Tintic district. Later he operated the Snowflake mine in that district, and then became interested in the Alta district. He was one of the best-posted men in the State on Tintic and Alta mining properties, and at the time of his death was heavily interested in Tintic mines. He is survived by his widow, three daughters, and two sons.

THE METAL MARKET

METAL PRICES

San Francisco, November 7

Aluminum dust, cents per pound.....	05
Aluminum sheets, cents per pound.....	00

EASTERN METAL MARKET

(By wire from New York)

November 7—Copper is more active and stronger. Lead is quiet and firm. Zinc is more active and higher.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 flos) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE REWARD OF THE COPPER PRODUCERS

What does the average man know about copper? Probably only that two small round pieces of it with a bust of Lincoln on one side and a few words on the other will buy a newspaper. Perhaps that it clutters up his pocket and gets in the way of his more important small change. Maybe even that it is used in making some kinds of wire, or, in this day, to make kettles suitable for home brewing. Unless he is connected in some way with the business of copper mining, manufacturing, or marketing it is unlikely that he knows much more about it than that. But there really is much more worth knowing, says the "Chicago Tribune".

For instance: In 1895 the production of copper was only 380,000,000 lb. Then the expansion of the electrical industry, and later the Spanish-American war, the Boer war, the Russo-Japanese war, and the Balkan wars rapidly increased the demand and output. Between 1895 and 1918 production jumped to 1,928,000,000 lb. per year. World war demands raised it to 2,500,090,000 lb. in 1918. New mines were opened and mining and refining processes improved. Early in 1919 there was 1,000,000,000 lb. surplus stored in the United States. At the beginning of 1920 it was worth 19 cents per pound. At the end of the year it was worth 12½ cents.

Business was bad. Thousands of miners were out of work. Millions of dollars worth of mines, smelters, and factories were idle and deteriorating. Did the men in charge of this bad business sit down and cry, or wait for Government help? They did not. Did they protest that they had been unfairly treated because while they were selling their product at high prices for war purposes substitutes had been invented for peace purposes, advertised and made popular in many fields where normally copper would have been used? They did not.

The copper industry started out to learn all the disadvantages and possibilities of the situation. It made a survey which took a year, and the results of which filled seven big volumes. It covered the copper and brass industry completely from 1895 to date. It got all available information on substitutes, uses, sales, advertising, etc. Then it organized the Copper and Brass Research Association to study better and cheaper ways of mining and refining, and learn more practical uses of copper. Now it is preparing to tell the world all the advantages of copper and brass for hinges, door-fittings, plumbing fixtures, cooking utensils, roofing, gutter-pipes, screens, and a thousand and one things as yet unknown.

It will educate the public to use copper—to demand copper. It will make a market. It will prove to the buying public that copper goods of some kind are needed in every home and every business. When they have done, copper will be valued for a thousand uses where now it is valued for one. That will be good for the copper trade, the manufacturer, the sales agency, and the consumer. That is good business. That is the kind of fighters 1921 will reward.

MONEY AND EXCHANGE

Foreign quotations on November 7 are as follows:

Foreign quotations on November 7 are as follows:	
Sterling, dollars:	Cable 3.94
	Demand 3.94½
Franc, cents:	Cable 7.43
	Demand 7.45
Lira, cents:	Demand 4.20
Mark, cents: 0.40

Eastern Metal Market

New York, November 2.

A fairly optimistic tone pervades all the markets; it is more prominent in some than in others.

Demand for copper is again better and sales have been fair.

The tin market is quiet but firm and steady.

Buying of lead is moderate; the price shows no signs of change.

Zinc is the weakest market; demand has subsided.

Antimony continues to decline.

IRON AND STEEL

New buying has been light the past week, but several steel companies found bookings in October better than in any other month this year, made up largely of light products such as pipe, sheets, etc.

Pig-iron production in October increased beyond expectations, being the largest since March and representing a gain of 43% upon the low figure of July. As wired to 'The Iron Age' from all districts on November 1, the returns make a total of 1,240,162 tons, or 40,005 tons per day, against 985,529 tons in September, or 32,850 tons per day. The increase over September is about 22%. Seventeen furnaces blew-in and three blew-out in October, a net gain of 14; the 96 furnaces in blast on November 1 had an estimated capacity of 43,500 tons per day, as against 35,650 tons per day for 82 furnaces one month previous.

COPPER

For a few days last week it was possible to buy electrolytic copper in limited quantities at 12.62½c., New York, or 12.87½c., delivered, but this has disappeared, and it is believed that nothing less than 13c., delivered, can now be done. At the latter price considerable business amounting to a fairly large tonnage, is reported to have been done late last week and early this week; one seller reports that inquiries are larger than in a long time. The feeling prevails that a steady business is to develop in the near future and that the market is in for a season of healthy but not spectacular business. Sales for the month of October are estimated at not less than 60,000,000 lb. and export business is calculated to have been less than in September.

TIN

The past week has been one of the most inactive for a long time. One explanation is the fact that because of the threatened railroad strike, consumers of Straits tin not only bought fairly freely for spot delivery but accumulated supplies from warehouses. This has eliminated the spot demand for the present. There has been a little business in future shipment from the Far East, but less than in some weeks. October statistics show that deliveries into consumption were 2280 tons, with 1319 tons in stocks and 650 tons landing on October 31. Spot Straits tin was quoted yesterday at 28c., New York, or ¼c. under that of a week ago. Strength in sterling has been a factor in maintaining quotation at 28 to 28.50c. London prices are steady, or only £1 per ton under those a week ago, with yesterday's quotations at £155 10s. for spot standard, £157 15s. for future standard, and £156 for spot Straits.

LEAD

This market continues its steady course, devoid of features but characterized by a fairly steady demand which absorbs available supplies fairly promptly. Quotations are unchanged, that of the leading interest standing at 4.70c., both New York and St. Louis, while in the outside market they are 4.70c., New York, and 4.40 to 4.45c., St. Louis.

ZINC

A marked lull in demand is reported; and, as a consequence, a softening in prices. While the railroad strike threat was in the air and before, demand from galvanizers was brisk, but they evidently covered their needs, at least for the early future. Evidently prime western can be bought as low as 4.55c., St. Louis, or 5.05c., New York, for early delivery, but it is stated that only second-hands will entertain orders at this level, practically all producers adhering to a minimum of 4.60c. or even higher.

ANTIMONY

There has been a further easing in values until the metal is now available at 4.75c., New York, duty paid, for November delivery, with spot held at 4.80c. and jobbing lots about ¼c. higher.

ALUMINUM

Although the leading interest continues to quote virgin aluminum at 24.50c., f.o.b. plant, it is reported that it is willing to meet or has met importers' quotations of 17 to 18c. per pound, New York, duty paid. Rumors of large sales recently have not been confirmed.

ORES

Tungsten: Conditions are unchanged and quotations nominal in an inactive market at \$2.50 per unit and higher, depending on the grade, delivery, etc.

Molybdenum: The market is devoid of activity or feature, with quotations nominally unchanged at 50c. per pound of molybdenum sulphide in regular concentrates.

Manganese: There is an entire absence of business and quotations are still nominal at 20c. per unit, Atlantic seaboard, for high-grade foreign ore.

Chrome: No demand is reported and hence quotations are nominal at \$20 to \$26 per net ton, c.i.f. Atlantic ports for foreign ores, standard quality, depending on analysis.

FERRO-ALLOYS

Ferro-manganese: No demand at all is reported by British or American sellers, who still quote on a basis of \$58.35, seaboard, for either alloy. Production in the United States in October was 3902 gross tons.

Spiegeleisen: A sale of 200 tons is reported at about \$25 to \$26 furnace. Aside from this the market is featureless.

Ferro-tungsten: Quotations are nominal at 40 to 45c. per pound of contained tungsten for the domestic alloy, with the foreign quoted at 50c., duty paid, seaboard.

Ferro-silicon: A moderate activity is noted at ruling prices of \$55 to \$57, delivered. Some sellers quote \$60, delivered, as a minimum.

Ferro-chromium: Regular standard alloy, 4 to 6% carbon and 60 to 70% chromium, is obtainable as low as 10 to 11c. per pound of contained chromium from domestic producers.

An investigation of the electrothermic smelting of zinc and the condensation of zinc vapor is being undertaken at the Mississippi Valley Experiment Station of the U. S. Bureau of Mines at Rolla, Missouri, in co-operation with the Missouri School of Mines and Metallurgy. A critical study of the physics and chemistry of the condensation of zinc vapor will be made for the purpose of obtaining sufficient data to design a condenser for an electric furnace which will result in the elimination or diminution of the formation of blue powder. The investigation will be made by B. M. O'Harra, assistant metallurgist, William Kahlbaum, co-operative chemist, and Clarence W. Burkhart, fellow in electro-metallurgy, the work being under the general supervision of D. A. Lyon, chief of the metallurgical division of Bureau.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE SULLIVAN MACHINERY CO.'S MOVING PICTURE OF ROCK-DRILL PRACTICE

A feature of the machinery exhibit, in the Chicago Coliseum, in connection with the recent meeting of the Mining Congress was the four-reel moving-picture film exhibited by the Sullivan Machinery Co. The purpose of the film is to show as many phases of work with rock-drills as possible. The result is an entertaining as well as an instructive 'show' for which the Sullivan company has reason to feel proud. The accompanying illustrations give some idea of the character of the pictures. The four sections of the film deal with the following phases of rock-drill work.

1. Pictures taken at Mineville, New York, and at Hurley,

Typical Views from the Sullivan Company's Moving-Picture 'Show'

Wisconsin, showing the use of hammer- and rock-drills in shaft-sinking, heavy drifting, stoping, block-holing, etc. A feature is the shaft picture taken 1700 ft. underground, said to be the greatest depth at which a moving picture has ever been secured.

2. Stone-quarrying: Pictures taken at Westerly, Rhode Island, in the granite quarries and stone-cutting sheds, illustrate the use of heavy piston-drills mounted on tripods and quarry-bars; of plug-drills for splitting the blocks of granite; of 'steam splitting' of compressed-air drilling; and surfacing and carving tools in the granite-sheds.

3. Excavating rock on construction work: Pictures taken at Niagara Falls, Canada, on the ten-mile power-canal of the Hydro Electric Power Commission of Ontario, now almost completed. This reel shows remarkable pictures of

channelling, tripod-drilling, submarine-type drills, rotator drills, steam-shovel work, concreting, and floating-dredge excavations.

(4) Drill-steel heating and forging: Illustrates the use of oil-forges with magnetite and pyrometer-heat control, and of compressed-air drill-sharpeners for forging drill bits and shanks. Pictures were taken at Ironwood, Michigan. The picture is noteworthy for the variety of scenes shown, all of which are actually taken in the field, and not in the factory or shop.

PACIFIC COAST DIVISION OF HYATT ROLLER BEARING CO. IS ESTABLISHED IN SAN FRANCISCO

The district office of the Hyatt Roller Bearing Co., at 74 New Montgomery St., San Francisco, has become the Pacific Coast Division; and unlike the other Hyatt organizations, the 'baby division' incorporates all three fields, namely, motor, tractor, and industrial. It is under the capable management of A. W. Fisher.

Mr. Fisher decided that in order to render real Hyatt service to the many coast industries, he required the services of another Hyatt experienced man, and accordingly the home office elected to send him a man thoroughly trained in Hyatt industrial applications, through several years of close association with the big industries of the East. George L. Thom, therefore, has promptly proceeded to sell himself on California and all the Pacific Coast.

Another change in Mr. Fisher's organization was effected when Philip Overman was transferred to Minneapolis. He was succeeded by 'Chip' Nagle, who looked after the mechanical inspection and experimental engineering at one of Uncle Sam's flying-fields during the War. Mr. Nagle is in the same capacity with Hyatt. The services of the Pacific Coast Division engineers are cordially extended to all those within its territory.

NEW ROLL-CAPACITY TABLES

Anyone who has ever tried to figure roll-capacity from the complicated diagram-charts usually employed will appreciate the new and original tables of roll-capacities contained in the C. G. Buchanan Co.'s new Bulletin 13, on Type 'C' crushing-rolls. These tables are very simple and easily understood. By their use any operator can quickly determine the size, speed, and number of rolls to be used for accomplishing a given amount of work.

Among the general data also included in this new Buchanan bulletin is a brief history of the origin and first introduction of rolls. The data given on the large capacity and the comparatively small amount of power required to operate these early and imperfect machines will be of keen interest to anyone who is not thoroughly familiar with the

use or possibilities of rolls as a crushing device for medium-fine crushing. The work accomplished by the pioneers in the use of rolls renders it unnecessary to make extravagant claims for present-day roll-performance.

The limitations of rolls are also clearly shown, particularly in regard to sizes of pieces that rolls can economically handle and the reduction that can be made in a single pass.

NEW SIGNAL DEVICES FOR INDUSTRIAL PLANTS

The Klaxon Co., for years well-known maker of automobile horns, is now turning its endeavors to the manufacture of industrial and mining signals. The Western sales agency for the company's products has been secured by E. D. Bullard, 268 Market St., San Francisco. One of the devices is the Klaxon industrial horn, which is an improved

Klaxon Horn for Industrial Use

automobile horn, changed in design to fit industrial purposes. Another is a single-stroke bell. There have been great calls for these, and the Klaxon Co. has made a positive-contact single-stroke bell by which code-calls can be sent, as each contact gives but a single stroke to the bell. In order to make its horns and bells even more useful, the company has added the 'Klaxocator', an instrument by which automatically any blasts on horns or strokes of bells can be sent to as many different stations as desired. In this way executives can be called, or alarms or time-signals can be sent out from one central station and a code-call repeated in numerous places around the plant.

COMMERCIAL PARAGRAPHS

Lynch Brothers, diamond-drill contractors, have announced the removal of their offices from 624 Alaska Bdg. to 219 Pioneer Bdg., at Seattle, Washington.

E. E. Aldous has been appointed representative for the American Steel & Wire Co. in St. Paul-Minneapolis-Duluth territory. Mr. Aldous, whose headquarters will be at St. Paul, has been connected with the company for 20 years in different positions and, therefore, is well posted in the different lines handled.

Bulletin No. 234, entitled 'The Continuous Heat-Treatment of Metals with Automatic and Semi-Automatic Furnaces', is the fourth of the series, published by the W. S. Rockwell Co., dealing with fundamentals that influence the quality and cost of heated products. This bulletin illustrates practical applications of the principles outlined by the previous bulletins of this series—No. 230, 231, and 232.

J. C. Townley, formerly district manager of the Pittsburgh office of the Cement-Gun Co., sailed for Holland on October 15, where he will take up his duties as general manager of the International Cement-Gun Co. The International Cement-Gun Co. has been recently organized to handle the foreign business for the Cement-Gun Co., with the exception of Canada, Mexico, and Cuba. The address of the company is 56 Maria Plaats, Utrecht, Holland.

The Powdered Coal Engineering & Equipment Co. moved its office and manufacturing plant from Chicago to Buffalo,

New York, on November 1. The personnel of the organization has been somewhat changed, and H. B. Pruden has been elected as chairman of the board and J. W. Lansing of Buffalo has been elected president. The new board of directors of the company is as follows: J. W. Lansing, Fenton M. Parke, J. E. Finley, Harry R. Wait, J. C. Trefts, H. B. Pruden, B. W. Wistar, W. M. Faber, and Stephen T. Lockwood.

The Universal Crane Co. announces that George L. Sawyer has been appointed to represent it in the New York field in the sale of Universal cranes. His offices are at Allied Machinery Center, 141 Center St. Keen interest in the Universal crane has been shown throughout the territory due to the crane's adaptability to so many types of mountings and its great flexibility and economy in almost all material-handling fields. The big time-saving feature of this crane is its ability to be mounted on motor-trucks and trailers on which it can be moved from place to place several times as fast as other full-revolving cranes.

The primary function of a reflecting device or globe is to direct, diffuse, or modify the light given off by an incandescent lamp in such a manner as to make it more useful. Light from a bare incandescent lamp is given off approximately equally in all directions; therefore, to direct this light to certain areas some accessory is necessary. To serve this purpose, many types of reflectors find application, depending upon the particular use to which the lamp is put. An interesting discussion of the principles involved in obtaining efficient lighting by means of reflectors may be found in Bulletin LD-123, recently issued by the Edison Lamp Works of the General Electric Company.

The Stamp Electric Hoist Co., established in San Francisco during the early part of this year, is manufacturing electric hoists in lifting-capacities of from 500 lb. to 15,000 lb., the types ranging from the stationary hoist to the electric-driven cab-operated mono-rail system. A feature is their simplicity and accessibility. Inquiries for hoists should contain as nearly as possible the following information: (1) Kind of current. If alternating, state voltage, phase, and cycles. If direct, state voltage. (2) Capacity. State about what usual loads will be handled; also the heaviest load. (3) Type. Suspension, plain, or geared trolley, motor-driven trolley, floor, or cab-controlled. (4) Height of lift required. (5) Speed of lift required. (6) Kind of service to be performed. (7) Single or variable speed-control. (8) Outdoor or indoor service. (9) If trolley-hoist, state size of I-beam on which trolley is run.

'Dry-Vacuum Pumps' is the title of a recent bulletin published by the Chicago Pneumatic Tool Co. It presents a line of dry-vacuum pumps in which several new features of design are incorporated. In their design and construction the purpose throughout has been to produce pumps for duty where unquestionable dependability and sustained operating economy under exacting service conditions are paramount considerations. All that the finest materials and the most modern engineering facilities and practice can contribute toward the construction of a vacuum pump will be found in these machines. Through the elimination of inlet valves, as well as through the use of the efficient 'Simplate' discharge valve, clearance has been minimized; hence the volumetric efficiency has been increased to such an extent that a vacuum within one-half inch of the barometer may be obtained. A further advantage of the new design lies in its simplicity, with consequent ease of operation, long life, and small number of parts to get out of adjustment. For service where only high vacua (22 in. of mercury up) are desired, pumps of the new design, without inlet valves, are recommended for the highest operating efficiency. For installations where low as well as high vacua are required, Chicago Pneumatic dry-vacuum pumps are equipped with 'Simplate' inlet valves.

T. A. RICKARD. . . . Editor

IN our issue of August 20 we discussed the labor troubles at Grass Valley and the proposed arbitration. The latter was not put into effect, for reasons we suggested at that time, but on November 12 an agreement between the operators and the mine-workers was signed whereby \$4.25 is paid to machine-men and \$3.78 to shovelers, with extra pay for special work and for over-time.

REDUCTION in freight-rates, recently announced by the Southern Pacific Company and by other important transportation systems, will be welcomed as a significant move toward the re-establishment of normal conditions. A large item of the cost of delivered mining equipment, which is often exceedingly heavy, is the freight-charge. The reduction in rates for transportation will serve to encourage an early resumption of work in many mines, and will act as an incentive to increased activity in others.

COPPER statistics continue to improve. The sales of refined metal in October as compiled by the American Bureau of Metal Statistics show an aggregate of 140 million pounds, as against 97 millions in September, and an average of 75 millions in July and August. The October sales contrast cheerfully with a combined American output and import total of about 50 million pounds. A premature statement that the Inspiration Consolidated Copper Company was about to resume operations has been denied, but similar rumors may be expected henceforward, and it may not be long before an actual resumption of our big mines becomes a fact.

AMERICA can compete successfully with Germany for the trade in electrical machinery for South America. On the other hand, Germany seems determined to win back her position as a supplier of cheap ironwork. Bids were submitted recently to the Ministry of Public Works in Buenos Aires for a highway bridge over the Rio Segundo, in the Province of Córdoba. The six lowest bids were from Germany, then one from Belgium, then three more from Germany, and lastly one from Belgium. No American or British bids were made, a consular report stating that the lowest price that any American firm was prepared to mention would have been over three times the lowest German bid. On the other hand, the

recent acceptance of the bid of the Westinghouse Electric International Company, for the machinery needed for the electrification of the Chilean State railway between Valparaiso and Santiago, draws attention to the fact that a strong German combination was underbid to the tune of about \$4,000,000. Thus it seems that American-made goods that contain a considerable amount of copper, in spite of high labor cost, are maintaining a hold on the markets of the world.

ULTIMATE revival of gold mining in Victoria, Australia, as well as in other States of the Commonwealth, is predicted by Mr. E. C. Dyason, the president of the Victoria Chamber of Mines. Australian gold mining, at the present time, is likened by him to "a patient that was being kept alive by the precarious oxygen of the gold premium"; the cessation of operations in Victoria, he affirms, will be due to economic and not to geologic causes, for few of the goldfields of that State have been exhausted of their reserves of 'ore'. This condition is similar to that which exists in many other parts of the world. The exploitation of low-grade copper ore would have been impossible but for improvements in metallurgical practice and the adoption of large-scale methods of mining and treatment. The gold-mining industry is passing through a similar phase of existence.

INVESTIGATIONS that should prove of value to the mining industry are being conducted at the Forest Products Laboratory at Madison, Wisconsin, on the preservation of timber used underground. A study of the problem has indicated that much unnecessary expense may be avoided by proper storage. Lumber yards should be on well-drained ground, free from debris and weeds. A proper foundation for a lumber pile is essential; adequate ventilation should be ensured by proper stacking. Investigations have been made to determine the value of treatment with various preservatives, to demonstrate the difference between harmless molds and wood-destroying fungi, and to estimate the worth of charring in the preservation of wood. A brief paper on the subject, by Mr. R. R. Hornor, of the U. S. Bureau of Mines, and Mr. G. M. Hunt, of the Forest Products Laboratory, has been prepared. In this the authors discuss the vitiation of air in mines by decaying timbers, the hazard of fire, and the extension of the life of timber by preliminary peeling.

Coal-tar creosote and zinc chloride are quoted as standard preservatives, application by pressure being recommended. Examples are given of results obtained by preliminary treatment. In one case, where untreated timber lasted but two years, treated timbers have been in service for 14 years and are still in sound condition; the treatment added but 10 to 15% to the cost, and increased the life of the wood by 600%. Treated mine-timber can be expected to withstand decay for from 12 to 20 years. The subject has been neglected by those in charge of many small properties. The work being done by the Forest Products Laboratory officials, in conjunction with Bureau of Mines engineers, is for the benefit of the mining industry, and operators should avail themselves of the results.

RESULTS and achievement can be judged only after due consideration has been paid to the question of time taken to carry out the work. Mr. W. F. Dietrich, who is Associate Professor of Mining at Leland Stanford University, contributes in this issue an interesting and educative article on time studies in metallurgical analysis, which should stimulate thought and should encourage imitative action elsewhere. It is pointed out that during the time spent in American universities, and we believe in those of many other countries also, the student is not encouraged to appreciate the value of a high standard of efficiency in personal action, or to avoid a wastage of time when he is supposedly at work. It has been estimated that the time required by different students for a single assignment may vary from half an hour to eight hours. Judgment as to merit is based on quality and quantity of work submitted, and no regard is paid to the factor of time. Thus, as Mr. Dietrich points out, many graduates enter industry handicapped by the circumstance that they have no idea of the proper connection between the performance of a task and the time taken to perform it. Thoroughness and accuracy are essential, of course; but results have shown that both are helped rather than hindered by an appreciation of the need for economy of movement and the systematization of action in individual effort.

IN this issue Mr. Albion S. Howe contributes to the general discussion of the proposed new mining law, emphasizing the difficulty that is experienced by prospectors and others who wish to know whether or not mineral land is open for location. If anyone is willing to prospect, he asks, why demand a discovery? The Central and South Eureka mines at Sutter Creek, California, for example, have a surface covering of gravel, of from 50 to 150 feet; ore in place could not have been discovered at the surface. The Central was located as a lode claim, and the South Eureka was patented as agricultural land, good for fruit and grain on the surface and for the exploitation of the Mother Lode gold deposits underneath. Other examples might be cited. Mr. Howe's view is supported by nine prospectors, whose letter on the same subject follows, and who register an emphatic protest against the proposed

law, stating that they consider that its passage would result in the stoppage of prospecting and the extinction of the prospector. Incidentally we note that the committee on mining of the Commercial Club of Salt Lake City opposes the bill; this may be accepted as indicating the prevailing sentiment in Utah. Our Mr. Allen comments on the solubility of gold in mercury and the wetting of a sulphide by oil. Mr. A. W. Fahrenwald discusses several interesting points that were brought out in a recent article in our columns by Mr. Frederick G. Moses. He maintains that, in modern froth-flotation operations, all the particles of ore in a pulp are wetted with water before the oil is added; and that, when the oil is added, the water on the surface of the mineral particles is displaced by the oil, whereas other particles remain wetted with water. Mr. Fernando Benitez writes from Chile on the status of the natural nitrate industry. Mr. Alfred T. Fry writes from distant Tasmania and describes a simple scheme for comparing the mechanical efficiency of flotation-machine impellers and for obtaining other useful information.

The Washington Conference

The third anniversary of the Armistice was celebrated in diverse ways, suggesting the mental attitude of divers persons. Some saw in the day merely the date on which the War ended, so they assembled at dinner parties and dances; others accepted the President's proclamation as the fixing of a holiday, so they went to football matches; others used the opportunity to play golf. To none of these did the day mean anything in particular. To the more thoughtful the public burial of the unknown soldier afforded a chance for a local ceremonial at which the thousands of the unreturning dead were duly honored. At Washington itself the President and his administration represented the American people worthily by paying respectful tribute to the typical hero of the War; and the President himself, standing in a soldiers' cemetery, confessed the failure of a civilization that leaves its problems to the arbitrament of wholesale murder, and voiced the hope that the awakened conscience of the world would make itself heard in the councils of the nations. The ceremony on Friday was a fitting prelude to the opening of the Conference on Saturday. There again the President spoke for our people when he said that they "want less of armament and none of war". He spoke for "a war-weary world, struggling for restoration, hungering and thirsting for better relationship; crying for relief and craving assurance of lasting peace". His speech of welcome to the delegates was followed immediately by a frank proposal, made through the Secretary of State, for a temporary cessation of naval construction on the part of the three principal maritime powers. The proposal was made in a manner that augurs well for beneficent results. To Mr. Harding and his associates has been given an extraordinary opportunity to perform a service to humanity that will make them honored for all time; to the United States is accorded an oppor-

tunity to achieve "that nobler thing which no nation can do alone". It is a great occasion, and the representatives of our republic have risen to it finely. Even the meaner part of the daily press has felt the urge of public opinion and is giving serious consideration to the Conference. Our hopes and prayers are with the statesmen at Washington; the whole world stands on the tiptoe of anxious expectation. The confidence of the public, however, is disciplined by the remembrance of the bitter disillusionment that followed the Treaty of Paris. The contrast between the brave promises and the ignoble performance of that conference is still in our minds; and, if we hope for better results now, it is largely because we believe that the atmosphere of public opinion is more favorable to a fruitful outcome; the peoples of the earth are sadder and wiser, they are better informed and less visionary than they were three years ago; humanity at large is sick and tired of war and the fruits of war; they know these fruits to be bitter to the taste, even in the mouth of the victor; they look to their leaders to make an end of a hateful system and intend to hold them to account if they fail to accomplish the salutary purpose for which they have been sent to Washington at this time. They must disarm their minds of the prejudices that wrecked the Paris conference, and we, of the public, must do likewise, if anything lastingly useful is to be accomplished. For the American people, as for others, it is necessary to consider how much of independence it shall forego in order to recognize the interdependence of all the peoples. As the individual surrendered some of his freedom for the sake of community life, so each nation must yield some of its sovereignty in order that the life of the world as a whole may be sustained and bettered. If conscience and sentiment fail in arousing general sympathy with the peacemakers, it seems likely that the pocket-nerve may awaken the self-interest of the citizen in every country. As Lord Morley has said, the tax-collector is the true school-master; he has been teaching us how appalling is the cost of war, and how great is the burden it is imposing both upon the wealth and the manhood of all the nations. Armament and other preparations for war mean the support of masses of non-productive men by those who are engaged in productive industry; it is a tax that humanity must refuse to pay, for economic reasons alone, wholly apart from the nobler sentiment that recoils from the spectacle of the scientific killing of the flower of the race. The cost of a battleship represents a sum equal to the endowment of a university; the battleship 'California' cost more than Stanford university. At this moment millions are starving and the channels of industry are clogged by the ruins of war; the structure of human society is in danger of disintegration and a few wrong-headed men continue to arouse the snarling instincts that man inherited from the jungle. It is high time to call a halt, to take stock of ourselves as inhabitants of an unhappy planet, to prevent the suicide of our civilization, and to resolve to do our very utmost to promote the consummation of "that far-off divine event to which the whole creation moves".

The Missouri School of Mines

Most of our readers will be surprised to learn that the State of Missouri has a School of Mines old enough to be able to celebrate its semicentenary; yet such is the case, and on November 5 this fiftieth anniversary was celebrated in proper style. The School constitutes a part of the University of Missouri, but it is established at Rolla, whereas the University itself is at Columbia. The little agricultural settlement of Rolla is situated in the Ozark region and is well placed in respect of the mining districts of the State. The buildings and equipment of the School are well adapted to their essential purpose; the faculty has won the respect and regard of both past and present students; the institution has achieved a distinct place among the educational establishments of the country. At the present time 586 students are in attendance, but, of these, 162 are non-collegiate men who are receiving a vocational training in topographic surveying and highway work—ex-soldiers to whom a new start in life is being given. The graduating class numbers 160. A School of Mines such as this is known by its graduates, as a tree by its fruit. The 'M. S. M.' has sent forth many good men, among whom we venture to mention Messrs. D. C. Jackling, John W. Paek, W. Rowland Cox, Preston K. Horner, Herbert R. Hanley, and W. W. Wishon among those whom we happen to know as successful mining engineers and metallurgists. Mr. Jackling's pre-eminence is readily acknowledged by his fellow alumni, and it is fair to say that a mining school that trained a boy to become such a captain of industry has fully justified its existence. The semicentenary was celebrated by a football match, an alumni banquet, a meeting of the St. Louis section of the Institute, the organization of an Alumni Association, and an address by a representative of the mining industry. The event brought men from distant parts; for example, Mr. J. K. Walsh, of the class of '17, came from Cerro de Pasco. The various speakers expressed affection for their Alma Mater by happy allusions, and recorded their goodwill toward members of the faculty, among whom Mr. George R. Dean, Professor of Mathematics, was specially honored; indeed he seems to play the part at Rolla that Van Amringe does in the traditions of the Columbia School of Mines. Repeated references were made to the pleasant relations that have been maintained between the School and the townspeople, and several local citizens received friendly mention on the part of old students. Two of the former Directors of the School, Messrs. L. E. Young and A. L. McRae, were present and spoke felicitously. The present Director, Mr. Charles H. Fulton, a Columbia graduate, holds the respect of faculty and students alike; he is an earnest man and is imbued with broad ideas, so that the future of the School is in safe hands. Mr. Arthur D. Terrell was toastmaster at the banquet and was chosen as president of the Alumni Association, which was organized at the close of the dinner. The starting of this fraternal union was the most important event of the celebration, for it will serve to sustain the personal interest

of the widely scattered alumni in their Alma Mater; it will create a body that can speak for the best interests of the School; and it will serve to crystallize the traditions upon which the higher spirit of such an institution lives. The Missouri School of Mines has made good; we wish it continued success and prosperity.

Mechanical Shoveling Underground

In this issue we publish a timely and informative article on the 'Use of Scrapers Underground'. For this we are indebted to Mr. Lucien Eaton, mine superintendent for the Cleveland-Cliffs Iron Company in the Ishpeming district of Michigan. Incidentally, we compliment Mr. Eaton on the evident care taken in the preparation of this article, which, in many respects, is a model of technical writing. The subject is one that is engaging the attention of most managers of mines, as is indicated by the replies received in response to our recent interrogatory on conditions in the industry. One of the questions in this catechism asked "What class of machinery is least satisfactory in the performance of its function?" The manager of a gold mine answered succinctly, if somewhat whimsically, "The shovel". He had in mind the familiar No. 2 with a hickory handle and a steel blade. In mines where some system of caving or shrinkage-stoping is not used, it is probable that, until a few years ago, much more than half of the labor underground was expended in getting ore from the face, where it was broken, into a car on a haulage-level, or into a chute from which it might be loaded into such a car readily. This is the work known as 'mucking'. The man who does it may have a small car, or a bucket on a truck, which he loads and pushes to a chute or to a larger car, and dumps it; a wheelbarrow may be substituted for the car, in which event he does not need to lift the ore so high. If he is working in a drift on the main level he probably loads a larger car and must lift the ore still higher. But under any and all circumstances he works with a shovel; the shovel is to him as the trowel is to the mason, or the needle to the tailor. There is an art about using a shovel; a good shoveler can load twice as many cars as a poor one, and tire himself not nearly so much. Ore is hard and heavy; large pieces are mixed with small; the filling of the shovel is difficult; the raising of it, loaded, is a strain; and, if the ore has to be thrown or carried, more arduous effort must be expended. The toil of a shoveler who makes a 'good showing' for his shift's work is heartbreaking, as only those who have done it know. But, disregarding the human element, under most circumstances shoveling by hand is deplorably inefficient from the cold-blooded standpoint of dollars and cents. If the shoveler fail to do a reasonable day's work the net efficiency is diminished in proportion. It seems astonishing that effort was not directed 30 years ago toward development of devices for applying mechanical power to the work of loading ore underground. Coal-mine operators were the first to make use of mechanical loaders, but in the last

decade rapid progress has been made in developing machines to meet the requirements of metal mines, and in introducing them underground. This may be accounted for largely by the prevailing high wages, by a growing tendency of employees to take things easy, and, during the War, by a shortage of men. The results of the first two were reflected in the cost-sheets; of the last, in the production record. The only remedy was the development of devices and the utilization of mechanical power that would enable a given number of men to move more ore than they had been moving, and with less physical labor.

There are manufactured today several machines costing from \$3000 to \$10,000 that are satisfactorily loading broken rock in large adits or tunnels. Although not perfect, several of these machines have a large capacity; they are reasonably rugged and mechanically efficient; but they are bulky and costly and are accordingly most suitable for work in large headings and on long jobs. In general there are two types of machine; those of the first type operate on the principle of a steam-shovel; they consist of a dipper that digs into the ore, obtains its load, swings around, and dumps directly into a car. Those of the second type may be likened to a dredge, in that the bucket or buckets travel on an endless belt or chain and discharge onto a conveyor that in turn carries the rock to the car. Numerous ingenious machines have been built embodying these broad principles. For the ordinary work in most metal mines, however, these machines are too costly, too cumbersome to transfer from place to place, and too dependent upon the attention of an expert mechanic. The impracticability of using such a machine in the average stope is obvious, although an exception must be made of the mining of horizontal bedded deposits having large area. Under such circumstances the advantages of a mechanical shoveler may be sufficient to warrant its use.

As an alternative to the complicated mechanical loader, the steel scraper operated by means of wire-rope lines actuated by a small air- or electric hoist has come into general use during the past five years. Mr. Eaton's article describes the various types of scrapers; it discusses the principles of their design and the methods of using them, the field for which they are most suitable, and their limitations. He remarks that the technique of operation has not been perfected, by any means, and invites an exchange of views on the subject. The ideal 'shoveler' is a fool-proof machine, of reasonable price, that will handle both coarse and fine material; that is light enough to be moved about from one drift to another or from one part of a stope to another; that will operate efficiently in an ordinary drift; and that, in addition, will do the work rapidly. This is a large order; it is improbable that any one machine will be built to fulfil all these requirements, but it is not improbable that, before many years, the inefficient drudgery of shoveling by hand will join the arts of single-jacking, and of sharpening drill-steel with a two-pound hammer on the old anvil, as relics of a forgotten past.

DISCUSSION

Mining Law Revision

The Editor:

Sir—In the discussion of the proposed mining law revision, I agree entirely with Robert B. Brinsmade in his article in your issue of October 8. The Government should retain ownership of its valuable minerals for the use of future generations. There is no better mining law than that of Mexico, where the surface rights are separate from the mineral rights and where any prospector can easily learn whether or not a prospect is open for location.

In your paper, not long ago, you were inviting discussion as to why there are not more prospectors, and why they do not prospect and find undeveloped ore deposits. The principal reason is because there is so much patented land that is not open to location. After a few years the stakes or monuments disappear, and no one can tell, without a survey, whether or not he can enter and make a location that will hold. Much mineral land has been taken and patented as agricultural land, and such applications for patent are continually before the General Land Office. When land is once patented before mineral discovery, there is not one chance in a thousand of anyone attempting to develop a mine therein. The rancher will not mine, nor will the miner farm. Much mineral land can be used for agricultural purposes, and when such is the case, why not allow development of both the underground and the surface resources? Would it not be for the public welfare? If so, the welfare of the public should come first. Mining laws should not be framed wholly in the interest of the corporations, nor of the prospector; nor should mining development be prevented by grazing and agricultural interests. Idle patented claims should be so heavily taxed that they will eventually revert to the State.

Under the proposed new mining law, one discovery is sufficient to support the holding and patenting of 160 acres of contiguous claims. Also, all claims must be patented within seven years after location, except when a special extension is secured. These provisions are certainly against the interests of the people and of the prospectors. It is to the public interest that all resources be developed and that mineral land be worked. Patenting does not encourage such development. Most patented claims lie idle and pay only nominal taxes, whereas the producing mine has to stand the maximum taxation that can be given by the county assessors. All over the West are prospects and mines that have been shut-down for years, and that would now be working

if they were held under leasehold and not under patent. Furthermore, most mining companies hold mining claims that they will never work. The land is patented, and none but the company can enter to prospect or to mine. The average mine-workings can be covered by one or two mining claims. Under the leasehold system, whenever an individual or a company takes up more land than it can develop, the annual tax on such idle lands tends to cause a release to the Government. Others then may have a chance to locate and to develop.

Why the proposed provision of the new law that mining claims must coincide with the lines of the public survey? It may make it easier for mapping purposes in the Surveyor General's office, but it will certainly be a handicap for the prospector and the locator.

If the gentlemen who framed these proposed laws had ever hunted for section-corners in remote places, perhaps this proposed location of claims along section lines would not have been advocated. I once searched all day for a section-corner in a Nevada town, examining rock-pile after rock-pile; the corner was finally found under the board-floor of a tent. In many sections, one could not find section-corners without a survey, and perhaps not then. Much of that surveying work was done by government contract, and in some cases the corners never were placed; just paper locations were made.

In San Diego county is some good mineral land. Last year, according to the U. S. Mines Report, the gold production was \$71.11. Evidently, not one mine, and perhaps not a prospector worked last year in the whole county. And why? The best mineral land there is plastered over with old Mexican land-grants; and, outside of those areas, the proved mines have been patented. There is a dense growth of chaparral and manzanita along the best-known mineral belt, so dense that in many places a dog cannot pass through. A new-comer could not find a section-corner, nor a land-grant boundary, in a month. Who is going to pay for surveys to determine where he can or cannot prospect? If all mineral rights had been reserved by the Government and the land leased for mining, there would be mines working in San Diego today. Do we not all agree that the prospector should be encouraged? As to the new requirement for surveys, why put the prospector to that expense? New Zealand mine-laws have, or had, such a requirement before leasehold land could be held. The result was that no poor man could locate and hold Government mineral land.

The proposed abolishment of extra-lateral rights is a good thing for the mining industry and does the prospector no harm. How many prospectors ever sink deep

enough to go beyond their side-lines? A mining company or a locator now has to take up claims alongside the discovery claims to provide for the "dips, spurs, and angles", so as to try to prevent extra-lateral litigation. Under the proposed new laws, the locator can take up a claim or two alongside to provide for the dip of his discovery-vein outside the side-lines. Later on, should he find that he will not require such claims, he can let them revert to the Government.

If mineral patents are not granted, then there should be no requirement as to mineral discovery. Let the locator work and prospect, and if he employs men and buys materials, it helps the community near him. Most ventures of such a character will be losing ones, but in any case the community will be the gainer. When a locator or his successor develops a producing mine, the county and the State also profit.

Certainly no person should be allowed to hold and to patent 160 acres of lode claims on one mineral discovery. I have sampled many such alleged 'mineral discoveries', after patent had been applied for, or granted, and the most of such discoveries would not sample 50c. per ton. On the other hand, many agricultural patents have been granted where there were indications that mines might have been developed by proper underground development.

The holding of claims for five years without discovery, provided the claims are worked, is a good law, as is also the limited-time extension after payment of the \$50 per acre. Such money will not be paid unless there is a good chance; anyone who will pay \$50 per acre for the privilege of prospecting and developing should be allowed to proceed.

In looking over the proposed laws, it would seem that the committee has considered the mine-law changes more from the viewpoint of the mine operator, rather than from that of the prospector or that of the general public. The mining laws should be drafted to aid the whole mining industry, and not solely for mine-owners and prospectors. Every individual in a mining district, or in a mining State, is directly interested, and therefore we should all make an effort to get the best mining code, one that will encourage and not retard the development of our mineral resources.

ALBION S. HOWE.

Sutter Creek, California, October 29.

The Editor:

Sir—We would like to register a protest against the proposed new mining law.

To locate and follow section-lines would be impossible here because in most places no section-corners can be found, and, while the valleys have mostly been surveyed, many of the mountain ranges where the ore is found are still unsurveyed.

The doubling of the size of mining claims would work a great hardship on prospectors as it would compel them to take up much more ground that would be of no value to them, and would compel them to do annually twice the

amount of assessment work. Requiring them to pay \$5 per acre instead of doing the assessment work would knock them out completely, because they haven't got the money.

Demanding \$50 per acre from prospectors after five years simply means that they would all lose their claims, because most prospectors work until they haven't got 50c. let alone \$50 per acre to pay for the ground. Of course, we know that this new law would not apply to most cases.

Fixing a time when patent must be applied for would also work a great hardship on many prospectors. In our own cases Sam Cocroft, after working six years, now has enough ore to make one small shipment so he can pay for his grub and keep on mining, but not enough to pay for patenting his mines. Before this he has had to take outside work to get a grubstake. R. A. Dean has worked 14 years and was compelled to work out every year for his grubstake and even now has not enough ore to ship.

Prospectors do not take up a claim unless there is an outcrop or some ore in sight, so they do not care to have a law giving them five years to find the ore.

Then we must consider well that our present mining laws are buttressed by many decisions from all our courts, including the highest, so that we now know quite positively just where we are. New court decisions would be required to clarify the new law and to make us know its meaning. We have read that it took 20 years to get court decisions so that the Sherman anti-trust law could be enforced. It would take at least as long, if not longer, to get this proposed new mining law adjudicated, and during all that time we would be working more or less in the dark.

The apex law might be improved by some changes but otherwise neither we nor any of the other prospectors and mine-owners here desire or wish any changes in the present law. In fact, we feel that the proposed new law would mean the total stoppage of all prospecting, so far as prospectors without capital are concerned, and that the present class of prospectors, who have done so much to develop our mining country in the past, would become extinct.

Wetting and Amalgamation

The Editor:

Sir—S. H. Dolbear, in his notes that were published in the issue of November 12, is, I think, correct in assuming that the examiner of the Patent Office, who proclaimed an analogy between the amalgamation of gold by mercury and the wetting of a sulphide by oil, was mistaken in his ideas on the subject. The fact that gold is soluble in mercury has been known definitely for some

time. Recently, S. A. Braley and R. F. Schneider*, after confirmatory tests, came to the conclusion that, in the gold-mercury series, there are three eutectics, and three compounds— Au_2Hg , Au_2Hg_5 , and AuHg_4 ; the last-mentioned compound was found to decompose into Au_2Hg_5 and mercury at its melting point.

Agitation in Flotation

The Editor:

Sir—I am much interested in the article on 'Agitation in Flotation', by Frederick G. Moses in your issue of October 1, for it is a question of considerable importance, as Mr. Moses has intimated. Knowing him personally, I understand his keen interest in the discussion of flotation problems. With the hope of adding further light to a few of the points in this paper, I am undertaking to discuss some of them.

In connection with the question of the condition of the oil in a flotation pulp, many times the subject of considerable speculation, he states: "Thus, if the oils were properly emulsified, the mixture should remain in an exceedingly fine state of division indefinitely, or for a long period. But the oils, to be effective, must coat the sulphides and bubbles. If the oil is available for coating the bubbles, and sulphides, it cannot be thoroughly incorporated in the pulp; it should exist in a comparatively unstable condition, in order that it may be easily available".

In the first place, in spite of the work done by Bancroft, we are not certain as to the exact condition of most flotation oils in water. It is certain that, if an oil is effective, it must coat the mineral or adsorb on its surface; but there is no experimental evidence to support the statement "if oil is available for coating bubbles or sulphides, it cannot be thoroughly incorporated with the pulp", or for the statement that "it should exist in comparatively unstable condition in order that it may be easily available".

Soap unquestionably promotes emulsification of the oil, but it also does something else that I believe is more significant than this. Very small quantities of certain soaps lower the surface-tension of water to such an extent that oils will not spread on its surface. This was pointed out by me in a recent paper.† If flotation oil cannot spread on the free surface of water it certainly cannot be of use as a flotation agent. Such an oil might have been suitable for use in the old bulk-oil flotation process. If an oil does not possess the property of lowering the surface-tension of water, it would have no tendency to go into the water-air interface provided by the bubble, and oiled mineral particles would not be caught by the bubble. Bubbles as such have no attraction for mineral particles. Their function in flotation is to give

added surface into which oiled mineral particles may gather, and to act as carriers of this surface to the free pulp-air surface where the minerals concentrate. This soap will tend to make pine-oils behave in their spreading properties on water as do the paraffin oils on clean water. Instead of forming a film, the oil will, on a soapy water, form as a lenticular globule.

The function of chemicals in a flotation pulp is a matter of speculation. It can, however, be determined that certain chemicals increase or decrease the amount of oil adsorbed on a unit of mineral surface; this is, no doubt, a result of an alteration of the interfacial tensions, solid-oil, solid-water, and water-oil.

If, for example, sulphuric acid affects the stability of an emulsion it cannot be shown experimentally, or it has not been done, that it is this effect that is doing good in flotation.

Mr. Moses states: "On the assumption that emulsification may be carried too far, it is possible to explain why $\frac{1}{4}$ lb. of oil added to four different places in a series of cells will be more effective than $1\frac{1}{2}$ lb. of the same oil added to the head of the cell". I would offer the following explanation for this well-known and advantageous method of adding the oil. In the paper it was pointed out that all minerals, including gangue minerals, adsorb oil when agitated with a mixture of oil in water. It is a question of degree only. The sulphides adsorb very much more oil than gangue minerals, such as siderite and quartz; this is particularly true of emulsions of lower concentrations of oil; for the higher concentrations the gangue minerals adsorb comparatively more oil. Incidentally, this explains why the addition of excessive quantities of oil causes the flotation of much gangue, and it points to one way in which much of the $1\frac{1}{2}$ lb. of oil, if added in one batch to the first of a series of cells, would be inefficiently used. Another way in which most of the oil is used ineffectively in this kind of practice is in the large quantity frothed in the first cell. The surface concentration of the oil on the bubbles is high; and, because of the low surface-tension, many more bubbles are formed in the first cell than in any succeeding one.

Mr. Moses in enumerating the important functions of air, states that "it is necessary, in order to increase surface-tension or air-water interface, so that the froth may float". Just what the increase in surface-tension has to do with the floating of the froth is not clear. It is also not clear what the air-water interface has to do with the floating of the froth, although the introduction of air-bubbles undoubtedly increases the air-water interface.

Farther on in the paper it is stated that "a sulphide will not float readily if wetted by water. It is the air that displaces the water and prevents it from wetting the sulphide. Air or some other gas must be present in the water to prevent it from wetting the sulphide". The first sentence is true enough, but it is not my conception of flotation that "it is the air that displaces the water and prevents it from wetting the sulphide".

In the skin-flotation process it is probably true that the particles resting on the surface of the liquid are sur-

*Jour. Amer. Chem. Soc., April 1921.

†'Surface Energy and Adsorption in Flotation', 'M. & S. P.', Aug. 13, 1921.

rounded with a film of air, but it is certain that in modern froth flotation at the beginning, all the ore particles in a pulp, both gangue and mineral, are wetted with water. When oil is added and mixed, the water on the surface of certain mineral (sulphide) particles is displaced by the oil, whereas others remain wetted with water. The particles whose surfaces have been wetted by oil are thus enveloped with a substance that is eager to lower the surface-tension existing at the pulp-air (bubble) surface, and it will thus be drawn into the interface all the time, being completely covered with a film of oil, which film it retains until subsequent metallurgical treatment, such as roasting at the smelter, destroys the film.

Chilean Nitrate and Its Competitors

The Editor:

Sir—As the able and comprehensive editorial on 'The Domestic and Foreign Supply of Nitrate' (which I translated for the 'Boletín de la Sociedad Nacional de Minería', of Santiago, and discussed therein) seems to have aroused a considerable amount of attention, I trust that the information that follows will be of interest to your readers.

It is true that the price of nitrate is fixed in Chile by the Asociación de Productores, but lately the London 'pool' has exercised its influence to prevent a reduction. The quotation of 18 shillings per quintal reached in March 1920 was undoubtedly too high; as the demand slackened in response to causes that will be analyzed later, the price also dropped; in April of next year farmers will be able to obtain Chilean nitrate for about half that price. Mr. Mason's remarks call for comment. Crookes had some ground for his pessimism, because of the wasteful methods of beneficiation then, as well as now, in practice in Chile. How great was the influence that the storage of nitrate in Germany previous to the War had in making production of Chilean nitrate reach the enormous figure of 2,500,000 tons in 1913 will be difficult to ascertain; in spite of the great war demand, the output of refined nitrate only reached 3,000,000 tons during 1916 and 1918. The amount of caliche treated to date does not reach one-fifth of the total that is susceptible of exploitation. What amount can be treated by more economical exploitation and beneficiation would be difficult to estimate. The grade of caliche has decreased considerably. Caliche with 20% or more of nitrate is considered high-grade; 17%, average; and 12%, low-grade. The ability to extract the nitrate from what is now considered as low-grade caliche has resulted from economies introduced, not because of the discovery of a revolutionary process of treatment.

The development of the different nitrate-producing industries has been as follows:*

CHILEAN NITRATE. During the first 28 years following the War of the Pacific, and the acquisition by Chile of the Provinces of Tarapacá and Antofagasta, the production of nitrate increased at an almost uniform rate of 65,000 metric tons per annum. This represents an increase in output of from 225,000 tons (1880) to over 2 million tons (1908). From 1908 to 1913 the rate of increase in production rose to 186,000 tons per annum. At the beginning of the War there was a decrease (1914-1915), and from 1915 to 1918 a great increase, which in 1918 resulted in a total output of 3 million tons. The War also caused the loss of the Austro-German market (900,000 tons per annum), which has been partly offset by increased exports to Spain, to the United States, to Japan, and to various other countries, which together amounts to 850,000 tons over and above the pre-war figures. During 1919 the production fell to about one-half that of the previous year, or 1,700,000 tons. There was a recovery last year, production again going up to 2½ million tons, the exceptional price of 18 shillings per quintal being recorded in spite of the heavy stocks that had been accumulated (2½ million tons), as compared with the normal stocks of pre-war years (1,700,000 tons). Today the industry is practically at a standstill: several causes are contributory, the main ones being: (1) The high price of nitrate, 14 to 17 shillings per quintal, f.o.b. Chilean ports. (2) The depressed currency of European countries, and especially of Germany and Austria, which prevents them from buying nitrate from Chile. (3) The enormous development of the synthetic industry during the War, as well as the greater output of ammonium sulphate—a by-product of the coke, gas, and iron industries. (4) The fall in the value of agricultural products, which does not permit farmers to buy an expensive fertilizer.

PRODUCTION OF FERTILIZERS BY COUNTRIES. In 1913 Germany produced 550,000 tons of sulphate of ammonium. Today the amount is at the rate of about 300,000 tons per year as a result of the industrial upheaval caused by the War, and the loss of some of her coalfields. The future production of this fertilizer depends on industrial recovery. The growth of the synthetic-ammonia industry in Germany can be judged by the following figures:

Year	Approximate tons, in terms of sulphate of ammonium
1913-1914	35,000
1914-1915	150,000
1915-1916	300,000
1916-1917	540,000
1917-1918	840,000
1918-1919	500,000
1919-1920	500,000
1920-1921	700,000

It is said that today Germany is in a position to produce 140,000 tons of synthetic nitrogen (700,000 tons of sulphate); these figures may be increased eventually to 240,000 and 1,200,000 tons, respectively. The present production of cyanamid in Germany has been estimated variously at between 375,000 and 500,000 tons per year, which represents between 75,000 tons and 100,000 tons of nitrogen. The maximum productive capacity of Ger-

*Taken mainly from a communication by A. Bertrand to the Asociación de Productores.

many is thought to be about 600,000 tons of cyanamid per annum.

The production of sulphate of ammonium from coal rose in the United States from 150,000 tons per year in 1913 to 500,000 tons in 1920. With regard to synthetic-nitrogen products, the only producing plant is situated on the Canadian side of Niagara, and belongs to the American Cyanamid Co.; it is capable of producing 60,000 tons of 20% cyanamid. What has befallen the two government plants, at Sheffield and Muscle Shoals, is too well known to need comment.

The production of ammonium sulphate in Great Britain, which was 443,000 tons per annum before the War, rose to 159,000 tons in 1917. Last year it fell to 375,000 tons on account of strikes and other causes. The government plant at Billingham, for the production of synthetic ammonia by the Haber process, was not finished at the time of the Armistice. It has been taken over since by the firm of Brunner, Mond & Co., which formed a syndicate with a capital of £5,000,000 to acquire and finish the plant. Another company, called the Atmospheric Nitrogen & Ammonia Products, Ltd., was formed in 1920 with a capital of £2,500,000 to exploit the patents covering a process at present being tried in France.

The production of ammonium sulphate derived from coal in France is 45,000 tons, as compared with 75,000 tons made before the War; the destruction of the northern regions of France by the Germans is responsible for this decrease. A company with a capital of 12,500,000 francs has been formed in France to exploit the Haber process, but nothing has been done. The Claude process, which effects the production of synthetic ammonia under a pressure of 1000 atmospheres, is being worked on a semi-industrial scale and is said to have given satisfactory results. The production of cyanamid by the Government has proved a failure in France, and the 7 *usines* that were constructed during the War at a cost of 400,000,000 fr. for the fixation of nitrogen by this process have only produced 30,000 tons per year instead of the calculated 300,000.

Table I gives the world's production of nitrogen contained in the products manufactured from 1913 to 1920. The figures represent thousands of tons.

Table I

Product	1913	1914	1915	1916	1917	1918	1919	1920
Chilean nitrate	430	382	273	452	467	416	251	391
Sulphate (coal)	290	225	275	116	200	240	260	285
Sulphate (synthetic)	7	31	63	114	180	200	120	140
Cyanamid	35	45	45	95	135	130	140	160
Nitric acid	10	11	11	11	18	25	28	28

Note One ton of nitrogen represents the nitrogen contents of 6.5 tons of sodium nitrate, or 5 tons of ammonium sulphate.

Table II

Maximum productive capacity in 1921 of different countries, in thousands of tons of nitrogen

Product	Chile	Germany and Austria	Great Britain	United States and Canada	Norway and Sweden	France and various	Totals	%
Chilean nitrate	520	520	33
Ammonium sulphate (coal)	...	105	95	100	...	140	440	27
Ammonium sulphate (synthetic)	...	300	300	19
Cyanamid	...	120	...	57	23	100	300	19
Nitric acid	1	28	1	30	2
Totals	520	525	95	158	51	141	1590	100

The output of cyanamid in Norway and Sweden is at present about 20,000 tons per annum. About 130,000 tons per annum of calcium nitrate is being produced by the electric-arc process.

The following figures show in percentages the relative position of Chilean nitrate and its competitors from 1894 to 1921; Chilean nitrate has been losing ground steadily:

	1894	1904	1913-1914	1921
Nitrate	% 73	% 60	% 56	% 33
Competitors	% 27	% 34	% 44	% 67

The only nitrogenous inorganic fertilizers employed in agriculture up to ten years ago were Chilean nitrate and ammonium sulphate. At the present time two more have reached appreciable figures in statistics: cyanamid and nitrate of calcium. To these must be added other ammoniacal salts, the intensive production of which is a direct result of the development of the explosives-making industries during the War, and various mixed salts and combinations produced with the intention of obtaining a complete fertilizer, that is to say, one containing nitrogen, phosphoric acid, and potash.

The nitrogenous inorganic fertilizers, classified according to decreasing percentage of nitrogen, are given in Table III.

Table III

	Nitrogen %	Phosphoric acid	Potash
Urea	46.1
Ammonium nitrate	34.0
Urea nitrate	34.0
Ammonium nitro-sulphate	27.0
Ammonium chloride	25.0
Ammonium sulphate	20.0
Calcium cyanamid	19.0
Ammonium carbonate	18.0
Ammonium nitrate (potassic)	16.0	...	8.0
Sodium nitrate	15.5
Calcium nitrate	13.0
Ammono-phos	15.0	12-14	...
Ammonium superphosphate	7.15	12-14	...
Ammonium superphosphate (mixed)	6.0	10-12	...

SALITRE, OR NITRATE OF SODA. Nitrate is suitable as a fertilizer for crops that are planted at a shallow depth. The soda is transformed into the carbonate, which is a useful corrective for acid soils; it liberates potash from its combinations when this is needed. *Per contra*, in argillaceous soils the sodium residue tends to make them heavier. Experience has shown that the continued use of saltpetre benefits soils. The efficiency of Chilean nitrate is recognized as high; it is always taken as the standard for comparison with other natural or synthetic fertilizers.

CALCIUM NITRATE. This fertilizer has similar applications to Chilean saltpetre. It contains calcium instead of sodium, and produces a strengthening effect in certain plants; soda is preferable for pastures and roots. It does not increase the heaviness of argillaceous soils, but its contents in lime are not sufficient to be taken into account because of their physical effects, which are the ones sought for when lime is added (5 or more tons per hectare) to soils which used it. The most serious disadvantage of calcium nitrate is its high hygroscopicity, which makes it necessary to ship it in hermetically sealed boxes; it must be used immediately. The efficiency of

calcium nitrate per unit of nitrogen is the same as that of Chilean nitrate; according to recent experiments, the latter gives an added yield of 3% in common rye and beet-root, and up to 27% in fodder-roots; calcium nitrate gives an added yield of 2% in potatoes, 5% in wheat, 9% in oats, and 10% in barley.

AMMONIUM SULPHATE. This fertilizer is not suitable for use in shallow-sown crops, except before sowing. Its effects are, as a general rule, as sure as those of saltpetre. Its efficiency is somewhat less, for it varies between 83 and 97%, and in exceptional cases as much as 75% of Chilean nitrate, according to the crops, the soils, and the experimenters. The sulphate of ammonia from gas-works is acid, and often contains elements that have a toxic effect on plants. Endeavors are being made to produce a neutral sulphate that may compete in purity with that derived from synthetic ammonia. There are especial cases where its efficiency is equal to that of Chilean nitrate; in the cultivation of rice the sulphate is superior.

CYANAMID. This cannot be used in shallow-sown crops. Its transformation in the soil is complex. It produces urea first, then ammonium carbonate, and lastly nitrate. It has several defects. The first is due to fineness; the second, to causticity, on account of the quicklime it contains; the third, because of losses of nitrogen. Cyanamid has been oiled, tarred, and granulated, without satisfactory result. The complexity of the decomposition of cyanamid in the soil causes its effects to be more varied and insecure than is the case with other nitrogenous fertilizers; the proper conditions for the use of cyanamid are yet unknown. According to experiments, which have lasted already more than ten years, the efficiency of cyanamid per unit is from 6% to 14% lower than that of sulphate of ammonia, and 17% to 25% lower than Chilean nitrate.

AMMONIUM NITRATE. This salt combines, theoretically, the advantages (rapidity of the first effect) with those of the sulphate (prolonged effects); its high degree of concentration results in an economy in freight. In actual practice it has serious drawbacks; it is explosive, it is hygroscopic, and it has a tendency to agglomerate. Its efficiency, according to experiments made in Great Britain during the War, is said, in certain cases, to have been superior to that of Chilean nitrate; but the results need confirmation.

AMMONIUM CHLORIDE. The effects and efficiency of this fertilizer are comparable with those of the sulphate. It is possible that, for financial reasons, this salt may prove a substitute for the sulphate in the utilization of ammonia obtained from coal.

AMMONIACAL SUPERPHOSPHATES. A product thus called in Germany is a simple mixture of the superphosphate of commerce with ammonium sulphate that contains 3 to 6% of nitrogen and 10 to 12% of phosphoric acid. It is usual to add up to 8% of potash in order to make a complete fertilizer. The true ammonium superphosphate is a salt that has been saturated with

ammonia gas by absorption and that contains from 6 to 8% of nitrogen and 12 to 14% of phosphoric acid. Efforts are being made in the United States to produce one that will contain from 10 to 16% of nitrogen and up to 40 or 50% of a suitable acid. Such would constitute an ideal universal fertilizer with which, owing to the high concentration of all its elements, the present charges for loading, transport, mixing, sacking, transshipment, and spreading on the soil would be reduced to the minimum.

Studies and experiments in this direction are being conducted in the United States and Germany, where such products have been put upon the market in small quantities as an experiment.

Mechanical Efficiency of Flotation-Machine Impellers

The Editor:

Sir—A method that has proved satisfactory in estimating the mechanical efficiency of flotation-machine impellers is to fill the machine with water until it overflows, then to empty it, measuring the water to obtain the total volume of the machine (*A*). Then run the machine with an impeller to be tested, adding water until an overflow is obtained. Stop the machine and empty it, to obtain the volume of water contained when running (*B*); *A* - *B* represents the volume of bubbles formed when running. Care must be taken that the water or solution used in each case is the same, otherwise the results will be vitiated by the difference in the frothing quality of the liquor. Different impellers can thus be compared.

The same method may prove of advantage in testing oils or other reagents, enabling results to be obtained without performing complete flotation tests with ore, and saving the cost and bother of assays, if complete tests are used to control such estimations. Correction must be made for the difference in volume of different impellers or baffles. By taking the original volume of the water in the machine as 100, and the running volume as a percentage of the original, different machines may be compared; the percentage frothed is of more interest than what remains. For instance, by running a 45° shrouded impeller backward, 21% was frothed; by running it forward, 36% was frothed; and by running it forward after the addition of eucalyptus oil, 47% was frothed. An impeller with four blades at 90°, shrouded, in water, frothed 35% of the original volume; an open impeller, not shrouded, with four blades at 30° from the horizontal frothed 32% of the original volume when eucalyptus was used. When it is desired to modify the intensity of frothing, this method of obtaining a numerical value of the result of change of such a factor as speed is of value.

ALFRED T. FRY.

Queenstown, Tasmania, September 23.

Use of Scrapers Underground

By Lucien Eaton

For the past ten years, and especially for the last five years, mechanical methods of loading ore underground have received increasing attention from mining men throughout the world. The number of designs of mechanical loaders that have been made is very large, and is continually increasing. Comparatively few of these machines have been successfully operated, and their field of operation, with a few exceptions, is limited to drifts and open stopes. Recently, however, some new types of mechanical loader have been developed that are said to be economical and effective when used on sub-levels. A good description of the various kinds of loaders manufactured was given by A. M. Gow in an article in the 'Engineering and Mining Journal', Vol. 109, No. 5, which covered the subject practically up to 1920.

One of the recent developments in mechanical loading underground is the use of 'scrapers' or 'slushers,' and this type of loader has been so successful, that, until the depression in the mining industry became severe, there was hardly a district in which experiments were not being carried on. In an article entitled 'The Use of Scrapers in Metal Mines,' published in the May 1921 number of the 'Compressed Air Magazine' (No. 5, Vol. XXV), I described some of the successful types of scrapers and the ways in which they were used, and discussed briefly the principles of their design.

For many years the horse-drawn 'slip-scraper' or 'slusher' has been in common use about mines for moving earth short distances on surface, but it was only with the development of small portable compressed-air hoists that its use underground was attempted. One of the first and most successful instances of its adaptation to underground conditions was at the Spruce-Adams mine of the Oliver Iron Mining Co., a producer of soft hematite ore on the Mesabi range at Eveleth, Minnesota. At this mine the ore is moved by 3½-ft. slushers (Fig. 1), pulled to the chute by Little Tugger air-hoists, and dumped by hand. The slusher is dragged back to the ore-pile by hand and filled in the usual manner. This method is extremely simple and flexible, and is very effective in finely divided material for distances up to fifty feet, but it entails extremely hard labor on the part of the man who handles the slusher. The rate of loading is from 10 to 14 tons per hour, and the production per man per shift is said to have been increased 23% over hand-shovelings.

It was seen quickly by those who experimented with the slip-scraper underground that, except under very favorable circumstances, the success of this method of moving ore depended upon the elimination of the continual walking back and forth with the scraper; therefore some means of loading and dumping the scraper

automatically was sought. The bottomless type of scraper, with or without sides, using a tail-rope, was the result. C. L. Lawton, manager for the Quiney Mining Co. at Hancock, Michigan, in the Lake Superior copper region, was one of the first to develop successfully a scraper of this type. He used a modification of the Bagley scraper (Fig. 2), having sides but no bottom, in open stopes for pulling broken ore down a foot-wall dipping between 30° and 40°. The scraper has two digging-edges, one equipped with teeth for use in coarse rock, and the other smooth, made of steel plate, for use in fine material. This scraper weighs over 400 lb. and is moved by a double-drum air-driven hoist with 5 by 6-in. cylinders, and moves about one ton of ore at each trip. It loads into ore-cars through chutes.

At about the same time, 1915, or possibly earlier, a bottomless scraper of a different type (Fig. 3) was developed in the lead-zinc districts of Missouri and Wisconsin. This scraper has no sides and is equipped with teeth. The usual motive-power is a double-drum geared hoist belted to an electric motor. Some large scrapers of this type have been built, and the tonnage moved has been remarkably large. The scrapers are used in open stopes and pits, usually dragging the ore into chutes.

A modification of the Joplin scraper just described was made by the engineers of the Calumet & Hecla Mining Co. in order to adapt it to their underground conditions. This scraper is shown in Fig. 4. It is large and heavy, weighing over 700 lb., and has been successfully used in stoping, in pulling ore down the foot-wall in stopes too flat for the ore to run by gravity, and in loading ears in drifts by dragging ore or rock up an incline. Similar scrapers have been used by several other mining companies in the same district. In using this scraper for loading ears in drifts a platform of 2-in. planks is built on a framework of 6-in. square timber high enough for cars to pass underneath and long enough for two to five cars. At the end nearest the breast there is an incline built of the same material on a slope of one foot in three, and a suitable hole is cut in the horizontal platform, through which the ore falls into the car below. A 6 by 9-in. double-drum geared hoist is mounted on the rear end of the platform, and the snatch-block for the tail-rope, or back-haul, is attached to a 4-in. bar or a sprag set in the breast. In order to ensure smooth travel for the scraper along the floor of the drift, rails are laid for it to slide upon. By this means 150 tons of rock per shift can be loaded and the radius of action increased to more than 125 feet.

An interesting loading arrangement planned for the Newport Mining Co. at Ironwood, Michigan, is a further development of the Calumet & Hecla practice. In loading

FIGURE 8

ore or rock in main-level drifts it is planned to use the cars themselves as a loading-platform. The cars are to be equipped with vertical extensions on the sides and with loose horizontal plates overlapping the ends, similar to those used on gravel-trains on railroads, where plows are used to remove road-ballast from flat cars. A small hoist is to be mounted on a flat car next to the electric locomotive, and an inclined iron apron is to be laid up to the end of the car nearest the breast. It will also be necessary to provide rods or straps running lengthwise on the tops of the cars to prevent the scraper from digging in as it passes over them. In operation the train will be backed close to the breast, a snatch-block will be hung from a bar across the breast, the hoist connected either to the trolley-wire or the air-line, and the incline adjusted to the end of the first car. The scraper will then be used to drag the broken ore up the incline into the cars, which will be filled successively. When the last car has been filled the scraper will be hauled upon the flat car with the hoist, the rope taken off the snatch-block and wound up, the incline taken down and the hoist disconnected from the power-line. The train will then proceed to the shaft, where the cars, which are gable-bottomed, will be dumped without uncoupling.

In the soft-ore mines on the Marquette range several types of scrapers have been used successfully. At the Isabella mine at Palmer, Michigan, Capt. T. J. Nicholas used a light scraper of the Quincy type for dragging ore down long raises that were too flat for the dirt to run by gravity. The unique part of this equipment was that he used a single-drum Little Tugger hoist with a dividing flange in the middle of the drum, and reversed the hoist when pulling the scraper back up the raise. The adjustment in the tail-rope for different positions of the snatch-block was obtained by means of a small drum attached to the back of the scraper. The loose end of the rope was wound on this drum and was paid out as the length of the haul increased.

Another modification of the Quincy type of scraper, shown in Fig. 5, has been successfully used at several mines for pulling ore and rock into chutes, and also for dragging it up an incline into a car. This scraper does not work well in coarse material.

The scrapers shown in Fig. 6 and 7 work better in coarse material, especially the latter, which is heavier and has the advantage of two digging edges, one of which is equipped with teeth for 'combing out the chunks'. This scraper is a favorite with the miners, and is suitable for both hard and soft ground. When loading into chutes these scrapers have a capacity of 30 tons per hour from 50 feet.

At the Cliffs Shaft mine of the Cleveland-Cliffs Iron Co., which is a producer of hard specular ore of high specific gravity, I was experimenting with scrapers up to the time the mine was closed, on June 1, 1921. The ore at this mine breaks into large pieces, which often weigh from 500 to 1000 lb., and is difficult to handle. Heavy equipment was necessary, but under favorable conditions excellent results were obtained. Two types of scrapers

were used, one with teeth and one without, sketches of which are shown in Fig. 8 and 9. The scraper with teeth worked best in large piles of coarse ore, and under favorable conditions loaded as much as 100 tons in an hour, dragging the ore into a chute.

Recently various types of scrapers have been put on the market for loading sand and gravel, some of which

FIGURE 11.

may prove successful underground. The four scrapers manufactured and sold by Sauerman Bros. of Chicago, shown in Fig. 10, were designed to stop digging as soon as full, and quite probably may be adapted to underground use. The Le Clair scraper is somewhat similar to one of the designs of scraper sold by the Goodman Mfg. Co. for loading coal underground. A description of the Goodman apparatus was given by Mr. Gow in his article referred to above, and in the Goodman Mfg. Co.'s handbook.

Although the hoe type of scraper is suitable for nearly all kinds of material, in its design account should be taken of the conditions under which it will have to work. The most important considerations are the angle of the cutting-edge, the weight of the bail, and the point of attachment of the haulage-rope. The maximum digging power will be obtained when the angle of the digging edge lies in the resultant of the pull and the force of gravity. It would seem simple to determine this angle, but unfortunately both of these forces are variables. The hauling force is usually applied approximately parallel with the surface of the broken ore, or, when hauling away from the pile, parallel with the floor of the drift, and from four to eight inches above it. The force of the pull, however, is not constant, being greatest when the scraper is taking its full load. The force of gravity as represented by the weight of the scraper is a constant, but the direction of its application with respect to the long axis of the scraper varies with the angle of the pile and the position of the scraper. It is quite evident from an inspection of Fig. 11 that the resultant of the forces exerted by gravity and by the pull of the hauling-rope is at a more acute angle with the line of pull, when the scraper is pulling material down-hill than when it is pulling it up-hill. The digging edge should vary accordingly. In practice the angle of the digging edge varies from 15° to 30° , and is usually about 20° . The same scraper may be adapted to different inclinations by having the point of attachment of the hauling-rope adjustable vertically in the same manner as is done with plows.

The bail should be so designed that it will slightly over-balance the weight of that part of the scraper that lies behind the cutting edge, so that no time will be lost in righting the scraper at the beginning of the forward pull. This is especially important in cleaning out the breasts of drifts. The hauling-rope should be attached to the bail at a point from four to eight inches above the floor. This is the position the front end of the bail will assume in operation, and it must therefore be taken into consideration in the design.

The weight of the scraper should be suited to the work it has to do, that is to say, to the size and weight of the pieces of broken ore, and to the amount of handling it will require. The size must be a compromise between capacity and portability. In general, I should say that a scraper should be about half as high as it is wide, in order to minimize the tendency toward overturning, and that the length should be roughly one and a half times

the width. The width varies in practice from 30 to 54 inches, and the weight from 160 to 1000 pounds.

The hoist best suited for hauling scrapers has been given much consideration of late. The larger scrapers, handling a ton or more at a trip, require engines of 15 to 30 hp. and speeds up to 400 ft. per minute. The engine should be capable of exerting its maximum pull at slow speeds, for, especially in coarse material, the scraper must have time to settle down between the chunks and take hold. If pulled too rapidly over the pile it will bounce from chunk to chunk without picking up a load. High speed is necessary after the scraper has left the pile, and also on the back-haul. The Lake Shore Engine Works, of Marquette, Michigan, builds a double-drum scraper-hoist with 6 by 9-in. cylinders that meets the requirements of large scrapers admirably. I have used successfully a double-drum Lidgerwood hoist with $6\frac{1}{4}$ by 8-in. cylinders, and re-built some of the No. 34 single-drum hoists of this make, substituting two narrow drums of 10-in. diameter for the standard 14-in. drum.

For the smaller scrapers, which are being used in soft ore and on sub-levels, a less powerful hoist is required. The Ingersoll-Rand Co. has designed and built an admirable little hoist for this work, which is called the 6-II Little Tugger. It is driven by compressed air and has a Doak engine developing about 5 hp. There are two drums loose on the shaft, with clutch and brake, with capacity for 250 ft. of $\frac{3}{8}$ -in. wire-rope. The maximum rope-speed is 200 ft. per minute, which is ample. The machine is very compact and weighs a little over 500 lb. The Sullivan Machinery Co. manufactures a small turbine-driven single-drum hoist of about the same capacity. Either this or the Waughhoist, manufactured by the Denver Rock Drill Mfg. Co., if equipped with double-drum, would be as good as the 6-II Little Tugger.

Of the electric hoists, the Lake Shore Engine Works and the Goodman Mfg. Co. have the only special designs that I know of. The Lake Shore electric hoist has a 7 hp., 220 v., d.-c. motor driving, through a worm-gear, two narrow drums which are equipped with strong friction-clutches. Its only drawback is its weight, which is about 1400 lb. It develops a pull of over 2000 lb. at a speed of 125 ft. per minute. In the Joplin district tandem double-drums are belted to an electric motor, the belt giving the slippage necessary to prevent burning out the motor when the scraper stalls.

There is a difference of opinion as to the superiority of having the drums in tandem or side by side on the same shaft. I rather favor the latter arrangement with narrow drums. In my article in the 'Compressed Air Magazine' I recommended having both drums loose on the shaft, with friction-clutches. Later experience leads me to believe that one drum may be tight on the shaft and the other need have only a jaw-clutch, provided the engine has a reversing-throttle. This makes the engine a single-lever machine, which can be operated, if necessary, by a one-armed man, and the cost of construction is considerably less than it is with two friction-clutches.

The small hoists are commonly mounted on 4-in. or

4½-in. posts, but they can be mounted on skids. The large hoists are mounted on skids or platforms. The snatch-block for the tail-rope is usually hung from a 3-in. bar set across the upper part of the drift close to the breast in drifting, and from a chain or wire-rope stretched between eye-bolts in open stopes. Additional snatch-blocks are often used when the hoist is not in position for a direct pull. The ordinary snatch-blocks are not strong enough for use with scrapers, but the special blocks built for skidding logs in lumbering operations give satisfactory service. The usual practice is to buy the sheave and have the mine blacksmith make the frame and hook.

The field of application of scrapers is wide, but they are especially suited for use in open pits, in open stopes, and in drifts. For milling ore into chutes and for dragging ore down open stopes or rooms where the foot-wall dips at less than 45° they are superior to any other device on the market. In drifting on sub-levels where the ore is dumped into chutes the use of scrapers has increased progress nearly 40%, with a corresponding decrease in the cost of labor. In stoping by the top-slicing method there is some difficulty in using scrapers on the side-slice, unless the first slice is carefully lagged, so as to keep the ore, as blasted, confined within the limits of the drift. It has also been found inexpedient to try to drag a scraper around a right-angle turn, but nearly the same result can be obtained by making two 45° turns one set apart, the side of the drift being planked up around the turn for a height of two feet. For this work the scraper should have for the tail-rope a back-bail, fastened to the rear corners, so that those corners will not catch on the timber in rounding the turn on the back-haul.

Like nearly all mechanical loaders, scrapers are not suitable for handling ore that has to be sorted as it is loaded. Experience has also shown that they are not particularly satisfactory in drifts where much water is dropping. I recall one case where a drift was being driven through soft ore, and a good deal of water was dropping from the back. The scraper dug unevenly in the bottom of the drift and piled loose dirt along the sides, so that it was impossible to keep a ditch open; and during the time when the miners were drilling and timbering the low spots in the drift filled with water, so that passage was difficult. After blasting, when the scraper was started, it would pull all the accumulated water into the chute, and the water would wash the ore out of the chute upon the track on the main level below.

The chief points of superiority of scrapers over most mechanical loaders are lower first cost, lower maintenance, and greater flexibility. The cost of operation seems to be about the same. The main disadvantage is that in drifting the drilling cannot be done while the scraper is in use. This is not necessarily the case in stopes.

There is a fairly wide variation in cost of operation. With the smaller outfits dragging ore forty to fifty feet the cost of loading is approximately half that of shovel-

ing, and about 5000 tons must be handled before the first cost has been earned, that is to say, the whole outfit will pay for itself in four to six months. The larger equipment makes a greater saving over hand-shoveling roughly proportional to its greater first cost and greater capacity, so that about the same length of time is required for it to pay for itself.

The use of scrapers underground is in its infancy, and, no doubt, when mining operations are resumed, a technique of its own will be developed, and new applications

FIG. 10. SAUERMAN SCRAPERS

discovered or worked out, which will be of great interest to the profession and value to the industry. Meanwhile an exchange of views on the subject by men who have been using scrapers will be a long step forward.

THE Bureau of Foreign and Domestic Commerce records imports of "flint, flints, and flint stones, underground", from several countries. These imports are partly pebbles for use in grinding-mills. The value of such imports during 1920 was \$338,630.

Time Studies in Metallurgical Analysis

By W. F. Dietrich

INTRODUCTION. This paper is a preliminary report on the application of detailed time studies to instruction in metallurgical analysis in the Department of Mining and Metallurgy of Stanford University, and is concerned chiefly with the utility of such studies as an aid to instruction. It is presented at this time in order to stimulate thought on the subject, in the hope that others will feel inclined to make similar studies with the object of obtaining eventually a set of standards for each important manipulation. Such time standards could be applied not only to instruction but also to plant practice, and would be especially desirable in determining the best procedure for a given determination. The standards given in this paper must not be considered as final, as they are the results of the first application of the method to student work in connection with this course.

THE COURSE IN METALLURGICAL ANALYSIS. This covers technical methods of analysis of copper, lead, zinc, iron, sulphur, insoluble, lime, magnesia, and silica. The course at present is open only to graduate students who have previously taken courses in qualitative and quantitative analysis (10 lectures and 150 laboratory hours in each). The time allotted to this course is 90 hours of laboratory work. A syllabus gives the schemes for the analytical methods to be used. The student is expected to memorize each scheme before using it, and to be prepared to answer questions on the theory of the method.

It has been found desirable at Stanford, as elsewhere, to give this work in the Metallurgy Department in order that students may have the opportunity to become sufficiently proficient to analyze the products of metallurgical tests without consuming an undue amount of time on the purely analytical work, thus leaving more time for actual testing. It is also important that the young metallurgist be well trained in metallurgical analysis in order that he may have a ready means of entering his chosen profession.

During the student's sojourn in American universities, generally, little or no attempt hitherto has been made to impress upon him the necessity for high personal efficiency in his daily life in order that he may accomplish the greatest amount of useful work in a given time. The extra class-work of the typical university course consists of a definite quantity of work to be completed, it is true, on a given date, but without particular reference to the time required by each individual to complete the assignment. For example, an assignment may be given that the instructor believes will require, say, four hours on the part of the average student. As a matter of fact, the time required by different students may vary from half an hour to eight hours (by no means an extreme case). When the papers are graded by the instructor the mark

given depends principally upon the quality and quantity of the work submitted, without regard to the time required to prepare the paper (excluding mathematics or similar papers that are graded solely on quality). If two students of equal ability spend a different amount of time on the same paper, the one spending the most time usually receives the highest mark. This rewards industry, but penalizes the student who judges accurately the proper amount of time necessary for him to grasp the essentials of the assignment and prepare his paper. It also penalizes the student who is carrying a heavy course or is 'working his way', or is interested in student activities. On the other hand, under this system of instruction the slow student is not helped to increase his personal efficiency. If he spends enough time on the assignment he may receive as high a mark as anyone in the class, and even be graduated from the university with honors. When this man enters industry he may find himself hopelessly inefficient, simply because he has never been trained to do his work in a reasonable time.

Considering the case of the exceptionally bright student, the tasks set to the average student are so easy for him that he finds plenty of surplus time for other things, and, only too often, fails to utilize his spare time in improving himself mentally or physically. He learns to take life easy, and when called upon after graduation for steady and severe work he may be found wanting. I believe that the above considerations account for most of the failures of honor-point men in industrial life.

With all this in mind it was early recognized that a course in metallurgical analysis, to justify it before those who might think the subject of too practical a nature to be taught in a university, must emphasize the elements of time and quantity, and require a degree of accuracy commensurate with the needs of industry. Therefore, 24 determinations (12 in duplicate) were decided upon as a unit, and the laboratory arranged accordingly. In general, the student is not permitted to work with less than this number of determinations at one time.

Each student is given personal instruction on each detail of manipulation, and is given the time standard that he should be able to attain on each operation when he acquires proficiency. At first, he reports his own time on total operations for each lot of determinations. These reports are not likely to give less than the actual time spent, even if the student were dishonest (which is rare), because a minimum of 90 hours is required, regardless of the minimum number of determinations completed. After the preliminary clumsiness is overcome, stop-watch studies of each manipulation are made and the student is frankly told his relative position with respect to the standards, and where in each operation he has lost either

time or motion. Special training is given on those operations in which the student is below the average. Toward the end of the course an 'all-day run' is given, which consists of the following determinations:

Element	Number, duplicate	Accuracy* % of element in assay	Method
Copper	1	0.5	Sulphocyanate permanganate
Lead	3	1.0	Volumetric molybdate
Zinc	2	1.0	Ferro cyanide
Iron	2	1.0	Stannous chloride reduction and permanganate titration
Sulphur	2	2.0	Nitro-chlorate solution and barium sulphate precipitation
Insoluble	1	2.0	From one of the iron determinations
	1	2.0	From one of the sulphur determinations

*These are extreme limits of error, and are subject to decrease on certain samples. Note that the accuracy is expressed as "% of element in assay", not in terms of absolute differences in percentage. The day's work includes mixing of samples and cleaning of all glassware used.

In rating the student, inaccurate results are taken into account as follows: Divide the total time (less unavoidable delays) by the number of determinations (28); multiply this factor by the number of incorrect results, and add the product to the elapsed time. The result is termed the time-accuracy rating of the student. Credit for the course is not given unless this rating is less than six hours. The reaction-time for the determinations given, that is, the time required for complete reactions and safe manipulation by an experienced man, is about 4 hours 30 minutes for our laboratory conditions, including everything from mixing samples to writing the report and washing glassware. Improvements in equipment already installed or contemplated will permit a reduction of perhaps 30 minutes in this time. That the method of calculating the time-accuracy rating has some justification is indicated by the result of two runs made by the same student, giving 4 hours 51 minutes with seven errors at one time, and 4 hours 48 minutes with one error the next time.

TIME STANDARDS. By way of illustration, some of the most important standards established thus far and the minimum, maximum, and average observed time for each operation are given in Table 1. The figures are based upon motion studies made of six different students
